A null-terminated string that is displayed by a web browser to indicate to the user which username and password they should use. If this parameter is NULL or an empty string, the domain name the client used to establish the connection will be used.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **RequireAuthentication** method can be used within an **OnCommand** event handler to indicate to the client that it must provide a username and password to access the requested resource. The client should respond by issuing another request that includes the required credentials. To determine if a client has included credentials with its request, use the **IsClientAuthenticated** method. The **GetClientCredentials** method will return the username and password that was provided by the client.

Some clients may require that the session be secure if authentication is requested or display warning messages to the user if the connection is not secure. It is recommended that you enable security using the HTTP_OPTION_SECURE option if your application will require clients to authenticate before accessing specific resources.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetClientCredentials, IsClientAuthenticated, SendResponse

CHttpServer::Restart Method

```
BOOL Restart();
```

Restart the server, terminating all active client sessions.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **Restart** method will restart the specified server, terminating all active client sessions. If the method is unable to restart the server for any reason, the server thread is terminated. The server retains all of the configuration parameters from the previous instance, however the statistical information (such as the number of clients, files transferred, etc.) will be reset.

If an application calls this method from within an event handler, the active client session (the client for which the event handler was invoked) may not get a disconnect notification. It is recommended that this method only be called by the same thread that created the server using the **Start** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

See Also

Start, Stop

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CHttpServer::Resume Method

```
BOOL Resume();
```

Resume accepting client connections.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **Resume** method instructs the server to resume accepting new client connections after the **Suspend** method has been called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

See Also

Restart, Start, Stop, Suspend, Throttle

CHttpServer::SendErrorResponse Method

```
BOOL SendErrorResponse(
   UINT nClientId,
   UINT nErrorCode,
   LPCTSTR lpszMessage
);
```

Send a customized error response to the specified client.

Parameters

nClientId

An unsigned integer which uniquely identifies the client session.

nErrorCode

An integer value that specifies the error code that should be sent to the client. This value should correspond to the error result codes defined for HTTP in RFC 2616, which are three-digit values in the range of 400 through 599. The method will fail if an invalid error code is specified.

lpszMessage

A null-terminated string that describes the error. If this parameter is NULL or specifies a zero-length string, a default message will be selected based on the error code.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **SendErrorResponse** method sends a response to the client indicating that an error has occurred, providing a numeric error code and HTML formatted text which may be displayed to the user. The *lpszMessage* parameter should provide a brief description of the error that will be included in the output sent to the client. Note that the message should not contain any special formatting control characters or HTML markup.

This method provides a simplified interface for sending an error response to the client. In some cases, a browser may choose to display its own error message to the user in place of the generic HTML document generated by this method. If you want your application to send a customized HTML document for a specific type of error, you should use the **SendResponse** method.

If you wish to redirect the client to use an alternate URL to access the requested resource, it is recommended that you use the **RedirectRequest** method rather than sending an error response.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

RedirectRequest, SendResponse

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CHttpServer::SendResponse Method

```
BOOL SendResponse(
   UINT nClientId,
   DWORD dwOptions,
   LPHTTPRESPONSE lpResponse,
   LPVOID lpvBuffer,
   DWORD dwLength
);
```

Send a response from the server to the specified client.

Parameters

nClientId

An unsigned integer which uniquely identifies the client session.

dwOptions

An unsigned integer which specifies how the client request data will be copied. It may be one of the following values:

Value	Description
HTTP_RESPONSE_DEFAULT	The ***lpvBuffer*** parameter is a pointer to a block of memory that contains the response data. The number of bytes of data that in the buffer is specified by the ***dwLength*** parameter. This is the same as specifying the HTTP_RESPONSE_MEMORY option.
HTTP_RESPONSE_MEMORY	The ***lpvBuffer*** parameter is a pointer to a block of memory that contains the response data. The number of bytes of data that in the buffer is specified by the ***dwLength*** parameter. The data will be sent to the client as a stream of bytes. If the server application was compiled using Unicode, it is responsibility of the application to convert any Unicode text to either ANSI or UTF-8, depending on the resource that was requested by the client.
HTTP_RESPONSE_STRING	The ***lpvBuffer*** parameter is a pointer to a string buffer that contains the response data. The maximum number of bytes of data that will be sent to the client is determined by the ***dwLength*** parameter. If the value of the ***dwLength*** parameter exceeds the string length, the value will be ignored and the contents of the string will be sent up to the terminating null character. If the Unicode version of this method is called, the string will be converted to a byte array before being sent to the client.
HTTP_RESPONSE_HGLOBAL	The ***lpvBuffer*** parameter is an HGLOBAL memory handle which references a block of memory that contains the response data. The number of bytes of data that in the buffer is specified by the ***dwLength*** parameter. The data will be sent to the client as a stream of bytes. It is the responsibility of the application to free the global memory

	handle after it is no longer needed.
HTTP_RESPONSE_FILE	The ***lpvBuffer*** parameter is a pointer to a string which specifies the name of a file that contains the response data. If the file does not exist, or does not specify a regular file, this method will fail. The ***dwLength*** parameter is ignored. If the content type for the specified file is not explicitly defined in the response, the method will attempt to automatically determine the correct type based on the file name extension and/or the contents of the file.
HTTP_RESPONSE_HANDLE	The ***lpvBuffer*** parameter is a handle to an open file and the ***dwLength*** parameter specifies the number of bytes to be read from the file and send to the client. If this option is specified, the response data will be read from the current position in the file and will advance the file pointer by the number of bytes sent to the client.
HTTP_RESPONSE_DYNAMIC	The response data will be generated dynamically. This prevents the content length from being included in the response header, and forces the connection to close, regardless if the keep-alive option has been specified. This option must be specified if the application wishes to use the **SendResponseData** method to send additional data to the client.
HTTP_RESPONSE_NOCACHE	Informs the client that the data being returned by the server should not be cached. Typically this is used in conjunction with the HTTP_RESPONSE_DYNAMIC option when the data is being generated dynamically.

lpResponse

A pointer to a **HTTPRESPONSE** structure which contains additional information about the response to the client. The structure that is passed by reference to this method must have the ***dwSize*** member initialized to the size of the structure or the method will fail. This parameter may be NULL, in which case a default response of "200 OK" is sent to the client along with any data specified by the ***lpvBuffer*** parameter.

lpvBuffer

The buffer that will contain any response data that should be sent to the client. The ***dwOptions*** parameter determines if this pointer references a block of memory, a null-terminated string buffer, a global memory handle or a file name. This parameter may be NULL, in which case no data will be sent to the client. If this method is called in response to a HEAD command being sent by the client, this parameter is ignored.

dwLength

An unsigned integer that specifies the number of bytes of data to be sent to the client. If the ***lpvBuffer*** parameter is NULL, this value must be zero. If this method is called in response to a HEAD command being sent by the client, this parameter is ignored.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **SendResponse** method is called within an **OnCommand** event handler to respond to the request made by the client. This method may only be called once after a command has been received, and must be called after the **ReceiveRequest** method. It is only necessary for the application to call this method if it wants to implement its own custom handling for a command. It is recommended that most applications use the default command processing for standard commands such as GET and POST to ensure that the appropriate security checks are performed and the response conforms to the protocol standard.

If the HTTP_RESPONSE_HANDLE option is used to read a copy of the response data from an open file, the handle must reference a disk file that was opened using the **CreateFile** function with GENERIC_READ access. It cannot be a handle to a device or named pipe. If the ***dwLength*** parameter is larger than the total number of bytes available to be read from the current position in the file, the method will stop sending data to the client when it reaches the end-of-file. If the method succeeds, the file pointer is advanced by the number of bytes of response data sent to the client. If the method fails, the file pointer is returned to its original position prior to the method being called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

CHttpServer::SendResponseData Method

```
INT SendResponseData(
   UINT nClientId,
   LPBYTE lpBuffer,
   INT nLength
);
```

Send additional data to the client in response to a command.

Parameters

nClientId

An unsigned integer which uniquely identifies the client session.

lpBuffer

A buffer that contains the response data that should be sent to the client. This parameter cannot be NULL.

nLength

An integer that specifies the number of bytes of data in the buffer. This value must be greater than zero.

Return Value

If the method succeeds, the return value is the number of bytes of data sent to the client. If the method fails, the return value is HTTP_ERROR. To get extended error information, call the **GetLastError** method.

Remarks

The **SendResponseData** method is called within a **OnCommand** event handler to send data to the client in response to a request. This method can only be used to send dynamically generated content after the **SendResponse** method has been called. The HTTP_RESPONSE_DYNAMIC option must have been specified when responding to the client or this method will fail.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

CHttpServer::SetCertificate Method

```
BOOL SetCertificate(
   DWORD dwProtocol,
   LPCTSTR lpszCertStore,
   LPCTSTR lpszCertName,
   LPCTSTR lpszPassword
);

BOOL SetCertificate(
   LPCTSTR lpszCertName,
   LPCTSTR lpszPassword
);
```

Set the name of the certificate to be used with secure connections.

Parameters

dwProtocol

A bitmask of supported security protocols. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_TLS	Either the TLS 1.2 or 1.3 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers which reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.

SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

lpszCertStore

A null-terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A null-terminated string which specifies the name of the certificate to use. The function will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the function will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the function will return an error indicating that the certificate could not be found.

lpszPassword

An optional pointer to a string which specifies the certificate owner's password. A value of NULL specifies that no password is required. This parameter is only required if the ***lpszCertStore*** parameter specifies a certificate file in PKCS #12 format that is password protected.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To

get extended error information, call the **GetLastError** method.

Remarks

An application only needs to call this method to support secure connections using TLS. When a certificate is specified, it must have a private key associated with it. Attempting to use a certificate which does not have a private key will result in an error during the startup process indicating that the server credentials are invalid.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The *lpszCertStore* parameter should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS #12.These certificate files typically have an extension of .pfx or .p12. If a password was specified when the certificate was created, it must be provided in the *lpszPassword* parameter or the class will be unable to access the certificate.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetOptions, SetOptions

CHttpServer::SetClientAccess Method

```
BOOL SetClientAccess(
   UINT nClientId,
   DWORD dwUserAccess
);
```

Change the access rights associated with the specified client session.

Parameters

nClientId

An unsigned integer which uniquely identifies the client session.

dwUserAccess

An unsigned integer which specifies one or more user access rights. For a list of user access rights that can be granted to the client, see User and File Access Constants.

Return Value

If the method succeeds, the return value is non-zero. If the client ID does not specify a valid client session, the method will return zero. This method can only be used with authenticated clients. If the client session has not been authenticated, the return value will be zero.

Remarks

The **SetClientAccess** method can change multiple access rights for the client session. The **EnableClientAccess** method can be used to grant or revoke a specific permission for the client session.

If the *dwUserAccess* parameter has a value of HTTP_ACCESS_DEFAULT, then default permissions will be granted to the client session based on the configuration of the server. This is the recommended value for most clients. It is important to consider the implications of changing the access permissions granted to a client session. For example, if you do not grant clients HTTP_ACCESS_READ permission, it can effectively disable the site because the server will return 403 Forbidden errors for all GET and HEAD requests.

This function should typically be called in the **OnConnect** event handler to assign general permissions to the client, or in the **OnCommand** event handler after the client has issued a request and provided any authentication credentials that are required.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

See Also

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CHttpServer::SetClientHeader Method

```
BOOL HttpSetClientHeader(
   UINT nClientId,
   UINT nHeaderType,
   LPCTSTR lpszHeaderName,
   LPCTSTR lpszHeaderValue
);
```

Create or change the value of a request or response header for the client session.

Parameters

nClientId

An unsigned integer which uniquely identifies the client session.

nHeaderType

Specifies the type of header to create or modify. It may be one of the following values:

Value	Description
HTTP_HEADERS_REQUEST	Change a request header that was provided by the client. Request header values provide additional information to the server about the type of request being made.
HTTP_HEADERS_RESPONSE	Change a response header that was created by the server. Response header values provide additional information to the client about the type of information that is being returned by the server.

lpszHeaderName

A null-terminated string that specifies the name of the header that should be created or modified. Header names are not case-sensitive and should not include the colon which acts as a delimiter that separates the header name from its value. This parameter cannot be a NULL pointer or an empty string.

lpszHeaderValue

A null-terminated string that specifies the new value of the header. If this parameter is a NULL pointer or an empty string, it has the same effect as deleting the header value from the list of request or response headers.

Return Value

If the method succeeds, the return value is non-zero. If the client ID does not specify a valid client session, the method will return zero. If the method fails, the **GetLastError** method will return more information about the last error that has occurred.

Remarks

The **SetClientHeader** method will change the value of a request or response header for the specified client session. If the *lpszHeaderName* value matches an existing header field, its value will be replaced. If the header name is not defined, then a new header will be created with the given value. You should not change the value of most standard response header values unless you are certain of the impact that it would have on the normal operation of the client.

If you wish to define a custom header value that would be included in the response to a client request,

you should prefix the header name with "X-" to avoid potential conflicts with the standard response headers. For example, if you wanted to identify a customer, you could create a header field with the name "X-Customer-ID" and set the value to the customer ID number. The client application would receive this custom header value as part of the response to its request for a document.

Refer to Hypertext Transfer Protocol Headers for a list of common request and response headers that are used.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

DeleteClientHeader, GetClientHeader

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CHttpServer::SetClientIdleTime Method

```
UINT SetClientIdleTime(
   UINT nClientId,
   UINT nTimeout
);
```

Change the idle timeout period for the specified client session.

Parameters

nClientId

An unsigned integer which uniquely identifies the client session.

nTimeout

An unsigned integer value that specifies the number of seconds that the client may remain idle. If this value is zero, the default idle timeout period for the server will be used.

Return Value

If the method succeeds, the return value is the previous client idle timeout period in seconds. If the client ID does not specify a valid client session, the method will return zero.

Remarks

The **SetClientIdleTime** method is will change the number of seconds that the client may remain idle before being automatically disconnected by the server. The minimum timeout period for a client is 10 seconds, the maximum is 300 seconds (5 minutes). The idle time of a client session is based on the last time a command was issued to the server or when a data transfer completed.

If the value INFINITE is specified as the timeout period, the client activity timer will be refreshed, extending the idle timeout period for the session. This is typically done inside an **OnTimeout** event handler to prevent the client from being disconnected due to inactivity.

To obtain the current idle timeout period for a client, along with the amount of time the client has been idle, use the **GetClientIdleTime** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

See Also

GetClientIdleTime

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CHttpServer::SetClientVariable Method

```
BOOL HttpSetClientVariable(
   UINT nClientId,
   LPCTSTR lpszName,
   LPCTSTR lpszValue
);
```

Create or change the value of a CGI environment variable for the specified client.

Parameters

nClientId

An unsigned integer which uniquely identifies the client session.

lpszName

A null-terminated string that specifies the name of the environment variable that should be created or modified. Environment variables are not case-sensitive and should not include the equal sign which acts as a delimiter that separates the variable name from its value. This parameter cannot be a NULL pointer or an empty string.

lpszValue

A null-terminated string that specifies the new value of the environment variable. If this parameter is a NULL pointer or an empty string, it has the same effect as deleting the variable from the environment block for the client session.

Return Value

If the method succeeds, the return value is non-zero. If the client ID does not specify a valid client session, the method will return zero. If the method fails, the **GetLastError** method will return more information about the last error that has occurred.

Remarks

The **SetClientVariable** method will change the value of a environment variable for the specified client session. If the *lpszName* value matches an existing variable, its value will be replaced. If the variable is not defined, then a new variable will be created with the given value. The value of an environment variable can be obtained using the **GetClientVariable** method.

The server will automatically create a number of different environment variables that will be passed to a program or script executed by the server. These variables are defined in RFC 3875 as part of the Common Gateway Interface (CGI) 1.1 specification. The following variables are defined by the server and should not be modified directly by the application:

Variable Name	Description
AUTH_TYPE	The authorization scheme used by the server to authenticate the client session
CONTENT_LENGTH	The length of the request data provided by the client
CONTENT_TYPE	The MIME type that identifies the type of content provided by the client
DOCUMENT_ROOT	The full path to the local document root directory on the server
GATEWAY_INTERFACE	The version of the Common Gateway Interface that is being used by the server

PATH_INFO	The resource or sub-resource that is to be returned by the program or script
PATH_TRANSLATED	The path information mapped to the server root document directory structure
QUERY_STRING	The URL encoded query parameters passed to the program or script
REMOTE_ADDR	The network address of the client sending the request to the server
REMOTE_HOST	The same value as the REMOTE_ADDR variable
REMOTE_USER	The username specified as part of the authentication credentials provided by the client
REQUEST_METHOD	The method used by the client to request the resource
REQUEST_URI	The URI for the script provided by the client
SCRIPT_FILENAME	The full path to the program or script on the server
SCRIPT_NAME	The path to the program or script specified by the client
SERVER_NAME	The hostname or IP address of the server that the client connected to
SERVER_PORT	The port number that the client used to connect to the server
SERVER_PORT_SECURE	This variable has a value of "1" if the client connection to the server is secure
SERVER_PROTOCOL	The version of the server protocol used
SERVER_SOFTWARE	The server identity string which specifies the application name and version

In addition to the environment variables listed, the server will also create variables that are prefixed with "HTTP_" that are set to the value of request headers that are not otherwise defined. For example, the HTTP_USER_AGENT variable will be set to the value of the User-Agent header provided by the client as part of the request.

Calling the **SetClientVariable** method within an **OnExecute** event handler will have no effect because it occurs after the CGI program or script has completed execution. To create or modify environment variables for the client session, it should be done within an **OnCommand** event handler.

This method will not change the environment block for the server process. Each client session is allocated its own private environment block which is inherited by the CGI program. When the client session terminates, the memory allocated for its environment is released.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

GetClientVariable

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CHttpServer::SetCommandFile Method

```
BOOL SetCommandFile(
   UINT nClientId,
   LPCTSTR lpszFileName
);
```

Change the name of a file or directory that is the target of the current command.

Parameters

nClientId

An unsigned integer which uniquely identifies the client session.

lpszFileName

A null-terminated string that specifies the new file name. This parameter may be NULL to specify that the original file or directory name should be used.

Return Value

If the method succeeds, the return value is non-zero. If the client ID does not specify a valid client session, the method will return zero.

Remarks

The **SetCommandFile** method is used by the application to change the target file or directory name for the current command from within an **OnCommand** event handler. This can be used to effectively redirect the client to use a different file than the one that was actually requested. For example, if the client issues the GET command to download a file from the server, this method can be used to redirect the command to use a different file name. To obtain the full path to the file or directory that is the target of the current command, use the **GetCommandFile** method.

The *lpszFileName* parameter specifies the path to the new file or directory name. If the path is absolute, then it will be used as-is. If the path is relative, it will be relative to the root directory for the client session. Because the root document directory for the client can depend on the hostname that the client used when connecting to the server, it is recommended that you always use an absolute path. The full path to this file is not limited to the server root directory or its subdirectory, it can specify a file anywhere on the local system. If this parameter is a NULL pointer, or points to an empty string, then the server will revert to using the actual file or directory name specified by the command. This enables the application to effectively undo a previous call to this method to change the target file name.

Typically this method would be used to redirect a client to a file or directory that it may not normally have access to. Exercise caution when using this method to provide access to data that is stored outside of the server root directory. Incorrect use of this method could expose the server to security risks or cause unpredictable behavior by client applications. In most cases it is preferable to use the **AddVirtualPath** method to create a virtual path or file name on the server, or the **RedirectRequest** method to request the client use a different URL to access the resource.

This method should only be called within the context of the **OnCommand** event, and only for those commands that perform an action on a file or directory. If the current command does not target a file or directory, this method will return zero and the last error code will be set to ST_ERROR_INVALID_COMMAND.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

AddVirtualPath, GetCommandFile, ReceiveRequest, RedirectRequest, SendResponse

CHttpServer::SetDirectory Method

```
BOOL SetDirectory(
   LPCTSTR lpszDirectory
);
```

Specify the local directory that will be used as the server root directory.

Parameters

lpszDirectory

A null-terminated string that specifies the root directory for the server. If this parameter is NULL or a zero-length string, the server will use the current working directory as the root directory.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it will return zero.

Remarks

The **SetDirectory** method specifies the path to the local directory that should be used as the root document directory for the server.

You cannot change the server root directory after the server has started. To change the root directory, you must stop the server using the **Stop** method and then start another instance of the server with a configuration that specifies the new directory.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetDirectory

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CHttpServer::SetIdentity Method

```
BOOL SetIdentity(
   LPCTSTR lpszIdentity
);
```

Change the identity of the specified server.

Parameters

lpszIdentity

A null-terminated string that identifies the server. If this parameter is NULL or specifies an empty string, the current identity for the server is reset to a default value. The maximum length of the identity string is 64 characters, including the terminating null character.

Return Value

If the method succeeds, the return value is non-zero, otherwise it will return a value of zero.

Remarks

The **SetClientIdentity** method changes a string value used by the server to identify itself to clients. The identity string does not have any standard format and is used for informational purposes only. Typically it consists of the application name and a version number. Changing the server identity has no effect on the operation of the server. To obtain the identity string currently associated with the server, use the **GetIdentity** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetIdentity

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CHttpServer::SetLastError Method

```
VOID SetLastError(
   DWORD dwError
);
```

Set the last error code for the specified server session.

Parameters

dwError

An unsigned integer that specifies an error code.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each server session. Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_SERVER or HTTP_ERROR.

If the ***dwError*** parameter is specified with a value of zero, this effectively clears the error code for the last method that failed. Those methods which clear the last error code when they succeed are noted on their reference page.

Applications can retrieve the value saved by this method by calling the **GetLastError** method to determine the specific reason for failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

See Also

GetCommandResult, GetLastError, SendResponse

CHttpServer::SetLogFile Method

```
BOOL SetLogFile(
   UINT nLogFormat,
   UINT nLogLevel,
   LPCTSTR lpszFileName
);
```

Change the current log format, level of detail and file name.

Parameters

nLogFormat

An integer value that specifies the format used when creating or updating the server log file. The following formats are supported:

Value	Description
HTTP_LOGFILE_NONE	This value specifies that the server should not create or update a log file.
HTTP_LOGFILE_COMMON	This value specifies that the log file should use the common log format that records a subset of information in a fixed format. This log format usually only provides information about GET, PUT and POST requests.
HTTP_LOGFILE_COMBINED	This value specifies that the server should use the combined log file format. This format is similar to the common format, however it includes the client referrer and user agent. This is the format that most Apache web servers use by default.
HTTP_LOGFILE_EXTENDED	This value specifies that the log file should use the standard W3C extended log file format. This is an extensible format that can provide additional information about the client session. This format typically generates the largest logfiles.

nLogLevel

An integer value that specifies the level of detail that should generated in the log file. The minimum value is 1 and the maximum value is 10. If this parameter is zero, it is the same as specifying a log file format of HTTP_LOGFILE_NONE and will disable logging by the server.

lpszFileName

A null-terminated string that specifies the name of the log file that should be created or appended to. If the server was configured with logging enabled and this parameter is NULL or an empty string, the current log file name will not be changed. If the log file does not exist, it will be created. If it does exist, the contents of the log file will be appended to.

Return Value

If the method succeeds, the return value is non-zero. If one of the parameters are invalid, the method will return zero.

Remarks

The **SetLogFile** method can be used to change the current log file name, the format of the log file or the level of detail recorded in the log file. In some situations it may be desirable to delete the current

log file contents when changing the format or ensure that a new log file is created. To do this, combine the ***nLogFormat*** parameter with the constant HTTP_LOGFILE_DELETE.

The higher the value of the ***nLogLevel*** parameter, the greater the level of detail that is recorded by the server. A log level of 1 instructs the server to only record GET, POST and PUT requests, while a level of 10 instructs the server to record all commands processed by the server. Because a higher level of logging detail can negatively impact the performance of the server, it is recommended that you do not exceed a level of 5 for most applications. A log level of 10 should only be used for debugging purposes.

Example

```
UINT nLogFormat = HTTP_LOGFILE_NONE;
UINT nLogLevel = 0;
UINT nNewLevel = 5;
BOOL bChanged = FALSE;

// Change the level of detail for the current log file if logging
// has been enabled and the current level is a lower value

if (pHttpServer->GetLogFile(&nLogFormat, &nLogLevel, NULL, 0))
{
    if (nLogFormat != HTTP_LOGFILE_NONE && nLogLevel < nNewLevel)
        bChanged = pHttpServer->SetLogFile(nLogFormat, nNewLevel, NULL);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetLogFile, RenameServerLogFile

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CHttpServer::SetName Method

```
BOOL SetName(
   UINT nClientId,
   LPCTSTR lpszHostName
);
```

Change the host name assigned to the specified server or client session.

Parameters

nClientId

An unsigned integer which uniquely identifies the client session. This value may be zero.

lpszHostName

A null-terminated string that specifies the new host name assigned to the server or client session. If this value is NULL or points to an empty string, the current host name will be changed to use the default host name.

Return Value

If the method succeeds, the return value is non-zero. If the client ID is invalid, or the buffer is not large enough to store the complete hostname, the method will return a value of zero.

Remarks

This method will change the host name assigned to the specified client session. If the ***nClientId*** parameter has a value of zero, the method will change default host name that was assigned to the server as part of the server configuration. If the ***nClientId*** parameter specifies a valid client session and the ***lpszHostName*** parameter is NULL, the host name associated with the client session will be changed to the current host name assigned to the server.

When a client connects to the server, it can specify the host name that it used to establish the connection by sending the HOST command. This is typically used with virtual hosting, where one server may accept client connections for multiple domains. The **GetName** method will return the host name specified by the client, and **SetName** can be used by the application to either explicitly assign a different host name to the client session, or override the host name provided by the client.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetAddress, GetName

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CHttpServer::SetOptions Method

```
BOOL SetOptions(
   DWORD dwOptions
);
```

Sets the default options for this instance of the server.

Parameters

dwOptions

An unsigned integer which specifies one or more options. For a list of available options, see Server Option Constants.

Return Value

If the method is successful, it will return a non-zero value, otherwise it will return a value of zero.

Remarks

The **SetOptions** method changes the default options for the current instance of the server. This method cannot be used to change the options for an active instance of the server. If the server is active, it must be stopped before calling this method. To get the current options, use the **GetOptions** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

See Also

GetOptions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CHttpServer::SetPriority Method

```
INT SetPriority(
   INT nPriority
);
```

Change the priority assigned to the specified server.

Parameters

nPriority

An integer value which specifies the new priority for the server. It may be one of the following values:

Value	Description
HTTP_PRIORITY_BACKGROUND	This priority significantly reduces the memory, processor and network resource utilization for the server. It is typically used with lightweight services running in the background that are designed for few client connections. The server thread will be assigned a lower scheduling priority and will be frequently forced to yield execution to other threads.
HTTP_PRIORITY_LOW	This priority lowers the overall resource utilization for the server and meters the processor utilization for the server thread. The server thread will be assigned a lower scheduling priority and will occasionally be forced to yield execution to other threads.
HTTP_PRIORITY_NORMAL	The default priority which balances resource and processor utilization. This is the priority that is initially assigned to the server when it is started, and it is recommended that most applications use this priority.
HTTP_PRIORITY_HIGH	This priority increases the overall resource utilization for the server and the thread will be given higher scheduling priority. It is not recommended that this priority be used on a system with a single processor.
HTTP_PRIORITY_CRITICAL	This priority can significantly increase processor, memory and network utilization. The server thread will be given higher scheduling priority and will be more responsive to client connection requests. It is not recommended that this priority be used on a system with a single processor.

Return Value

If the method succeeds, the return value is the previous priority assigned to the server. If the method fails, the return value is HTTP_PRIORITY_INVALID. To get extended error information, call the **GetLastError** method.

Remarks

The **SetPriority** method can be used to change the current priority assigned to the specified server. Client connections that are accepted after this method is called will inherit the new priority as their

default priority. Previously existing client connections will not be affected by this method.

Higher priority values increase the thread priority and processor utilization for each client session. You should only change the server priority if you understand the impact it will have on the system and have thoroughly tested your application. Configuring the server to run with a higher priority can have a negative effect on the performance of other programs running on the system.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h.
Import Library: cshtsv12.lib

See Also

GetPriority, Start

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CHttpServer::SetStackSize Method

```
BOOL SetStackSize(
   DWORD dwStackSize
);
```

Change the initial size of the stack allocated for threads created by the server.

Parameters

dwStackSize

The amount of memory that will be committed to the stack for each thread created by the server. If this value is zero, a default stack size will be used.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **SetStackSize** method changes the initial amount of memory that is committed to the stack for each thread created by the server. By default, the stack size for each thread is set to 256K for 32-bit processes and 512K for 64-bit processes. Increasing or decreasing the stack size will only affect new threads that are created by the server, it will not affect those threads that have already been created to manage active client sessions. It is recommended that most applications use the default stack size.

You should not change the stack size unless you understand the impact that it will have on your system and have thoroughly tested your application. Increasing the initial commit size of the stack will remove pages from the total system commit limit, and every page of memory that is reserved for stack cannot be used for any other purpose.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

See Also

GetMemoryUsage, GetStackSize, Start

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CHttpServer::SetUuid Method

```
BOOL SetUuid(
   LPCTSTR lpszHostUuid
);
```

Assign a UUID to the current instance of the server.

Parameters

lpszHostUuid

A null-terminated string that specifies the server UUID, terminated with a null character. This value can be used when storing information about the server, and should be generated using a utility such as **uuidgen** which is included with Visual Studio. This parameter may be NULL or point to an empty string, in which case a temporary UUID will be randomly generated for the server.

Return Value

If the method succeeds, the return value is non-zero, otherwise the method return a value of zero.

Remarks

The **SetUuid** method assigns a Universally Unique Identifier (UUID) to the server. The UUID may either be generated by the application and assigned as part of the server configuration, or an ephemeral UUID may be automatically generated when the server is started. This method cannot be used to change the UUID after the server has been started. To determine the UUID assigned to an active server instance, use the **GetUuid** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetUuid

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CHttpServer::Start Method

```
BOOL Start(
   LPCTSTR lpszLocalHost,
   UINT nLocalPort,
   DWORD dwOptions
);

BOOL Start(
   LPCTSTR lpszLocalHost,
   UINT nLocalPort
);

BOOL Start(
   UINT nLocalPort
);
```

The **Start** method begins listening for client connections on the specified local address and port number. The server is started in its own thread and manages the client sessions independently of the calling thread. All interaction with the server and its client sessions takes place inside the class event handlers.

Parameters

lpszLocalHost

A null-terminated string which specifies the local hostname or IP address address that the server should be bound to. If this parameter is omitted or specifies a NULL pointer an appropriate address will automatically be used. If a specific address is used, the server will only accept client connections on the network interface that is bound to that address.

nLocalPort

The port number the server should use to accept client connections. If a value of zero is specified, the server will use the standard port number 21 to listen for connections, or port 990 if the server is configured to use implicit TLS. The port number used by the application must be unique and multiple instances of a server cannot use the same port number. It is recommended that a port number greater than 5000 be used for private, application-specific implementations.

dwOptions

An unsigned integer value that specifies one or more options to be used when creating an instance of the server. For a list of the available options, see Server Option Constants. If this parameter is omitted, the default options for the server instance will be used.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

In most cases, the ***lpszLocalHost*** parameter should be omitted or a NULL pointer. On a multihomed system, this will enable the server to accept connections on any appropriately configured network adapter. Specifying a hostname or IP address will limit client connections to that particular address. Note that the hostname or address must be one that is assigned to the local system, otherwise an error will occur.

If an IPv6 address is specified as the local address, the system must have an IPv6 stack installed and

configured, otherwise the method will fail.

To listen for connections on any suitable IPv4 interface, specify the special dotted-quad address "0.0.0.0". You can accept connections from clients using either IPv4 or IPv6 on the same socket by specifying the special IPv6 address "::0", however this is only supported on Windows 7 and Windows Server 2008 R2 or later platforms. If no local address is specified, then the server will only listen for connections from clients using IPv4. This behavior is by design for backwards compatibility with systems that do not have an IPv6 TCP/IP stack installed.

The handle returned by this method references the listening socket that was created when the server was started. The service is managed in another thread, and all interaction with the server and active client connections are performed inside the event handlers. To disconnect all active connections, close the listening socket and terminate the server thread, call the **Stop** method.

The host UUID that is defined as part of the server configuration should be generated using the **uuidgen** utility that is included with the Windows SDK. You should not use the UUID that is provided in the example code, it is for demonstration purposes only. If no host UUID is specified in the server configuration, an ephemeral UUID will be generated automatically when the server is started.

Example

```
CHttpServer *pHttpServer = new CHttpServer();

// Initialize the server configuration
pHttpServer->SetName(_T("server.company.com"));
pHttpServer->SetUuid(_T("10000000-1000-1000-1000-100000000000"));
pHttpServer->SetDirectory(_T("%ProgramData%\\MyProgram\\Server"));
pHttpServer->SetLogFile(HTTP_LOGFILE_EXTENDED, 5,
_T("%ProgramData%\\MyProgram\\Server.log"));
pHttpServer->SetOptions(HTTP_SERVER_DEFAULT);

// Start the server
pHttpServer->Start(HTTP_PORT_DEFAULT);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

EnumClients, Restart, Stop

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CHttpServer::Stop Method

```
BOOL Stop();
```

Stop the server, terminating all active client sessions and releasing the resources that were allocated for the server.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero.

Remarks

The **Stop** method instructs the server to stop accepting client connections, disconnects all active client connections and terminates the thread that is managing the server session. The handle is no longer valid after the server has been stopped and should no longer be used. Note that it is possible that the actual handle value may be re-used at a later point when a new server is started. An application should always consider the server handle to be opaque and never depend on it being a specific value.

If an application calls this method from within an event handler, the active client session (the client for which the event handler was invoked) may not get a disconnect notification. It is recommended that this method only be called by the same thread that created the server using the **Start** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

See Also

Restart, Start

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CHttpServer::Suspend Method

```
BOOL Suspend();
```

Suspend the server and reject new client connections.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **Suspend** method instructs the server to suspend accepting new client connections. Any incoming client connections will be rejected with an error message indicating that the server is currently unavailable. To resume accepting client connections, call the **Resume** method. Suspending the server will have no effect on clients that have already established a connection with the server.

It is recommended that you only suspend a server if absolutely necessary, and only for brief periods of time. If you want to limit the number of active client connections or control the connection rate for clients, use the **Throttle** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

See Also

Restart, Resume, Start, Stop, Throttle

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CHttpServer::Throttle Method

```
BOOL Throttle(
   UINT nMaxClients,
   UINT nMaxClientsPerAddress,
   DWORD dwConnectionRate
);
```

The **Throttle** method limits the number of active client connections, connections per address and connection rate.

Parameters

nMaxClients

A value which specifies the maximum number of clients that may connect to the server. A value of zero specifies that there is no fixed limit to the number of client connections.

nMaxClientsPerAddress

A value which specifies the maximum number of clients that may connect to the server from the same IP address. A value of zero specifies that there is no fixed limit to the number of client connections per address. By default, there is a limit of four client connections per address.

dwConnectionRate

A value which specifies a restriction on the rate of client connections, limiting the number of connections that will be accepted within that period of time. A value of zero specifies that there is no restriction on the rate of client connections. The higher this value, the fewer the number of connections that will be accepted within a specific period of time. By default, there is no limit on the client connection rate.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **Throttle** method is used to limit the number of connections and the connection rate to minimize the potential impact of a large number of client connections over a short period of time. This can be used to protect the server from a client application that is malfunctioning or a deliberate denial-of-service attack in which the attacker attempts to flood the server with connection attempts.

If the maximum number of client connections or maximum number of connections per address is exceeded, the server will reject subsequent connection attempts until the number of active client sessions drops below the specified threshold. Note that adjusting these values lower than the current connection limits will not affect clients that have already connected to the server. For example, if the **Start** method is called with the maximum number of clients set to 100, and then **Throttle** is called lowering that value to 75, no existing client connections will be affected by the change. However, the server will not accept any new connections until the number of active clients drops below 75.

Increasing the connection rate value will force the server to slow down the rate at which it will accept incoming client connection requests. For example, setting this parameter to a value of 1000 would limit the server to accepting one client connection every second, while a value of 250 would allow the server to accept four client connections per second. Note that significantly increasing the amount of time the server must wait to accept client connections can exceed the connection backlog queue, resulting in client connections being rejected.

It is recommended that you always specify conservative connection limits for your server application based on expected usage. Allowing an unlimited number of client connections can potentially expose the system to denial-of-service attacks and should never be done for servers that are accessible over the Internet.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

See Also

Restart, Resume, Start, Suspend

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CHttpServer Event Handlers

Method	Description
OnAuthenticate	The client requested authentication
OnConnect	The client established a control connection to the server
OnCommand	The client issued a command to the server
OnDisconnect	The client has disconnected from the server
OnDownload	The client has downloaded a file from the server
OnError	The event handler encountered an error when processing a client event
OnExecute	The client has executed an external program on the server
OnResult	The command issued by the client has been processed by the server
OnTimeout	The client has exceeded the maximum allowed idle time
OnUpload	The client has uploaded a file to the server

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CHttpServer::OnAuthenticate Method

```
virtual void OnAuthenticate(
   UINT nClientId,
   LPCTSTR lpszHostName,
   LPCTSTR lpszUserName,
   LPCTSTR lpszPassword
);
```

A virtual method that is invoked after the client has successfully downloaded a file from the server.

Parameters

nClientId

An unsigned integer which uniquely identifies the client session.

lpszHostName

A null-terminated string that specifies the host name that the client used to establish the connection.

lpszUserName

A null-terminated string that specifies the user name provided by the client.

lpszPassword

A null-terminated string that specifies the cleartext user password provided by the client.

Return Value

None.

Remarks

The **OnAuthenticate** event handler is invoked when the client has provided authentication credentials as part of the request for a document or other resource. To implement an event handler, the application should create a class derived from the **CHttpServer** class, and then override this method.

The event handler can call the **AuthenticateClient** method to authenticate the client session. If the event handler does not authenticate the client, the server will perform its default authentication. To reject the credentials provided by the client, use the **SendErrorResponse** method with a result code of 401.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

OnCommand, OnConnect

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CHttpServer::OnCommand Method

```
virtual void OnCommand(
   UINT nClientId,
   LPCTSTR lpszCommand,
   LPCTSTR lpszResource,
   LPCTSTR lpszParameters,
   BOOL& bHandled
);
```

A virtual method that is invoked after the client has sent a command to the server.

Parameters

nClientId

An unsigned integer which uniquely identifies the client session.

lpszCommand

A null-terminated string that specifies the command issued by the client. The command name will always be capitalized. For a complete list of commands supported by the server, see Server Commands.

lpszResource

A null-terminated string that specifies the resource that the client has requested. Depending on the command issued, it may be a document, a folder or an executable script.

lpszParameters

A null-terminated string that specifies any query parameters that have been provided by the client. The string will be empty if there were no query parameters included with the request. The query parameters in this string will be URL encoded.

bHandled

An integer value that indicates whether the handler has processed the event. If the handler sets this parameter to a non-zero value, it indicates that the application has processed the command itself. If this parameter has a value of zero, then the server will perform the default action for the command. By default, this parameter has a value of zero.

Return Value

None.

Remarks

The **OnCommand** event handler is invoked after the client has sent a command to the server, but before the command has been processed. To implement an event handler, the application should create a class derived from the **CHttpServer** class, and then override this method.

This event handler is invoked for all commands issued by the client, including invalid or disabled commands. If the ***bHandled*** parameter is FALSE, the server will perform the default processing for the command. If the ***bHandled*** parameter is set to TRUE, the server will take no action. Note that if the event handler processes the command, it must call the **SendResponse** method to send a success or error response back to the client. If this is not done, the server will consider the command to be invalid and will send a 501 "not implemented" error by default.

It is not necessary to use this event handler to disable a command. The **EnableCommand** method can be used to enable or disable specific commands, and the **IsCommandEnabled** method can be

used to determine if a command is enabled.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

DisconnectClient, EnableCommand, IsCommandEnabled, OnDisconnect, SendResponse

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CHttpServer::OnConnect Method

```
virtual void OnConnect(
   UINT nClientId,
   LPCTSTR lpszAddress
);
```

A virtual method that is invoked after the client has connected to the server.

Parameters

nClientId

An unsigned integer which uniquely identifies the client session.

lpszAddress

A null-terminated string that specifies the IP address of the client. This address may either be in IPv4 or IPv6 format, depending on how the server was configured and the address the client used to establish the connection.

Return Value

None.

Remarks

The **OnConnect** event handler is invoked after the client has connected to the server. To implement an event handler, the application should create a class derived from the **CHttpServer** class, and then override this method.

This event only occurs after the server has checked the active client limits and has accepted the connection. If the server was started with security enabled, the TLS handshake has been performed. If the server has been suspended, or the limit on the maximum number of client sessions has been exceeded, the server will terminate the client session prior to this event handler being invoked.

If this event handler is not implemented, the server will perform the default action of accepting the connection and waiting for the client to send a request for a document. To reject a connection, call the **DisconnectClient** method to terminate the client session.

Your server application should never make the assumption that for each **OnConnect** event there will be one command issued by the client. A client may issue multiple commands per session, and in some cases a client may send no commands to the server. If the client is using HTTP 1.0, connections will not be persistent. This means that the client will connect to the server, issue one command and then disconnect. For clients that use HTTP 1.1, multiple commands may be issued using a single connection. There is no guarantee that either the client or server will maintain a persistent connection, and either may request that the connection be closed after a command has completed.

If the client is a web browser, it is not unusual to see multiple, simultaneous connections being established with your server for a single request. Do not be concerned if you see multiple connections without any commands being issued. Browsers will do this to in anticipation of downloading additional assets (stylesheets, images, etc.) to improve performance and will typically close any unused connections after a few seconds. You may also see multiple requests for the file `/favicon.ico`. The browser will request this icon to display in the browser address bar and bookmarks. If the file does not exist, the browser ignores the error response from the server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

DisconnectClient, OnCommand, OnDisconnect,

CHttpServer::OnDisconnect Method

```
virtual void OnDisconnect(
   UINT nClientId
);
```

A virtual method that is invoked immediately before the client is disconnected from the server.

Parameters

nClientId

An unsigned integer which uniquely identifies the client session.

Return Value

None.

Remarks

The **OnDisconnect** event handler is invoked immediately before the client is disconnected from the server. To implement an event handler, the application should create a class derived from the **CHttpServer** class, and then override this method.

This is an advisory event and it is not required for the application to explicitly disconnect the client or perform any action. The event handler cannot prevent the client from disconnecting. Applications that implement a handler for this event should only use it to update any private data that was associated with the client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

See Also

OnConnect

CHttpServer::OnDownload Method

```
virtual void OnDownload(
   UINT nClientId,
   LPCTSTR lpszFileName,
   DWORD dwTimeElapsed,
   ULARGE_INTEGER uiBytesCopied
);
```

A virtual method that is invoked after the client has successfully downloaded a file from the server.

Parameters

nClientId

An unsigned integer which uniquely identifies the client session.

lpszFileName

A null-terminated string that specifies the local path name of the file that was downloaded from the server. The path will always include the disk volume or share name, and the path delimiter will always be the backslash character.

dwTimeElased

An unsigned integer value that specifies the number of milliseconds that it took to complete the file transfer.

uiBytesCopied

An unsigned 64-bit integer value that specifies the number of bytes of data that was downloaded by the client.

Return Value

None.

Remarks

The **OnDownload** event handler is invoked after the client has successfully downloaded a file from the server using the GET command. To implement an event handler, the application should create a class derived from the **CHttpServer** class, and then override this method.

The ULARGE_INTEGER structure is actually a union that is used to represent a 64-bit value. If the compiler has built-in support for 64-bit integers, use the **QuadPart** member to access the 64-bit integer value. Otherwise, use the **LowPart** and **HighPart** members to access the value.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

CHttpServer::OnError Method

```
virtual void OnConnect(
   UINT nClientId,
   UINT nEventId,
   DWORD dwError
);
```

A virtual method that is invoked when the event handler encountered an error when processing a client event.

Parameters

nClientId

An unsigned integer which uniquely identifies the client session.

nEventId

An unsigned integer which identifies the client event that was being processed when the error occurred. For a list of event identifiers, see Server Event Constants.

dwError

An unsigned integer value that specifies the error code.

Return Value

None.

Remarks

The **OnError** event handler is invoked whenever an error occurs while an event is being processed by the server. To implement an event handler, the application should create a class derived from the **CHttpServer** class, and then override this method.

It is important to note that this event is not raised for every error that occurs. The event only occurs when another event is being processed and an unhandled error occurs that must be reported back to the server application. The following are some common situations in which this event handler may be invoked:

- A network error occurs when the client connection is being accepted by the server. This could be the result of an aborted connection or some other lower-level failure reported by the networking subsystem on the server.
- The server is configured to use implicit TLS but cannot obtain the security credentials required to create the security context for the session. Usually this indicates that the server certificate cannot be found, or the certificate does not have a private key associated with it. It could also indicate a general problem with the cryptographic subsystem where the client and server could not successfully negotiate a cipher suite.
- A network error occurs when attempting to process a command issued by the client. This usually indicates that the connection to the client has been aborted, either because the client is not acknowledging the data that has been exchanged with the server, or the client has terminated abnormally. This event will not occur if the client terminates the connection normally.

In most situations where this event handler is invoked, the error is not recoverable and the only action that can be taken is to terminate the client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

See Also

GetLastError, OnConnect, OnCommand

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CHttpServer::OnExecute Method

```
virtual void OnExecute(
   UINT nClientId,
   LPCTSTR lpszCommand,
   LPCTSTR lpszResource,
   LPCTSTR lpszParameters,
   DWORD dwExitCode
);
```

A virtual method that is invoked after the client has successfully executed a CGI program or script on the server.

Parameters

nClientId

An unsigned integer which uniquely identifies the client session.

lpszCommand

A null-terminated string that specifies the command issued by the client. The command name will always be capitalized. For a complete list of commands supported by the server, see Server Commands.

lpszResource

A null-terminated string that specifies the resource that the client has requested.

lpszParameters

A null-terminated string that specifies any query parameters that have been provided by the client. The string will be empty if there were no query parameters included with the request. The query parameters in this string will be URL encoded.

dwExitCode

An unsigned integer that specifies the exit code that was returned by the program.

Return Value

None.

Remarks

The **OnExecute** event handler is invoked after the client has successfully executed an external CGI program or script. To implement an event handler, the application should create a class derived from the **CHttpServer** class, and then override this method.

External programs must be registered by the server application using the **RegisterProgram** method. To enable the use of scripts, the **RegisterHandler** method can be used to associate an executable program with a specific file extension.

The **GetProgramOutput** method can be used to obtain the unfiltered output from the external command, while the **GetProgramText** method will return filtered output from the program that contains only printable text characters.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

CHttpServer::OnResult Method

```
virtual void OnResult(
   UINT nClientId,
   LPCTSTR lpszCommand,
   LPCTSTR lpszResource,
   LPCTSTR lpszParameters,
   UINT nResultCode
);
```

A virtual method that is invoked after the server has processed a command issued by the client.

Parameters

nClientId

An unsigned integer which uniquely identifies the client session.

lpszCommand

A null-terminated string that specifies the command issued by the client. The command name will always be capitalized. For a complete list of commands supported by the server, see Server Commands.

lpszResource

A null-terminated string that specifies the resource that the client has requested. Depending on the command issued, it may be a document, a folder or an executable script.

lpszParameters

A null-terminated string that specifies any query parameters that have been provided by the client. The string will be empty if there were no query parameters included with the request. The query parameters in this string will be URL encoded.

nResultCode

An integer value that specifies the result code that was sent to the client.

Return Value

None.

Remarks

The **OnResult** event handler is invoked after the server has processed a command issued by the client. To implement an event handler, the application should create a class derived from the **CHttpServer** class, and then override this method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CHttpServer::OnTimeout Method

```
virtual void OnTimeout(
   UINT nClientId,
   UINT nIdleTime,
   UINT nElapsed
);
```

A virtual method that is invoked after the client has exceeded the maximum allowed idle time.

Parameters

nClientId

An unsigned integer which uniquely identifies the client session.

nIdleTime

An unsigned integer value that specifies the current idle timeout period for the client in seconds.

nElapsed

An unsigned integer value that specifies the number of seconds that the client has been idle.

Return Value

None.

Remarks

The **OnTimeout** event handler is invoked after the client has has exceeded the maximum allowed idle time. To implement an event handler, the application should create a class derived from the **CHttpServer** class, and then override this method.

This event handler will be invoked prior to the client being disconnected from the server. This event will never occur while the server is returning data to the client. The **SetClientIdleTime** method can be used to change or refresh the idle timeout period for the session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

See Also

CHttpServer::OnUpload Method

```
virtual void OnUpload(
   UINT nClientId,
   LPCTSTR lpszFileName,
   DWORD dwTimeElapsed,
   ULARGE_INTEGER uiBytesCopied
);
```

A virtual method that is invoked after the client has successfully uploaded a file to the server.

Parameters

nClientId

An unsigned integer which uniquely identifies the client session.

lpszFileName

A null-terminated string that specifies the local path name of the file that was uploaded to the server. The path will always include the disk volume or share name, and the path delimiter will always be the backslash character.

dwTimeElased

An unsigned integer value that specifies the number of milliseconds that it took to complete the file transfer.

uiBytesCopied

An unsigned 64-bit integer value that specifies the number of bytes of data that was uploaded by the client.

Return Value

None.

Remarks

The **OnUpload** event handler is invoked after the client has successfully uploaded a file to the server using the PUT command. To implement an event handler, the application should create a class derived from the **CHttpServer** class, and then override this method.

The ULARGE_INTEGER structure is actually a union that is used to represent a 64-bit value. If the compiler has built-in support for 64-bit integers, use the **QuadPart** member to access the 64-bit integer value. Otherwise, use the **LowPart** and **HighPart** members to access the value.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

CHttpServer Data Structures

- HTTPCLIENTCREDENTIALS
- HTTPREQUEST
- HTTPRESPONSE
- HTTPSERVERTRANSFER

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HTTPCLIENTCREDENTIALS

The **HTTPCLIENTCREDENTIALS** structure defines the credentials used to authenticate a specific user.

```
typedef struct _HTTPCLIENTCREDENTIALS
{
    DWORD dwSize;
    DWORD dwFlags;
    UINT  nAuthType;
    UINT  nHostPort;
    TCHAR szHostName[HTTP_MAXHOSTNAME];
    TCHAR szUserName[HTTP_MAXUSERNAME];
    TCHAR szPassword[HTTP_MAXPASSWORD];
} HTTPCLIENTCREDENTIALS, *LPHTTPCLIENTCREDENTIALS;
```

Members

dwSize

An unsigned integer value that specifies the size of the structure.

dwFlags

An unsigned integer value is reserved for future use. This value will always be zero.

nAuthType

An unsigned integer value that identifies the authentication method.

nHostPort

The server port number.

szHostName

A null-terminated string that specifies the server host name.

szUserName

A null-terminated string that specifies the user name.

szPassword

A null-terminated string that specifies the user password.

Remarks

When an instance of this structure is passed to the **GetClientCredentials** method, this member must be initialized to the size of the structure and all other members must be initialized with a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

GetClientCredentials

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HTTPREQUEST

The **HTTPREQUEST** structure provides information about the request made by the client.

```
typedef struct _HTTPREQUEST
{
    DWORD  dwSize;
    DWORD  dwFlags;
    DWORD  dwVersion;
    DWORD  dwAccess;
    DWORD  dwLength;
    DWORD  dwReserved;
    UINT   nHostId;
    UINT   nHostPort;
    LPCSTR lpszCommand;
    LPCSTR lpszHostName;
    LPCSTR lpszUserName;
    LPCSTR lpszPassword;
    LPCSTR lpszResource;
    LPCSTR lpszParameters;
    LPCSTR lpszDirectory;
    LPCSTR lpszPathInfo;
    LPCSTR lpszProgram;
    LPCSTR lpszScriptFile;
    LPCSTR lpszLocalFile;
    LPCSTR lpszMediaType;
} HTTPREQUEST, *LPHTTPREQUEST;
```

Members

dwSize

An unsigned integer value that specifies the size of the structure.

dwFlags

An unsigned integer value that provides additional information about the request. It may be one or more of the following values:

Value	Description
HTTP_REQUEST_FLAG_PROTECTED	The resource that the client has requested is protected. The client should only be permitted to access the resource if the client session has been authenticated.
HTTP_REQUEST_FLAG_PROGRAM	The resource that the client has requested is a CGI program or an executable script. The output from the program or script should be returned to the client in the response. If this flag is specified, the ***lpszProgram*** member of the structure specifies the name of the program that should be executed.
HTTP_REQUEST_FLAG_SCRIPT	The resource that the client has requested is an executable script. This flag is set when the request URL is mapped to a registered script handler. The ***lpszProgram*** member specifies the name of the program that is responsible for executing the script, and the ***lpszScriptFile*** parameter specifies the full

	path to the script itself.

dwVersion

An unsigned integer value that specifies the protocol version used. It may be one of the following values:

Value	Description
HTTP_VERSION_09	The client issued a GET command without specifying a protocol version.
HTTP_VERISON_10	The client issued a command that specified version 1.0 of the protocol.
HTTP_VERSION_11	The client issued a command that specified version 1.1 of the protocol.

dwAccess

An unsigned integer value that specifies the access permissions that were assigned to the resource. For a list of file access permissions, see User and File Access Constants.

dwLength

An unsigned integer value that will specify the number of bytes of request data provided by the client. If the client did not submit any data with the request, this member will have a value of zero.

dwReserved

An unsigned integer value that is reserved for future use.

nHostId

An integer value that identifies the virtual host that was specified by the client. This is based on the value of the Host request header included in the request. This value will be zero if a host name is not specified by the client, or does not match one of the virtual hosts that have been created.

nHostPort

An integer value that specifies the port number that the client used to establish the connection. This will be the same port number that was used when starting the server.

lpszCommand

A null-terminated string that specifies the command that was issued by the client. The command will always be in upper case. Refer to Hypertext Transfer Protocol Commands for a list of standard commands.

lpszHostName

A null-terminated string that identifies the hostname or IP address that the client used to establish the connection. This will typically correspond to the hostname assigned to the server, or to one of the virtual hosts that have been created.

lpszUserName

A null-terminated string that specifies the username provided with the request. This member is only set if the client has included authentication credentials as part of the request. If the client has not provided any credentials, this member will be NULL.

lpszPassword

A null-terminated string that specifies the password provided with the request. This member is only set if the client has included authentication credentials as part of the request. If the client has not provided any credentials, this member will be NULL.

lpszResource

A null-terminated string that specifies the URL path provided by the client.

lpszParameters

A null-terminated string that specifies any query parameters that were included in the request made by the client. If the URL did not include any query parameters, this member will be NULL.

lpszDirectory

A null-terminated string the specifies the full path to the root directory for the virtual host.

lpszPathInfo

A null-terminated string that specifies additional path information provided by the client when referencing an executable CGI program or script in the URL. For example, if a program is mapped to the virtual path "/orders/invoice" and the client requests "/orders/invoice/pdf/10001" this member will be the string "/pdf/10001". If there is no path information associated with the request, this member will be NULL.

lpszProgram

A null-terminated string that specifies the local path to the CGI program that should be executed to process the request made by the client. If this member is NULL, it indicates that the client has provided a URL that maps to a local file or directory.

lpszScriptFile

A null-terminated string that specifies the local path to the script file that will be executed by the handler. If this member is NULL, it indicates that the request URL was not mapped to registered script handler.

lpszLocalFile

A null-terminated string that specifies the local path to the directory or file name referenced by the URL. If the ***lpszPathInfo*** member is not NULL, then this member will point to a local file name based the path information appended to the root directory for the virtual host.

lpszMediaType

A null-terminated string that identifies the request data using the standard Internet media types defined in RFC 2046. It is used to designate the format for various types of content and has two parts, a primary and secondary media type separated by a forward slash. Common examples are "text/plain", "text/html" and "application/octet-stream". If the client did not submit any data with the request, this member will be NULL.

Remarks

This structure is used with the **ReceiveRequest** method and all members should be initialized to a value of zero, except for the ***dwSize*** member which should be initialized to size of the structure. Failure to properly initialize the structure will cause the method call to fail.

The value of the ***lpszLocalFile*** member depends on whether the client has requested a static document, or if the URL is mapped to a registered program or script handler. If the request is for a static document, then the ***dwFlags*** member will not have the HTTP_REQUEST_FLAG_PROGRAM bit flag set and the ***lpszLocalFile*** member will be the full path to the document. If the URL is mapped to a registered program or script, then the ***lpszLocalFile*** member will be the full path to the server root directory, If the request URL included additional path information, that will be appended to the root directory.

The value of the ***lpszScriptFile*** member is only defined if the ***dwFlags*** member has the HTTP_REQUEST_FLAG_SCRIPT bit flag set. This indicates that the request URL references a file that is an executable script with a handler that was registered using the **RegisterHandler** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

See Also

ReceiveRequest, SendResponse, HTTPRESPONSE

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HTTPRESPONSE

The **HTTPRESPONSE** structure provides additional information about the response to the client.

```
typedef struct _HTTPRESPONSE
{
    DWORD   dwSize;
    DWORD   dwFlags;
    DWORD   dwVersion;
    DWORD   dwReserved;
    UINT    nExpires;
    UINT    nResultCode;
    LPCTSTR lpszReason;
    LPCTSTR lpszMediaType;
} HTTPRESPONSE, *LPHTTPRESPONSE;
```

Members

dwSize

An unsigned integer value that specifies the size of the structure.

dwFlags

An unsigned integer value that specifies one or more response flags. This member is reserved for future use and should always have a value of zero.

dwVersion

An unsigned integer value that specifies the protocol version used. It may be one of the following values:

Value	Description
HTTP_VERSION_DEFAULT	The server should respond to the client using the same version specified in the request.
HTTP_VERISON_10	The server should respond to the client using version 1.0 of the protocol.
HTTP_VERSION_11	The server should respond to the client using version 1.1 of the protocol.

dwReserved

An unsigned integer value that is reserved for future use.

nExpires

An integer value that specifies the number of seconds until the client should consider any cached response data to be stale. If this value is zero, the default cache expiration time for the server will be used. The default cache expiration time is 7200 seconds (2 hours). The value of this structure member is ignored if the HTTP_RESPONSE_NOCACHE option is specified when the response is sent to the client.

nResultCode

An integer value that specifies the result code that should be sent in response to the client request. The result code is a three-digit number that indicates success or failure. For more information, refer to the **GetCommandResult** method.

lpszReason

A string that that describes the result code sent to the client. The description should be brief and

should not contain any formatting characters or HTML markup. This parameter may be NULL, in which case a default description of the result code will be used.

lpszMediaType

A string that specifies the Internet media type for the data that is being sent to the client as defined in RFC 2046. The format for the content type string consists of two parts, a primary and secondary media type separated by a forward slash. Common examples are "text/plain", "text/html" and "application/octet-stream". If this member is NULL, the library will attempt to automatically determine the appropriate media type.

Remarks

This structure is used with the **SendResponse** method and the ***dwSize*** member must be initialized to size of the structure. Failure to properly initialize the structure will cause the method call to fail.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

See Also

GetCommandResult, ReceiveRequest, SendResponse, HTTPREQUEST

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HTTPSERVERTRANSFER

The **HTTPSERVERTRANSFER** structure provides information about the last file transfer performed by a client.

```
typedef struct _HTTPSERVERTRANSFER
{
    DWORD          dwSize;
    DWORD          dwReserved;
    DWORD          dwFileAccess;
    DWORD          dwTimeElapsed;
    ULARGE_INTEGER uiBytesCopied;
    TCHAR          szFileName[MAX_PATH];
} HTTPSERVERTRANSFER, *LPHTTPSERVERTRANSFER;
```

Members

dwSize

An unsigned integer value that specifies the size of the structure.

dwReserved

An unsigned integer value that is reserved for future use. This value will always be zero.

dwFileAccess

An unsigned integer value that specifies the how the local file was accessed. It can be one of the following values:

Value	Description
HTTP_FILE_READ	The file was opened for reading. This mode indicates that the client issued the GET command to download the contents of a file from the server to the client system. The ***szFileName*** member specifies the name of the local file on the server that was downloaded by the client.
HTTP_FILE_WRITE	The file was opened for writing. This mode indicates that the client issued the PUT command to upload the contents of a file from the client system to server. The ***szFileName*** member specifies the name of the local file on the server that was created by the client. If a file already existed with the name name, it was replaced.

dwTimeElapsed

The amount of time that it took for the file transfer to complete in milliseconds. This value is limited to the resolution of the system timer, which is typically in the range of 10 to 16 milliseconds. This value may be zero if the transfer occurred over a local network or on the same host using a loopback address.

uiBytesCopied

A 64-bit integer value that specifies the total number of bytes copied during the file transfer. This value is represented by a ULARGE_INTEGER union which provides support for those programming languages that do not have intrinsic support for 64-bit integers. For more information, refer to the Windows SDK documentation. The application should not make the assumption that this is the actual size of the file.

szFileName

A null-terminated string value that will contain the full path to the local file that was transferred. The ***dwFileAccess*** member determines whether the file name represents a file that was downloaded by

the client, or uploaded from the client and stored on the server.

Remarks

When an instance of this structure is passed to the **GetTransferInfo** method, the ***dwSize*** member must be initialized to the size of the structure, otherwise the method will fail with an error indicating that the parameter is invalid. All other members should be initialized to a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

GetTransferInfo

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SECURITYCREDENTIALS

The **SECURITYCREDENTIALS** structure specifies the information needed by the library to specify the security protocol and server certificate when accepting a secure connection.

```
typedef struct _SECURITYCREDENTIALS
{
    DWORD    dwSize;
    DWORD    dwProtocol;
    DWORD    dwOptions;
    DWORD    dwReserved;
    LPCTSTR  lpszHostName;
    LPCTSTR  lpszUserName;
    LPCTSTR  lpszPassword;
    LPCTSTR  lpszCertStore;
    LPCTSTR  lpszCertName;
    LPCTSTR  lpszKeyFile;
} SECURITYCREDENTIALS, *LPSECURITYCREDENTIALS;
```

Members

dwSize

Size of this structure. If the structure is being allocated dynamically, this member must be set to the size of the structure and all other unused structure members must be initialized to a value of zero or NULL.

dwProtocol

A bitmask of supported security protocols. The value of this structure member is constructed by using a bitwise operator with any of the following values:

Value	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_TLS	Either the TLS 1.2 or 1.3 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers which reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing

	a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Value	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

dwReserved

This structure member is reserved for future use and should always be initialized to zero.

lpszHostName

A null-terminated string which specifies the hostname that will be used when validating the server certificate. If this member is NULL, then the server certificate will be validated against the hostname used to establish the connection.

lpszUserName

A null-terminated string which identifies the owner of client certificate. Currently this member is not used by the library and should always be initialized as a NULL pointer.

lpszPassword

A null-terminated string which specifies the password needed to access the certificate. Currently this member is only used if the CREDENTIAL_STORE_FILENAME option has been specified. If there is no password associated with the certificate, then this member should be initialized as a NULL pointer.

lpszCertStore

A null-terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A null-terminated string which specifies the name of the certificate to use. The library will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the library will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the library will return an error indicating that the certificate could not be found. If the SECURITY_PROTOCOL_SSH protocol has been specified, this member should be NULL.

lpszKeyFile

This member is not used and should always be NULL. The private key cannot be specified separately and must be associated with the certificate.

Remarks

A client application only needs to create this structure if the server requires that the client provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is

specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The ***dwOptions*** member should be set to CREDENTIAL_STORE_FILENAME and the ***lpszCertStore*** member should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS #12. These certificate files typically have an extension of .pfx or .p12. Note that if a password was specified when the certificate file was created, it must be provided in the ***lpszPassword*** member or the library will be unable to access the certificate.

Note that the ***lpszUserName*** and ***lpszPassword*** members are values which are used to access the certificate store or private key file. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Internet Control Message Protocol Class Library

Determine if a remote host is reachable and how packets of data are routed to that system.

Reference

- Class Methods
- Data Structures
- Error Codes

Library Information

Class Name	CIcmpClient
File Name	CSICMV12.DLL
Version	12.0.3024.1286
LibID	66D5E749-831F-40CF-9B36-77A849C6C0E5
Import Library	CSICMV12.LIB
Dependencies	None
Standards	RFC 792

Overview

The Internet Control Message Protocol (ICMP) is commonly used to determine if a remote host is reachable and how packets of data are routed to that system. Users are most familiar with this protocol as it is implemented in the ping and traceroute command line utilities. The ping command is used to check if a system is reachable and the amount of time that it takes for a packet of data to make a round trip from the local system, to the remote host and then back again. The traceroute command is used to trace the route that a packet of data takes from the local system to the remote host, and can be used to identify potential problems with overall throughput and latency. The library can be used to build in this type of functionality in your own applications, giving you the ability to send and receive ICMP echo datagrams in order to perform your own analysis.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). You should install all updates for your development tools and have the current Windows SDK installed. The minimum supported version of Visual Studio is Visual Studio 2010 with Service Pack 1 (SP1) installed. The SocketTools header files are designed to be compatible with all modern C/C++ compilers and we also provide function definitions for several additional languages such as Object Pascal and Visual Basic.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are deploying applications to Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. If you are deploying applications to Windows 8, you must have the 8.1 update installed. If you are targeting the Windows on ARM platform, the minimum required version is Windows 10 build 1709.

SocketTools includes support for both 64-bit and 32-bit Windows platforms. All current versions of Windows are 64-bit, and we include 32-bit x86 libraries to maintain compatibility with legacy development tools. SocketTools also provides native ARM64 libraries for systems running Windows on

ARM. Note that 32-bit applications on ARM use x86 emulation, and Microsoft no longer supports native 32-bit ARM (ARM32) applications. Embarcadero's C++Builder and Delphi compilers (as of version 12.3) do not support building native ARM64 applications for Windows. For developing applications targeting the Windows on ARM platform, we recommend using Visual Studio 2019 or later.

The import libraries included with SocketTools are provided in several different formats. The most commonly used format is COFF, which is available for x64, x86 and native ARM64 platforms. For compatibility with older Borland (Embarcadero) compilers, we also provide OMF libraries for x86 platforms and ELF libraries for x64 platforms. If you are using Visual Studio, you will want to use the standard COFF import libraries. Note that some languages may not require import libraries and will link to the exported functions in the DLL based on the function declaration itself.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Internet Control Message Protocol Class Methods

Class	Description
CIcmpClient	Constructor which initializes the current instance of the class
~CIcmpClient	Destructor which releases resources allocated by the class
Method	Description
AttachHandle	Attach the specified client handle to this instance of the class
AttachThread	Attach the specified client handle to another thread
Cancel	Cancel the current blocking operation
DetachHandle	Detach the handle for the current instance of this class
DisableEvents	Disable asynchronous event notification
DisableTrace	Disable logging of network-level calls to the trace log
Echo	Send one or more echo datagrams to the specified host
EnableEvents	Enable asynchronous event notification
EnableTrace	Enable logging of network function calls to a file
FormatAddress	Convert a numeric IP address to a string
FreezeEvents	Suspend or resume event handling by the calling process
GetErrorString	Return a description for the specified error code
GetFirstHost	Return the first host from the traceroute
GetHandle	Return the client handle used by this instance of the class
GetHostAddress	Return the current host IP address
GetHostName	Return the current host name
GetLastError	Return the last error code
GetNextHost	Return the next host from the traceroute
GetPacketSize	Return the ICMP datagram packet size
GetRecvCount	Return the number of packets received
GetSendCount	Return the number of packets sent
GetSequenceId	Return the current sequence identifier
GetTimeout	Return the number of milliseconds until an operation times out
GetTimeToLive	Return the current time-to-live for the ICMP datagram
GetTripTime	Return the current trip time statistics
IcmpEventProc	Callback method that processes events generated by the client
IsBlocking	Determine if the client is blocked, waiting for information
IsInitialized	Determine if the class has been successfully initialized

RecvEcho	Read an ICMP datagram returned by the remote host
RegisterEvent	Register an event callback function
Reset	Reset the current client state
ResolveAddress	Resolve an IP address into a fully qualified host name
SendEcho	Send an ICMP datagram to the specified host
SetHostAddress	Set the IP address of the host to receive the next datagram
SetHostName	Set the name of the host to receive the next datagram
SetLastError	Set the last error code
SetPacketSize	Set the ICMP datagram packet size
SetSequenceId	Set the sequence identifier for the next datagram
SetTimeout	Set the number of milliseconds until an operation times out
SetTimeToLive	Set the time-to-live for the next datagram
ShowError	Display a message box with a description of the specified error
TraceRoute	Trace the route from the local system to a remote host

CIcmpClient::CIcmpClient Method

```
CIcmpClient();
```

The **CIcmpClient** constructor initializes the class library and validates the license key at runtime.

Remarks

If the constructor fails to validate the runtime license, subsequent methods in this class will fail. If the product is installed with an evaluation license, then the application will only function on the development system and cannot be redistributed.

The constructor calls the **IcmpInitialize** function to initialize the library, which dynamically loads other system libraries and allocates thread local storage. If you are using this class within another DLL, it is important that you do not create or destroy an instance of the class from within the **DllMain** function because it can result in deadlocks or access violation errors. You should not declare static or global instances of this class within another DLL if it is linked with the C runtime library (CRT) because it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

~CIcmpClient, IsInitialized

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CIcmpClient::~CIcmpClient

```
~CIcmpClient();
```

The **CIcmpClient** destructor releases resources allocated by the current instance of the **CIcmpClient** object. It also uninitializes the library if there are no other concurrent uses of the class.

Remarks

When a **CIcmpClient** object goes out of scope, the destructor is automatically called to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all handles that were created for the client session are destroyed.

The destructor is not called explicitly by the application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CIcmpClient

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CIcmpClient::AttachHandle Method

```
VOID AttachHandle(
   HCLIENT hClient
);
```

The **AttachHandle** method attaches the specified client handle to the current instance of the class.

Parameters

hClient

The handle to the client session that will be attached to the current instance of the class object.

Return Value

None.

Remarks

This method is used to attach a client handle created outside of the class using the SocketTools API. Once the client handle is attached to the class, the other class member functions may be used with that client session.

If a client handle has already been created for the class, that handle will be released when the new handle is attached to the class object. If you want to prevent the previous client session from being terminated, you must call the **DetachHandle** method. Failure to release the detached handle may result in a resource leak in your application.

Note that the ***hClient*** parameter is presumed to be a valid client handle and no checks are performed to ensure that the handle is valid. Specifying an invalid client handle will cause subsequent method calls to fail.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

See Also

AttachThread, DetachHandle, GetHandle

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CIcmpClient::AttachThread Method

```
DWORD AttachThread(
   DWORD dwThreadId
);
```

The **AttachThread** method attaches the specified client handle to another thread.

Parameters

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the method succeeds, the return value is the thread ID of the previous owner. If the method fails, the return value is ICMP_ERROR. To get extended error information, call **GetLastError**.

Remarks

When a client handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in a client application to create the client handle, and then pass that handle to another worker thread. The **AttachThread** method can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the method, the original owner of the handle can be restored before the worker thread terminates.

This method should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **AttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **Cancel** method and then release the handle after the blocking method exits and control is returned to the current thread.

Note that the ***dwThreadId*** parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the client handle used by the class until the destructor is called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

See Also

AttachHandle, Cancel, CloseHandle, CreateHandle, DetachHandle, GetHandle

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CIcmpClient::Cancel Method

```
INT Cancel();
```

The **Cancel** method cancels any outstanding blocking operation in the client, causing the blocking method to fail. The application may then retry the operation or terminate the client session.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is ICMP_ERROR. To get extended error information, call **GetLastError**.

Remarks

When the **Cancel** method is called, the blocking method will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

See Also

IsBlocking

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CIcmpClient::CloseHandle Method

```
INT CloseHandle(
   HCLIENT hClient
);
```

The **CloseHandle** method closes the socket and releases the memory allocated for the client session.

Parameters

hClient

A handle to the client session.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is ICMP_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib
Unicode: Implemented as Unicode and ANSI versions

CIcmpClient, CreateHandle

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CIcmpClient::CreateHandle Method

```
HCLIENT CreateHandle(
   UINT nPacketSize,
   UINT nTimeToLive,
   DWORD dwTimeout,
   DWORD dwReserved,
   HWND hEventWnd,
   UINT uEventMsg
);
```

The **CreateHandle** method creates a client handle for sending and receiving ICMP echo datagrams. If an event notification window is specified, the client will be notified when a network event occurs.

Parameters

nPacketSize

An unsigned integer which specifies the default packet size used when generating ICMP echo datagrams. The minimum packet size is 32 bytes and the maximum size is 65,535 bytes.

nTimeToLive

An unsigned integer which specifies the default time-to-live for ICMP echo datagrams. This determines the maximum number of times that a packet will be routed from one system to another while en route to its destination. The minimum time-to-live value is 1, the maximum is 255. The recommend value for this parameter is 255, and typical applications should use a time-to-live value of at least 30.

dwTimeout

An unsigned integer which specifies the maximum number of milliseconds to wait before the current operation times out.

dwReserved

A reserved parameter. This value should always be zero.

hEventWnd

The handle to an asynchronous notification window. This window receives messages which notify the client when asynchronous network events occur. If asynchronous event notification is not required, this parameter may be NULL.

uEventMsg

The message identifier that is used when an asynchronous network event occurs. This value should be greater than WM_USER as defined in the Windows header files. If the ***hEventWnd*** parameter is NULL, this parameter should be specified as WM_NULL.

Return Value

If the method succeeds, the return value is a handle to the client session. If the method fails, the return value is INVALID_CLIENT. To get extended error information, call **GetLastError**.

Remarks

The **CreateHandle** method creates a client handle that is used with subsequent calls to the library. This library uses a special type of socket called a raw socket, which is created to send and receive ICMP echo datagrams. Raw socket support is optional under the Windows Sockets specification, and may not be available if a non-standard networking libraries are used or may only be available to privileged accounts.

If the *hEventWnd* parameter is not NULL, the client operates in asynchronous mode and messages will be posted to the notification window when a network event occurs. When a message is posted to the window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has occurred. The *wParam* parameter contains the client handle. One or more of the following event identifiers may be sent:

Value	Description
ICMP_EVENT_ECHO	The client has generated an ICMP echo datagram and has sent it to the specified host. If the datagram is received, the remote host should generate a reply and return it to the sender.
ICMP_EVENT_REPLY	The client has received an ICMP echo reply datagram from the remote host. At this point the client can collect statistical information.
ICMP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation.
ICMP_EVENT_CANCEL	The current operation has been canceled. TThe client application may attempt to retry the operation or close the handle.

To cancel asynchronous notification and return the client to a blocking mode, use the **DisableEvents** method.

The ability to create and send ICMP echo datagrams is limited to privileged users. Non-administrator users will receive an error if they attempt to create a client handle. On Windows NT it is possible to disable this security check by creating or modifying the system registry. Microsoft Knowledge Base article 195445 has additional information and instructions for making this change.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Sockets 2.0 update or later.
Header File: cstools12.h
Import Library: csicmv12.lib

See Also

CIcmpClient, CloseHandle

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CIcmpClient::DetachHandle Method

```
HCLIENT DetachHandle();
```

The **DetachHandle** method detaches the client handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the client handle associated with the current instance of the class object. If there is no active client session, the value INVALID_CLIENT will be returned.

Remarks

This method is used to detach a client handle created by the class for use with the SocketTools API. Once the client handle is detached from the class, no other class member functions may be called. Note that the handle must be explicitly released at some later point by the process or a resource leak will occur.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

See Also

AttachHandle, GetHandle

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CIcmpClient::DisableEvents Method

```
INT DisableEvents();
```

The **DisableEvents** method disables the event notification mechanism, preventing subsequent event notification messages from being posted to the application's message queue.

This method has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is ICMP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **DisableEvents** method is used to disable event message posting for the specified client session. Although this will immediately prevent any new events from being generated, it is possible that messages could be waiting in the message queue. Therefore, an application must be prepared to handle client event messages after this method has been called.

This method is automatically called if the client has event notification enabled, and the **Disconnect** method is called. The same issues regarding outstanding event messages also applies in this situation, requiring that the application handle event messages that may reference a client handle that is no longer valid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

See Also

EnableEvents, RegisterEvent

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CIcmpClient::DisableTrace Method

```
BOOL DisableTrace();
```

The **DisableTrace** method disables the logging of network function calls.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, a value of zero is returned.

Remarks

This method will disable output to the log file for the current thread or process, depending on the flags used when logging was enabled. If this method is not called, the resources that were allocated for the logging session will be released when the process ends.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

See Also

EnableTrace

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CIcmpClient::Echo Method

```
INT Echo(
   LPCTSTR lpszHostName,
   UINT nIterations,
   UINT nPacketSize,
   DWORD dwTimeout,
   LPICMPTIME lpTime
);

INT Echo(
   LPCTSTR lpszHostName,
   LPICMPTIME lpTime
);
```

The **Echo** method sends one or more ICMP echo datagrams, collecting information about the reliability and latency of a connection between the local and remote host.

Parameters

lpszHostName

A null-terminated string which specifies the fully qualified domain name of the remote host, or the IP address in dotted notation.

nIterations

An unsigned integer value which specifies the number of echo datagrams that will be sent to the remote host. The minimum value for this parameter is 1 and the maximum value is 512.

nPacketSize

An unsigned integer value which specifies the size of the echo datagram in bytes. The minimum size is 1 byte and the maximum size is 65,535 bytes. It is recommended that most applications use the minimum size of 32 bytes for this parameter.

dwTimeout

An unsigned integer which specifies the number of milliseconds the method will wait for a response to an echo datagram.

lpTime

A pointer to an ICMPTIME structure which will contain the minimum, maximum and average round trip times for the echo datagrams sent and received.

Return Value

If the method succeeds, the return value is the number of replies received from the remote host. If the method fails, the return value is ICMP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **Echo** method sends a series of ICMP echo datagrams to the specified host, providing a simplified interface for pinging a remote system. If the method returns the same value as the number of iterations, then replies were received for all of the echo datagrams that were sent. This would typically indicate that the client can establish a reliable connection to the server; the values returned in the ICMPTIME structure provide information on the latency between the two hosts. Higher average time values would indicate greater latency and reduced throughput between the systems. If the method returns a value less than the specified number of iterations, this indicates that replies were not received for one or more of the echo datagrams. This may indicate that there are problems routing

data between the local and remote host. A return value of zero indicates that there was no response to the echo datagrams. The remote host may not exist or may not be available.

The failure for a host to respond to an ICMP echo datagram may not indicate a problem with the remote system. In some cases, a router between the local and remote host may be malfunctioning or discarding the datagrams. Systems can also be configured to specifically ignore ICMP echo datagrams and not respond to them; this is often a security measure to prevent certain kinds of Denial of Service attacks.

The ability to send ICMP datagrams may be restricted to users with administrative privileges, depending on the policies and configuration of the local system. If you are unable to send or receive any ICMP datagrams, it is recommended that you check the firewall settings and any third-party security software that could impact the normal operation of this component.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

See Also

CreateHandle, GetTripTime, RecvEcho, SendEcho, TraceRoute

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CIcmpClient::EnableEvents Method

```
INT EnableEvents(
   HWND hEventWnd,
   UINT uEventMsg
);
```

The **EnableEvents** method enables event notifications using Windows messages.

This method has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Applications should use the **RegisterEvent** method to register an event handler which is invoked when an event occurs.

Parameters

hEventWnd

Handle to the window which will receive the client notification messages. This parameter must specify a valid window handle. If a NULL handle is specified, event notification will be disabled.

uEventMsg

The message that is received when a client event occurs. This value must be greater than 1024.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is ICMP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **EnableEvents** method is used to request that notification messages be posted to the specified window whenever a client event occurs. This allows an application to monitor the status of different client operations, such as a file transfer.

The *wParam* argument will contain the client handle, the low word of the *lParam* argument will contain the event ID, and the high word will contain any error code. If no error has occurred, the high word will always have a value of zero. The following events may be generated:

Value	Description
ICMP_EVENT_ECHO	The client has generated an ICMP echo datagram and has sent it to the specified host. If the datagram is received, the remote host should generate a reply and return it to the sender.
ICMP_EVENT_REPLY	The client has received an ICMP echo reply datagram from the remote host. At this point the client can collect statistical information.
ICMP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
ICMP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

To disable event notification, call the **DisableEvents** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

CIcmpClient::EnableTrace Method

```
BOOL EnableTrace(
   LPCTSTR lpszTraceFile,
   DWORD dwTraceFlags
);
```

The **EnableTrace** method enables the logging of network function calls to a file.

Parameters

lpszTraceFile

A null-terminated string which specifies the name of the logfile which will be appended to or created. It is recommended that this file always specify an absolute path to avoid any ambiguity. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
TRACE_INFO	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
TRACE_ERROR	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
TRACE_HEXDUMP	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
TRACE_TRUNCATE	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for

	multithreaded applications that are using worker threads.

Return Value

If the method succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the log file cannot be created.

Remarks

Logging is enabled and disabled at the thread or process level, depending on the flags passed to this method, and is not associated with a specific class instance. When logging is enabled, the information is appended to the specified file. If the file does not exist, it will be created. To limit the size of the file, enable and disable logging only around those sections of code that you wish to debug. If you do not provide a full path to the file, it will be relative to the current working directory for the process. This can produce unexpected results in multithreaded applications because the current directory is global to the entire process and can be changed by any thread at any time.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

The TRACE_HEXDUMP option can generate very large files because it includes all of the data exchanged between your application and the remote host. The TRACE_TRUNCATE option is only evaluated when logging is first enabled for a thread or process. If logging is already active, specifying this option will have no effect.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "**0x**". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxxx:xxxx::xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, a connection is being made to a system with the IPv4 address 192.0.0.1 on port 1234.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib
Unicode: Implemented as Unicode and ANSI versions

CIcmpClient::FormatAddress Method

```
INT FormatAddress(
   DWORD dwAddress,
   LPTSTR lpszAddress,
   INT nMaxLength
);

INT FormatAddress(
   DWORD dwAddress,
   CString& strAddress
);
```

The **FormatAddress** method converts a numeric IP address to a null-terminated string.

Parameters

dwAddress

A unsigned 32-bit integer which specifies the IP address to be converted into a string.

lpszAddress

A null-terminated string which will contain the converted IP address in dot-notation. This string should be at least 16 characters in length. An alternate form of this method accepts a **CString** object which will contain the IP address in dotted notation when the method returns.

nMaxLength

The maximum number of characters which may be copied in to the string buffer.

Return Value

If the method succeeds, the return value is the length of the string buffer. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetHostAddress, GetHostName, ResolveAddress

CIcmpClient::FreezeEvents Method

```
INT FreezeEvents(
   BOOL bFreeze
);
```

The **FreezeEvents** method is used to suspend and resume event handling by the client.

Parameters

bFreeze

A non-zero value specifies that event handling should be suspended by the client. A zero value specifies that event handling should be resumed.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is ICMP_ERROR. To get extended error information, call **GetLastError**.

Remarks

This method should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all client events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if the client has suspended event handling, and four read events occur, once event handling is resumed only one of those read events will be posted to the client. This prevents the application from being flooded by a potentially large number of queued events.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib
Unicode: Implemented as Unicode and ANSI versions

CIcmpClient::GetErrorString Method

```
INT GetErrorString(
   DWORD dwErrorCode,
   LPTSTR lpszDescription,
   INT nMaxLength
);

INT GetErrorString(
   DWORD dwErrorCode,
   CString& strDescription
);
```

The **GetErrorString** method is used to return a description of a specific error code. Typically this is used in conjunction with the **GetLastError** method for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

The buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length. An alternate form of the method accepts a **CString** variable which will contain the error description.

nMaxLength

The maximum number of characters that may be copied into the description buffer.

Return Value

If the method succeeds, the return value is the length of the description string. If the method fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the method is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib
Unicode: Implemented as Unicode and ANSI versions

CIcmpClient::GetFirstHost Method

```
BOOL GetFirstHost(
   ICMPTRACE& icmpTrace
);
```

The **GetFirstHost** method returns information about the first host between the local system and the remote host specified in the call to the **TraceRoute** method.

Parameters

icmpTrace

An ICMPTRACE structure which contains information about the intermediate host.

Return Value

If the method succeeds, the return value is non-zero. If the return value is zero, this indicates that no host information is available. To get extended error information, call **GetLastError**.

Remarks

The **GetFirstHost** method is used in conjunction with the **GetNextHost** method to enumerate all of the intermediate hosts between the local system and the remote host specified when the **TraceRoute** method was called.

Example

```
BOOL bResult = pClient->TraceRoute(strAddress);
if (bResult)
{
    ICMPTRACE icmpTrace;

    bResult = pClient->GetFirstHost(icmpTrace);
    while (bResult)
    {
        // The icmpTrace structure contains information about the
        // intermediate host in the traceroute
        CString strHostName;
        pClient->ResolveAddress(icmpTrace.dwHostAddress, strHostName);

        bResult = pClient->GetNextHost(icmpTrace);
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CIcmpClient::GetHandle Method

```
HCLIENT GetHandle();
```

The **GetHandle** method returns the client handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the client handle associated with the current instance of the class object. If there is no active client session, the value INVALID_CLIENT will be returned.

Remarks

This method is used to obtain the client handle created by the class for use with the SocketTools API.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

See Also

CIcmpClient::GetHostAddress Method

```
INT GetHostAddress(
   LPTSTR lpszHostAddress,
   INT cbHostAddress
);

INT GetHostAddress(
   CString& strHostAddress
);
```

The **GetHostAddress** copies the IP address of the current host into the specified buffer as a string using dot-notation.

Parameters

lpszHostAddress

The buffer that will contain the IP address of the current remote host in dot-notation. This buffer should be at least 16 characters in length.

cbHostAddress

The maximum number of characters that may be copied into the buffer, including the terminating null character character.

Return Value

If the method succeeds, the return value is the length of the address string. If the return value is zero, this indicates that no remote host has been specified. If the method fails, the return value is ICMP_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

FormatAddress, GetHostName, ResolveAddress, SetHostAddress, SetHostName

CIcmpClient::GetHostName Method

```
INT GetHostName(
   LPTSTR lpszHostName,
   INT cbHostName
);

INT GetHostName(
   CString& strHostName
);
```

The **GetHostName** copies the name of the current host into the specified buffer.

Parameters

lpszHostName

The buffer that will contain the name of the current remote host. This buffer should be at least 64 characters in length.

cbHostName

The maximum number of characters that may be copied into the buffer, including the terminating null character character.

Return Value

If the method succeeds, the return value is the length of the host name string. If the return value is zero, this indicates that no remote host has been specified. If the method fails, the return value is ICMP_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CIcmpClient::GetLastError Method

```
DWORD GetLastError();

DWORD GetLastError(
   CString& strDescription
);
```

Parameters

strDescription

A string which will contain a description of the last error code value when the method returns. If no error has been set, or the last error code has been cleared, this string will be empty.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **SetLastError** method. The Return Value section of each reference page notes the conditions under which the method sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **GetLastError** method immediately when a method's return value indicates that an error has occurred. That is because some methods call **SetLastError**(0) when they succeed, clearing the error code set by the most recently failed method.

Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or ICMP_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

The description of the error code is the same string that is returned by the **GetErrorString** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

See Also

GetErrorString, SetLastError, ShowError

CIcmpClient::GetNextHost Method

```
BOOL GetFirstHost(
   ICMPTRACE& icmpTrace
);
```

The **GetNextHost** method returns information about the next host between the local system and the remote host specified in the call to the **TraceRoute** method.

Parameters

icmpTrace

An ICMPTRACE structure which contains information about the intermediate host.

Return Value

If the method succeeds, the return value is non-zero. If the return value is zero, this indicates that no host information is available. To get extended error information, call **GetLastError**.

Remarks

The **GetNextHost** method is used in conjunction with the **GetFirstHost** method to enumerate all of the intermediate hosts between the local system and the remote host specified when the **TraceRoute** method was called.

Example

```
BOOL bResult = pClient->TraceRoute(strAddress);
if (bResult)
{
    ICMPTRACE icmpTrace;

    bResult = pClient->GetFirstHost(icmpTrace);
    while (bResult)
    {
        // The icmpTrace structure contains information about the
        // intermediate host in the traceroute
        CString strHostName;
        pClient->ResolveAddress(icmpTrace.dwHostAddress, strHostName);

        bResult = pClient->GetNextHost(icmpTrace);
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetFirstHost, ResolveAddress, TraceRoute

CIcmpClient::GetPacketSize Method

```
UINT GetPacketSize();
```

The **GetPacketSize** method returns the size of the ICMP echo datagram that will be sent to the remote host. The minimum packet size is 1 byte, the maximum packet size is 65,535 bytes.

Parameters

None.

Return Value

If the method succeeds, the return value is the size of the datagram. If the method fails, the return value is ICMP_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CIcmpClient::GetRecvCount Method

```
INT GetRecvCount();
```

The **GetRecvCount** method returns the number of replies sent to the client from the remote host.

Parameters

None.

Return Value

If the method succeeds, the return value is the number of replies. If the method fails, the return value is ICMP_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetPacketSize, GetSendCount, GetSequenceId, GetTimeToLive, GetTripTime, SetSequenceId, SetTimeToLive

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CIcmpClient::GetSendCount Method

```
INT GetSendCount();
```

The **GetSendCount** method returns the number of datagrams sent to the remote host by the client.

Parameters

None.

Return Value

If the method succeeds, the return value is the number of datagrams sent by the client. If the method fails, the return value is ICMP_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetPacketSize, GetRecvCount, GetSequenceId, GetTimeToLive, GetTripTime, SetSequenceId, SetTimeToLive

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CIcmpClient::GetSequenceId Method

```
INT GetSequenceId();
```

The **GetSequenceId** method returns the sequence identifier for the last ICMP echo datagram received by the client.

Parameters

None.

Return Value

If the method succeeds, the return value is the sequence identifier. If the method fails, the return value is ICMP_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetPacketSize, GetRecvCount, GetSendCount, GetTimeToLive, GetTripTime, SetSequenceId, SetTimeToLive

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CIcmpClient::GetTimeout Method

```
INT GetTimeout();
```

The **GetTimeout** method returns the number of seconds the client will wait for a response from the remote host. Once the specified number of seconds has elapsed, the method will fail and return to the caller.

Parameters

None.

Return Value

If the method succeeds, the return value is the timeout period in seconds. If the method fails, the return value is ICMP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The timeout value is only used with blocking client connections. A value of zero indicates that the default timeout period of 20 seconds should be used.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

See Also

CreateHandle, SetTimeout

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CIcmpClient::GetTimeToLive Method

```
INT GetTimeToLive();
```

The **GetTimeToLive** method returns the time-to-live for the last ICMP echo datagram received by the client.

Parameters

None.

Return Value

If the method succeeds, the return value is the time-to-live for the last datagram. If the method fails, the return value is ICMP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The time-to-live (TTL) value is specified in the IP header of a datagram, and is used to control the number of routers that the datagram is passed through. Each router that handles the datagram decrements the TTL value by one. When it drops to zero, a datagram is returned to the sender, specifying that the TTL has been exceeded. The default value is 255.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

See Also

GetPacketSize, GetRecvCount, GetSendCount, GetSequenceId, GetTripTime, SetSequenceId, SetTimeToLive

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CIcmpClient::GetTripTime Method

```
INT GetTripTime(
   LPICMPTIME lpTime
);
```

The **GetTripTime** returns round-trip statistics for the datagrams sent to the current remote host.

Parameters

lpTime

A pointer to an ICMPTIME data structure which will contain the round-trip statistics for the current remote host.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is ICMP_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

See Also

GetPacketSize, GetRecvCount, GetSendCount, GetSequenceId, GetTimeToLive, SetSequenceId, SetTimeToLive

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CIcmpClient::IsBlocking Method

```
BOOL IsBlocking();
```

The **IsBlocking** method is used to determine if the client is currently performing a blocking operation.

Parameters

None.

Return Value

If the client is performing a blocking operation, the method returns a non-zero value. If the client is not performing a blocking operation, or the client handle is invalid, the method returns zero.

Remarks

Because a blocking operation can allow the application to be re-entered (for example, by pressing a button while the operation is being performed), it is possible that another blocking method may be called while it is in progress. Since only one thread of execution may perform a blocking operation at any one time, an error would occur. The **IsBlocking** method can be used to determine if the client is already blocked, and if so, take some other action (such as warning the user that they must wait for the operation to complete).

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

Cancel, IsInitialized

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CIcmpClient::IsInitialized Method

```
BOOL IsInitialized();
```

The **IsInitialized** method returns whether or not the class object has been successfully initialized.

Return Value

This method returns a non-zero value if the class object has been successfully initialized. A return value of zero indicates that the runtime license key could not be validated or the networking library could not be loaded by the current process.

Remarks

When an instance of the class is created, the class constructor will attempt to initialize the component with the runtime license key that was created when SocketTools was installed. If the constructor is unable to validate the license key or load the networking libraries, this initialization will fail.

If SocketTools was installed with an evaluation license, the application cannot be redistributed to another system. The class object will fail to initialize if the application is executed on another system, or if the evaluation period has expired. To redistribute your application, you must purchase a development license which will include the runtime key that is needed to redistribute your software to other systems. Refer to the Developer's Guide for more information.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

See Also

CIcmpClient, IsBlocking

CIcmpClient::RecvEcho Method

```
INT RecvEcho();
```

The **RecvEcho** method reads the reply to an ICMP echo datagram generated by the client. This method should only be called by asynchronous client sessions in response to an event notification that a datagram has been received.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is ICMP_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

See Also

GetRecvCount, GetSequenceId, GetTimeToLive, SendEcho

CIcmpClient::RegisterEvent Method

```
INT RegisterEvent(
   UINT nEventId,
   ICMPEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

The **RegisterEvent** method registers an event handler for the specified event.

Parameters

nEventId

An unsigned integer which specifies which event should be registered with the specified callback function. One of the following values may be used:

Value	Description
ICMP_EVENT_ECHO	The client has generated an ICMP echo datagram and has sent it to the specified host. If the datagram is received, the remote host should generate a reply and return it to the sender.
ICMP_EVENT_REPLY	The client has received an ICMP echo reply datagram from the remote host. At this point the client can collect statistical information.
ICMP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
ICMP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **IcmpEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Remarks

The **RegisterEvent** method associates a callback function with a specific event. The event handler is an **IcmpEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

The callback function specified by the ***lpEventProc*** parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

The *dwParam* parameter is commonly used to identify the class instance which is associated with the event that has occurred. Applications will cast the **this** pointer to a DWORD_PTR value when calling this function, and then the event handler will cast it back to a pointer to the class instance. This gives the handler access to the class member variables and methods.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is ICMP_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

See Also

DisableEvents, EnableEvents, FreezeEvents, IcmpEventProc

CIcmpClient::Reset Method

```
INT Reset();
```

The **Reset** method resets the client session, clearing the packet trip statistics, time-to-live, sequence identifier, send and receive counts.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is ICMP_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

See Also

SetHostAddress, SetHostName, SetSequenceId, SetTimeToLive

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CIcmpClient::ResolveAddress Method

```
INT ResolveAddress(
   DWORD dwAddress,
   LPTSTR lpszHostName,
   INT nMaxLength
);

INT ResolveAddress(
   DWORD dwAddress,
   CString& strHostName
);
```

The **ResolveAddress** method resolves a numeric IP address into a fully qualified domain name.

Parameters

dwAddress

The IP address to be resolved, specified as an unsigned 32-bit integer in network byte order.

lpszHostName

A buffer that will contain a null-terminated string that specifies the fully qualified domain name for the host. It is recommended that this buffer be at least 64 characters in length.

nMaxLength

The maximum number of characters that can be copied into the string buffer, including the terminating null character.

Return Value

If the method succeeds, the return value is the length of the host name. If the method fails, the return value is ICMP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **ResolveAddress** method is used to perform a reverse DNS lookup, converting a numeric IP address into a fully qualified domain name. This is useful for methods like **TraceRoute**, which return host addresses as numeric values in network byte order. If the reverse DNS lookup fails because there is no PTR record for the given IP address, a printable form of the address in dotted notation will be returned in the string buffer.

Calling this method will cause the thread to block until the IP address is resolved, or until the DNS query times out because there is no reverse record for the address. In some cases, a reverse lookup can take several seconds.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

See Also

GetHostAddress, GetHostName, SetHostAddress, SetHostName, TraceRoute

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CIcmpClient::SendEcho Method

```
INT SendEcho();
```

The **SendEcho** method sends an ICMP echo datagram to the remote host.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is ICMP_ERROR. To get extended error information, call **GetLastError**.

Remarks

For asynchronous client sessions, this method returns immediately. Otherwise, the client enters a blocking state and waits for a reply from the remote host. The method returns when a reply has been received, or the operation times-out.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

Echo, GetSendCount, RecvEcho, SetSequenceId, SetTimeToLive, TraceRoute

CIcmpClient::SetHostAddress Method

```
INT SetHostAddress(
   DWORD dwAddress
);

INT SetHostAddress(
   LPCTSTR lpszAddress
);
```

The **SetHostAddress** method specifies the IP address of the host to receive an ICMP echo datagram. If the address specifies a new host, the current client statistics are reset.

Parameters

dwAddress

The IP address of the remote host as a 32-bit integer value, specified in network byte order. In an alternate form of this method, a pointer to a string which specifies the IP address in dotted notation may also be used.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is ICMP_ERROR. To get extended error information, call **GetLastError**.

Remarks

To specify a remote host name, use the **SetHostName** method instead.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

See Also

GetHostAddress, GetHostName, SetHostName

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CIcmpClient::SetHostName Method

```
INT SetHostName(
   HCLIENT hClient,
   LPCTSTR lpszHostName
);
```

The **SetHostName** method specifies the name of the host to receive an ICMP echo datagram. If the name specifies a new host, the current client statistics are reset.

Parameters

hClient

A handle to the client session.

lpszHostName

A null-terminated string which specifies the name, or IP address in dot-notation, of the remote host.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is ICMP_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetHostAddress, GetHostName, SetHostAddress

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CIcmpClient::SetLastError Method

```
VOID SetLastError(
   DWORD dwErrorCode
);
```

The **SetLastError** method sets the last error code for the current thread. This method is typically used to clear the last error by specifying a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or ICMP_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

Applications can retrieve the value saved by this method by using the **GetLastError** method. The use of **GetLastError** is optional; an application can call the method to determine the specific reason for a method failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

See Also

GetErrorString, GetLastError, ShowError

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CIcmpClient::SetPacketSize Method

```
UINT SetPacketSize(
   UINT nPacketSize
);
```

The **SetPacketSize** method sets the size of the ICMP datagram packet that is sent to the remote host.

Parameters

nPacketSize

Size of the ICMP datagram packet in bytes. The minimum packet size is 1 byte and the maximum packet size is 65,535 bytes.

Return Value

If the method succeeds, the return value is the previous ICMP datagram packet size. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

Note that packet sizes over 512 bytes may not be supported by your networking software or configuration. It is recommended that most applications use the minimum packet size of 32 bytes.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

See Also

GetPacketSize, SetSequenceId, SetTimeToLive

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CIcmpClient::SetSequenceId Method

```
INT SetSequenceId(
   INT nSequenceId
);
```

The **SetSequenceId** method sets the sequence identifier for the next ICMP echo datagram sent by the client. The default sequence identifier for the first datagram is one.

Parameters

nSequenceId

The sequence identifier for the next datagram sent by the client.

Return Value

If the method succeeds, the return value is the previous sequence identifier. If the method fails, the return value is ICMP_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

See Also

GetPacketSize, GetRecvCount, GetSendCount, GetSequenceId, GetTimeToLive, GetTripTime, SetPacketSize, SetTimeToLive

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CIcmpClient::SetTimeout Method

```
INT SetTimeout(
   UINT nTimeout
);
```

The **SetTimeout** method sets the number of seconds the client will wait for a response from the remote host. Once the specified number of seconds has elapsed, the method will fail and return to the caller.

Parameters

nTimeout

The number of seconds to wait for a blocking operation to complete.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is ICMP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The timeout value is only used with blocking client connections.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

See Also

GetTimeout

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CIcmpClient::SetTimeToLive Method

```
INT SetTimeToLive(
   INT nTimeToLive
);
```

The **SetTimeToLive** method sets the maximum time-to-live for the next ICMP datagram sent by the client.

Parameters

nTimeToLive

The time-to-live value for the next ICMP echo datagram.

Return Value

If the method succeeds, the return value is the previous time-to-live value. If the method fails, the return value is ICMP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The time-to-live (TTL) value is specified in the IP header of a datagram, and is used to control the number of routers that the datagram is passed through. Each router that handles the datagram decrements the TTL value by one. When it drops to zero, a datagram is returned to the sender, specifying that the TTL has been exceeded.

Calling this method changes the default TTL value for all subsequent ICMP datagrams sent by the library, with the default value being 255. Note that not all Windows Sockets implementations support setting the time-to-live value.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

See Also

CIcmpClient::ShowError Method

```
INT ShowError(
   LPCTSTR lpszAppTitle,
   UINT uType,
   DWORD dwErrorCode
);
```

The **ShowError** method displays a message box which describes the specified error.

Parameters

lpszAppTitle

A null-terminated string which specifies the title of the message box that is displayed. If this argument is NULL or omitted, then the default title of "Error" will be displayed.

uType

An unsigned integer which specifies the type of message box that will be displayed. This is the same value that is used by the **MessageBox** method in the Windows API. If a value of zero is specified, then a message box with a single OK button will be displayed. Refer to that method for a complete list of options.

dwErrorCode

Specifies the error code that will be used when displaying the message box. If this argument is zero, then the last error that occurred in the current thread will be displayed.

Return Value

If the method is successful, the return value will be the return value from the **MessageBox** function. If the method fails, it will return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetErrorString, GetLastError, SetLastError

CIcmpClient::TraceRoute Method

```
BOOL TraceRoute(
   LPCTSTR lpszHostName,
   UINT nMaxHops,
   DWORD dwTimeout
);
```

The **TraceRoute** method sends a series of ICMP echo datagrams to trace the route taken from the local system to the remote host.

Parameters

lpszHostName

A null-terminated string which specifies the fully qualified domain name of the remote host, or the IP address in dotted notation.

nMaxHops

An unsigned integer which specifies the maximum number of routers the datagram will be forwarded through (the number of hops) to the remote host. The minimum value is 1 and the maximum value is 255. It is recommended that most applications specify a value of at least 30.

dwTimeout

An unsigned integer which specifies the number of milliseconds the method will wait for a response to an echo datagram.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **TraceRoute** method sends a series of ICMP echo datagrams to the specified host, adjusting the time-to-live value to determine the intermediate hosts that route the packet. Use the **GetFirstHost** and **GetNextHost** methods to enumerate the hosts returned by the method.

It is important to note that the failure of an intermediate host to respond to an ICMP echo datagram may not indicate a problem with the remote system. Systems can be configured to specifically ignore ICMP echo datagrams and not respond to them; this is often a security measure to prevent certain kinds of Denial of Service attacks.

The ability to send ICMP datagrams may be restricted to users with administrative privileges, depending on the policies and configuration of the local system. If you are unable to send or receive any ICMP datagrams, it is recommended that you check the firewall settings and any third-party security software that could impact the normal operation of this component.

Example

```
BOOL bResult = pClient->TraceRoute(strAddress);
if (bResult)
{
    ICMPTRACE icmpTrace;

    bResult = pClient->GetFirstHost(icmpTrace);
    while (bResult)
    {
```

```
        // The icmpTrace structure contains information about the
        // intermediate host in the traceroute
        CString strHostName;
        pClient->ResolveAddress(icmpTrace.dwHostAddress, strHostName);

        bResult = pClient->GetNextHost(icmpTrace);
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

Internet Control Message Protocol Data Structures

- ICMPTIME
- ICMPTRACE
- INTERNET_ADDRESS
- SYSTEMTIME

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

ICMPTIME

This structure is used by the GetTripTime method to return the round-trip times of an ICMP datagram.

```
typedef struct _ICMPTIME {
    DWORD dwTripAverage;
    DWORD dwTripMaximum;
    DWORD dwTripMinimum;
    DWORD dwTripTime;
} ICMPTIME, *LPICMPTIME;
```

Members

dwTripAverage

The average round-trip time in milliseconds for all datagrams sent to the current host.

dwTripMaximum

The maximum round-trip time in milliseconds for all datagrams sent to current host.

dwTripMinimum

The minimum round-trip time in milliseconds for all datagrams sent to the current host.

dwTripTime

The current round-trip time in milliseconds for the last datagram sent to the current host.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

ICMPTRACE

This structure is used by the GetFirstHost and GetNextHost methods to return the route of an ICMP datagram.

```
typedef struct _ICMPTRACE
{
    UINT        nDistance;
    DWORD       dwHostAddress;
    DWORD       dwTripAverage;
    DWORD       dwTripMaximum;
    DWORD       dwTripMinimum;
} ICMPTRACE, *LPICMPTRACE;
```

Members

nDistance

The distance from the local host to the remote host for this route.

dwHostAddress

An unsigned integer which specifies the IP address of the remote host in network byte order.

dwTripAverage

The average round-trip time in milliseconds for all datagrams sent to the specified host.

dwTripMaximum

The maximum round-trip time in milliseconds for all datagrams sent to specified host.

dwTripMinimum

The minimum round-trip time in milliseconds for all datagrams sent to the specified host.

dwTripTime

The current round-trip time in milliseconds for the last datagram sent to the specified host.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

INTERNET_ADDRESS

This structure represents a numeric IPv4 or IPv6 address in network byte order.

```
typedef struct _INTERNET_ADDRESS
{
     INT    ipFamily;
     BYTE   ipNumber[16];
}  INTERNET_ADDRESS, *LPINTERNET_ADDRESS;
```

Members

ipFamily

An integer which identifies the type of IP address. It will be one of the following values:

Value	Description
INET_ADDRESS_UNKNOWN	The address has not been specified or the bytes in the ***ipNumber*** array does not represent a valid address. Functions which populate this structure will use this value to indicate that the address cannot be determined.
INET_ADDRESS_IPV4	Specifies that the address is in IPv4 format. The first four bytes of the ***ipNumber*** array are significant and contains the IP address. The remaining bytes are not significant and an application should not depend on them having any particular value, including zero.
INET_ADDRESS_IPV6	Specifies that the address is in IPv6 format. All bytes in the ***ipNumber*** array are significant. Note that it is possible for an IPv6 address to actually represent an IPv4 address. This is indicated by the first 10 bytes of the address being zero.

ipNumber

A byte array which contains the numeric form of the IP address. This array is large enough to store both IPv4 (32 bit) and IPv6 (128 bit) addresses. The values are stored in network byte order.

Remarks

The **INTERNET_ADDRESS** structure is used by some functions to represent an Internet address in a binary format that is compatible with both IPv4 and IPv6 addresses. Applications that use this structure should consider it to be opaque, and should not modify the contents of the structure directly.

For compatibility with legacy applications that expect an IP address to be 32 bits and stored in an unsigned integer, you can copy the first four bytes of the ***ipNumber*** array using the **CopyMemory** function or equivalent. Note that if this is done, your application should always check the ***ipFamily*** member first to make sure that it is actually an IPv4 address.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SYSTEMTIME

The **SYSTEMTIME** structure represents a date and time using individual members for the month, day, year, weekday, hour, minute, second, and millisecond.

```
typedef struct _SYSTEMTIME
{
    WORD wYear;
    WORD wMonth;
    WORD wDayOfWeek;
    WORD wDay;
    WORD wHour;
    WORD wMinute;
    WORD wSecond;
    WORD wMilliseconds;
} SYSTEMTIME, *LPSYSTEMTIME;
```

Members

wYear

Specifies the current year. The year value must be greater than 1601.

wMonth

Specifies the current month. January is 1, February is 2 and so on.

wDayOfWeek

Specifies the current day of the week. Sunday is 0, Monday is 1 and so on.

wDay

Specifies the current day of the month

wHour

Specifies the current hour.

wMinute

Specifies the current minute

wSecond

Specifies the current second.

wMilliseconds

Specifies the current millisecond.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: windows.h.

Internet Message Access Protocol Class Library

Manage email messages and mailboxes on a mail server.

Reference

- Class Methods
- Data Structures
- Error Codes

Library Information

Class Name	CImapClient
File Name	CSMAPV12.DLL
Version	12.0.3024.1286
LibID	8A55FC0D-5E12-4932-9E86-1F88C1DF5024
Import Library	CSMAPV12.LIB
Dependencies	None
Standards	RFC 3501

Overview

The Internet Message Access Protocol (IMAP) is an application protocol which is used to access a user's email messages which are stored on a mail server. However, unlike the Post Office Protocol (POP) where messages are downloaded and processed on the local system, the messages on an IMAP server are retained on the server and processed remotely. This is ideal for users who need access to a centralized store of messages or have limited bandwidth. For example, traveling salesmen who have notebook computers or mobile users on a wireless network would be ideal candidates for using IMAP.

The SocketTools IMAP library implements the current standard for this protocol, and provides methods to retrieve messages, or just certain parts of a message, create and manage mailboxes, search for specific messages based on certain criteria and so on. The API is designed as a superset of the Post Office Protocol API, so developers who are used to working with the POP3 library will find the IMAP library very easy to integrate into an existing application.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). You should install all updates for your development tools and have the current Windows SDK installed. The minimum supported version of Visual Studio is Visual Studio 2010 with Service Pack 1 (SP1) installed. The SocketTools header files are designed to be compatible with all modern C/C++ compilers and we also provide function definitions for several additional languages such as Object Pascal and Visual Basic.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are deploying applications to Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. If you are deploying applications to Windows 8, you must have the 8.1 update installed. If you are targeting the Windows on ARM platform, the minimum required version is Windows 10 build 1709.

SocketTools includes support for both 64-bit and 32-bit Windows platforms. All current versions of Windows are 64-bit, and we include 32-bit x86 libraries to maintain compatibility with legacy development tools. SocketTools also provides native ARM64 libraries for systems running Windows on ARM. Note that 32-bit applications on ARM use x86 emulation, and Microsoft no longer supports native 32-bit ARM (ARM32) applications. Embarcadero's C++Builder and Delphi compilers (as of version 12.3) do not support building native ARM64 applications for Windows. For developing applications targeting the Windows on ARM platform, we recommend using Visual Studio 2019 or later.

The import libraries included with SocketTools are provided in several different formats. The most commonly used format is COFF, which is available for x64, x86 and native ARM64 platforms. For compatibility with older Borland (Embarcadero) compilers, we also provide OMF libraries for x86 platforms and ELF libraries for x64 platforms. If you are using Visual Studio, you will want to use the standard COFF import libraries. Note that some languages may not require import libraries and will link to the exported functions in the DLL based on the function declaration itself.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Internet Message Access Protocol Class Methods

Class	Description
CImapClient	Constructor which initializes the current instance of the class
~CImapClient	Destructor which releases resources allocated by the class
Method	Description
AttachHandle	Attach the specified client handle to this instance of the class
AttachThread	Attach the specified client handle to another thread
Cancel	Cancel the current blocking operation
CheckMailbox	Check the current mailbox for new messages
CloseMessage	Close the current message
Command	Send a command to the server
Connect	Connect to the specified server
CopyMessage	Copy a message from the current mailbox to another mailbox
CreateMailbox	Create a new mailbox on the server
CreateMessage	Create a new message in the specified mailbox
CreateSecurityCredentials	Allocate a structure to establish client security credentials
DecodeMailboxName	Decode a UTF-7 encoded mailbox name using the specified code page
DeleteMailbox	Delete the specified mailbox from the server
DeleteMessage	Delete the specified message from the mailbox
DeleteSecurityCredentials	Delete the specified client security credentials
DetachHandle	Detach the handle for the current instance of this class
DisableEvents	Disable the event notification mechanism
DisableTrace	Disable logging of network function calls
Disconnect	Disconnect from the current server
EnableEvents	Enable the client event notification mechanism
EnableTrace	Enable logging of network function calls to a file
EncodeMailboxName	Encode a mailbox name using modified UTF-7 encoding
EnumMessages	Enumerate the messages in the current mailbox
ExamineMailbox	Select the specified mailbox in read-only mode
ExpungeMailbox	Remove messages that have been marked for deletion from the current mailbox
FreezeEvents	Suspend and resume event handling by the client
GetCapability	Return a string which identifies the capabilities of the server
GetCurrentMailbox	Return the name of the currently selected mailbox

GetDeletedMessages	Return the messages that have been marked for deletion
GetErrorString	Return a description for the specified error code
GetFirstMailbox	Return the first mailbox according to specified criteria
GetHandle	Return the client handle used by this instance of the class
GetHeaderValue	Return the value of the specified header field
GetIdleThreadId	Return the ID of the thread created to monitor the client session
GetLastError	Return the last error code
GetMailboxDelimiter	Get the path delimiter for the specified mailbox hierarchy
GetMailboxSize	Return the size of the specified mailbox
GetMailboxStatus	Return the status of the specified mailbox
GetMailboxUID	Return the unique identifier for the specified mailbox
GetMessage	Retrieve the specified message from the server
GetMessageCount	Return the number of messages available in the mailbox
GetMessageFlags	Return the status flags for the specified message
GetMessageHeaders	Retrieve the specified message header from the server
GetMessageId	Return the message ID string for the specified message
GetMessageParts	Return the number of MIME message parts in the specified message
GetMessageSender	Return the address of the message sender
GetMessageSize	Return the size of the specified message
GetMessageUID	Return the unique identifier for the specified message
GetNewMessages	Return a list of the new messages in the current mailbox
GetNextMailbox	Return the next mailbox name on the server
GetResultCode	Return the result code from the previous command
GetResultString	Return the result string from the previous command
GetSecurityInformation	Return security information about the current client connection
GetStatus	Return the current status of the client
GetTimeout	Return the number of seconds until an operation times out
GetTransferStatus	Return data transfer statistics
GetUnseenMessages	Return a list of messages from the current mailbox that have not been read
Idle	Enables mailbox status monitoring for the client session
ImapEventProc	Callback method that processes events generated by the client
ImapIdleProc	Callback function that receives update notifications from the server
IsBlocking	Determine if the client is blocked, waiting for information
IsConnected	Determine if the client is connected to the server
IsInitialized	Determine if the class has been successfully initialized

IsReadable	Determine if data can be read from the server
IsWritable	Determine if data can be written to the server
Login	Login to the server
OpenMessage	Open the specified message for reading on the server
Read	Read data returned by the server
RegisterEvent	Register an event handler for the specified event
RenameMailbox	Rename the specified mailbox
ReselectMailbox	Reselect the current mailbox and return updated status information
SearchMailbox	Search the mailbox according to specified criteria
SelectMailbox	Select the specified mailbox in read-write mode
SetLastError	Set the last error code for the current thread
SetMessageFlags	Set one or more status flags for the specified message
SetTimeout	Set the number of seconds until an operation times out
ShowError	Display a message box with a description of the specified error
StoreMessage	Store the contents of a message to the specified file
SubscribeMailbox	Subscribe to the specified mailbox
UndeleteMessage	Undelete the specified message from the current mailbox
UnselectMailbox	Unselect the current mailbox and expunge any deleted messages
UnsubscribeMailbox	Unsubscribe from the specified mailbox
Write	Write data to the server

CImapClient::~CImapClient

```
~CImapClient();
```

The **CImapClient** destructor releases resources allocated by the current instance of the **CImapClient** object. It also uninitializes the library if there are no other concurrent uses of the class.

Remarks

When a **CImapClient** object goes out of scope, the destructor is automatically called to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all handles that were created for the client session are destroyed.

The destructor is not called explicitly by the application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CImapClient

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CImapClient::AttachHandle Method

```
VOID AttachHandle(
   HCLIENT hClient
);
```

The **AttachHandle** method attaches the specified client handle to the current instance of the class.

Parameters

hClient

The handle to the client session that will be attached to the current instance of the class object.

Return Value

None.

Remarks

This method is used to attach a client handle created outside of the class using the SocketTools API. Once the client handle is attached to the class, the other class member functions may be used with that client session.

If a client handle has already been created for the class, that handle will be released when the new handle is attached to the class object. If you want to prevent the previous client session from being terminated, you must call the **DetachHandle** method. Failure to release the detached handle may result in a resource leak in your application.

Note that the ***hClient*** parameter is presumed to be a valid client handle and no checks are performed to ensure that the handle is valid. Specifying an invalid client handle will cause subsequent method calls to fail.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

See Also

AttachThread, DetachHandle, GetHandle

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CImapClient::AttachThread Method

```
DWORD AttachThread(
   DWORD dwThreadId
);
```

The **AttachThread** method attaches the specified client handle to another thread.

Parameters

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the method succeeds, the return value is the thread ID of the previous owner. If the method fails, the return value is IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

When a client handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in a client application to create the client handle, and then pass that handle to another worker thread. The **AttachThread** method can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the method, the original owner of the handle can be restored before the worker thread terminates.

This method should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **AttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **Cancel** method and then release the handle after the blocking method exits and control is returned to the current thread.

Note that the ***dwThreadId*** parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the client handle used by the class until the destructor is called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

See Also

AttachHandle, Cancel, Connect, DetachHandle, Disconnect, GetHandle

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CImapClient::Cancel Method

```
INT Cancel();
```

The **Cancel** method cancels any outstanding blocking operation in the client, causing the blocking method to fail. The application may then retry the operation or terminate the client session.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

When the **Cancel** method is called, the blocking method will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

CImapClient::CheckMailbox Method

```
INT CheckMailbox(
   UINT *lpnMessages,
   UINT *lpnUnseen
);
```

The **CheckMailbox** method requests that the server create a checkpoint of the currently selected mailbox, and returns the current number of messages and unseen messages.

Parameters

lpnMessages

A pointer to an unsigned integer value which will contain the number of messages in the currently selected mailbox when the method returns.

lpnUnseen

A pointer to an unsigned integer value which will contain the number of unseen messages in the currently selected mailbox.

Return Value

If the method succeeds, it returns zero. If an error occurs, the method returns IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

When the client requests a checkpoint, the server may perform implementation-dependent housekeeping for that mailbox, such updating the mailbox on disk with the current state of the mailbox in memory. On some systems this command has no effect other than to update the client with the current number of messages in the mailbox.

This method actually sends two IMAP commands. The first is the CHECK command, followed by the NOOP command to poll for any new messages that have arrived. In addition to polling the server for new messages, this command can also be used to ensure the idle timer on the server does not expire and force a disconnect from the client.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

See Also

CImapClient::CImapClient Method

```
CImapClient();
```

The **CImapClient** constructor initializes the class library and validates the license key at runtime.

Remarks

If the constructor fails to validate the runtime license, subsequent methods in this class will fail. If the product is installed with an evaluation license, then the application will only function on the development system and cannot be redistributed.

The constructor calls the **ImapInitialize** function to initialize the library, which dynamically loads other system libraries and allocates thread local storage. If you are using this class within another DLL, it is important that you do not create or destroy an instance of the class from within the **DllMain** function because it can result in deadlocks or access violation errors. You should not declare static or global instances of this class within another DLL if it is linked with the C runtime library (CRT) because it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

~CImapClient, IsInitialized

CImapClient::CloseMessage Method

```
INT CloseMessage();
```

The **CloseMessage** method closes the current message.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **CloseMessage** method closes the current message. If there is any remaining data left to be read from the message, it will be read and discarded.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

CImapClient::Command Method

```
INT Command(
   LPCTSTR lpszCommand,
   LPCTSTR lpszParameter
);
```

The **Command** method sends a command to the server. This method is typically used for site-specific commands not directly supported by the API.

Parameters

lpszCommand

The command which will be executed by the server.

lpszParameter

An optional command parameter. If the command requires more than one parameter, then they should be combined into a single string, with a space separating each parameter. If the command does not accept any parameters, this value may be NULL.

Return Value

If the method succeeds, it returns an IMAP result code. If the command was successful, it returns IMAP_RESULT_OK. A return value of IMAP_RESULT_CONTINUE indicates the command was accepted and the caller should proceed with the next command. If an error occurs, the method returns IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

A list of valid commands can be found in the technical specification for the protocol. The current version of the protocol which is supported by this library is version 4rev1 as defined in RFC 3501.

Use the **GetResultCode** method to determine the result of the command that was sent to the server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

CImapClient::Connect Method

```
BOOL Connect(
   LPCTSTR lpszHostName,
   UINT nRemotePort,
   UINT nTimeout,
   DWORD dwOptions
);
```

The **Connect** method is used to establish a connection with the server.

Parameters

lpszHostName

A null-terminated string which specifies the host name or IP address of the IMAP server.

nRemotePort

The port number the client should use to establish the connection. A value of zero specifies that default port 143 should be used, which is the standard port number assigned to the IMAP service. If the secure port number is specified, an implicit TLS connection will be established by default.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer value which specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
IMAP_OPTION_NONE	No connection options specified. A standard connection to the server will be established using the specified host name and port number.
IMAP_OPTION_IDENTIFY	This option specifies the client should identify itself to the server. If enabled, the client will send the ID command to the server as defined in RFC 2971. This option has no effect if the server does not support the ID command.
IMAP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
IMAP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
IMAP_OPTION_SECURE	This option specifies that a secure connection should be established with the server and requires that the

	server support the TLS protocol. This option is the same as specifying IMAP_OPTION_SECURE_EXPLICIT, which initiates the secure session using the STARTTLS command.
IMAP_OPTION_SECURE_EXPLICIT	This option specifies the client should attempt to establish a secure connection with the server. The server must support secure connections using the TLS protocol and the STARTTLS command.
IMAP_OPTION_SECURE_IMPLICIT	This option specifies the client should attempt to establish a secure connection with the server. The server must support secure connections using the TLS protocol, and the secure session must be negotiated immediately after the connection has been established.
IMAP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
IMAP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
IMAP_OPTION_FREETHREAD	This option specifies that this instance of the class may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the class instance is synchronized across multiple threads.

hEventWnd

The handle to the asynchronous notification window. This window receives messages which notify the client of various asynchronous client events that occur. Specifying this parameter and a message identifier causes the connection to be non-blocking. If this parameter is NULL, then a blocking connection is established.

uEventMsg

The message identifier that is used when an asynchronous client event occurs. This value should be greater than WM_USER as defined in the Windows header files. If the ***hEventWnd*** parameter is NULL, this parameter should be specified as WM_NULL.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method will block the current thread until a connection has been established or the timeout period has elapsed. To prevent it from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling the **Connect** method in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each connection.

The *dwOptions* argument can be used to specify the threading model that is used by the class when a connection is established. By default, the client session is initially attached to the thread that created it. From that point on, until the connection is terminated, only the owner may invoke methods in that instance of the class. The ownership of the class instance may be transferred from one thread to another using the **AttachThread** method.

Specifying the IMAP_OPTION_FREETHREAD option enables any thread to call methods in any instance of the class, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the class and may result in unexpected behavior unless access to the class instance is synchronized. If one thread calls a method in the class, it must ensure that no other thread will call another method at the same time using the same instance.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

CImapClient::CopyMessage Method

```
INT CopyMessage(
   UINT nMessageId,
   LPCTSTR lpszMailbox
);
```

The **CopyMessage** method copies a message from the current mailbox to the specified mailbox. The message is appended to the mailbox, and the message flags and internal date are preserved.

Parameters

nMessageId

The message identifier which specifies which message is to be copied to the mailbox. This value must be greater than zero and specify a valid message number.

lpszMailbox

A null-terminated string which specifies the name of the mailbox that the message will be copied to. The mailbox must already exist, and the client must have the appropriate access rights to modify the mailbox.

Return Value

If the method succeeds, it returns a value of zero. If an error occurs, the method returns IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

If the mailbox does not exist, the method will fail. To create a new mailbox, use the **CreateMailbox** method. A message can be copied within the same mailbox, in which case the server may flag it as a new message.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CreateMailbox, GetResultCode, GetResultString

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CImapClient::CreateMailbox Method

```
INT CreateMailbox(
   LPCTSTR lpszMailbox
);
```

The **CreateMailbox** method creates a new mailbox on the server.

Parameters

lpszMailbox

A null-terminated string which specifies the new mailbox to be created.

Return Value

If the method succeeds, it returns a value of zero. If an error occurs, the method returns IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

If the mailbox name is suffixed with the server's hierarchy delimiter, this indicates to the server that the client intends to create mailbox names under the specified name in the hierarchy. If superior hierarchical names are specified in the mailbox name, then the server may automatically create them as needed. For example, if the mailbox name "Mail/Office/Projects" is specified and "Mail/Office" does not exist, it may be automatically created by the server.

The special mailbox name INBOX is reserved, and cannot be created. It is recommended that mailbox names only consist of printable ASCII characters, and the special characters "*" and "%" should be avoided. If you need to create a mailbox which contains Unicode characters or symbols, your application should be compiled to use the Unicode character set to ensure that the mailbox name is encoded correctly. If you do not use Unicode, this method will only accept mailbox names using either modified UTF-7 encoding or UTF-8 encoding.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

DeleteMailbox, GetFirstMailbox, GetNextMailbox, RenameMailbox

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CImapClient::CreateMessage Method

```
INT CreateMessage(
   LPCTSTR lpszMailbox,
   LPBYTE lpMessage,
   DWORD dwMessageSize,
   DWORD dwFlags
);

INT CreateMessage(
   LPCTSTR lpszMailbox,
   LPCTSTR lpszMessage,
   DWORD dwFlags
);
```

The **CreateMessage** method creates a message, appending it to the contents of the specified mailbox.

Parameters

lpszMailbox

A null-terminated string which specifies the name of the mailbox that the message will be created in. The mailbox must already exist, and the client must have the appropriate access rights to modify the mailbox.

lpMessage

The buffer which contains the data for the message to be created. An alternate form of the method accepts a pointer to a string.

dwMessageSize

An unsigned integer value which specifies the size of the message data in bytes.

dwFlags

An unsigned integer that specifies one or more message flags. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
IMAP_FLAG_NONE	No value.
IMAP_FLAG_ANSWERED	The message has been answered.
IMAP_FLAG_DRAFT	The message is not completed and is marked as a draft copy.
IMAP_FLAG_URGENT	The message is flagged for urgent or special attention.
IMAP_FLAG_SEEN	The message has been read.

Return Value

If the method succeeds, it returns zero. If an error occurs, the method returns IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

If the mailbox does not exist, the method will fail. To create a new mailbox, use the **CreateMailbox** method. If the message is created in the mailbox that is currently selected, the server may flag it as recent.

This method is typically used by applications to store messages which have already been sent to a user. After a message has been delivered using the SMTP protocol, that same message may be created in a mailbox on the IMAP server so that the user has access to those messages.

If the Unicode version of this method is called and the ***dwMessageSize*** parameter is zero, the ***lpMessage*** parameter must point to a wide string terminated with a null character. The string will be automatically converted to UTF-8 when the message is created. In all other cases, the ***lpMessage*** parameter is treated as a pointer to a byte array which contains the message contents and the ***dwMessageSize*** parameter specifies the number of bytes in the array.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

CImapClient::CreateSecurityCredentials Method

```
BOOL CreateSecurityCredentials(
   DWORD dwProtocol,
   DWORD dwOptions,
   LPCTSTR lpszUserName,
   LPCTSTR lpszPassword,
   LPCTSTR lpszCertStore,
   LPCTSTR lpszCertName
);

BOOL CreateSecurityCredentials(
   LPCTSTR lpszCertStore,
   LPCTSTR lpszCertName
);

BOOL CreateSecurityCredentials(
   LPCTSTR lpszCertName
);
```

The **CreateSecurityCredentials** method creates the security credentials for the client session.

Parameters

dwProtocol

A bitmask of supported security protocols. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_TLS	Either the TLS 1.2 or 1.3 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers which reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows

	Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwOptions

A value which specifies one or more options. This member is constructed by using a bitwise operator with any of the following values:

Value	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

lpszUserName

A null-terminated string which specifies the certificate owner's username. A value of NULL specifies that no username is required. Currently this parameter is not used and any value specified will be ignored.

lpszPassword

A null-terminated string which specifies the certificate owner's password. A value of NULL specifies that no password is required. This parameter is only used if a PKCS #12 (PFX) certificate file is specified and that certificate has been secured with a password. This value will be ignored the current user or local machine certificate store is specified.

lpszCertStore

A null-terminated string which specifies the name of the certificate store to open. A certificate store

is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A null-terminated string which specifies the name of the certificate to use. The method will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the method will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the method will return an error indicating that the certificate could not be found.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

A client application only needs to call this method if the server requires that the client provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The ***dwOptions*** parameter should be set to CREDENTIAL_STORE_FILENAME and the ***lpszCertStore*** parameter should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS #12.These certificate files typically have an extension of .pfx or .p12. If a password was specified when the certificate was

created, it must be provided in the *lpszPassword* parameter or the library will be unable to access the certificate.

Note that the *lpszUserName* and *lpszPassword* parameters are optional values which are used to access the certificate store or client certificate. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session. In most cases, these parameters can be NULL or omitted.

Example

```
pClient->CreateSecurityCredentials(
            SECURITY_PROTOCOL_DEFAULT,
            0,
            NULL,
            NULL,
            lpszCertStore,
            lpszCertName);

bConnected = pClient->Connect(lpszHostName,
                              IMAP_PORT_SECURE,
                              IMAP_TIMEOUT,
                              IMAP_OPTION_SECURE);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

CImapClient::DecodeMailboxName Method

```
INT DecodeMailboxName(
   LPCSTR lpszMailboxName,
   LPTSTR lpszDecodedName,
   INT nMaxLength,
   INT nCodePage
);

INT DecodeMailboxName(
   LPCSTR lpszMailboxName,
   CString& strDecodedName,
   INT nCodePage
);
```

The **DecodeMailboxName** method decodes a UTF-7 encoded mailbox name using the specified code page.

Parameters

lpszMailboxName

A null-terminated string which contains the UTF-7 encoded name of the mailbox. The encoded string must use the modified UTF-7 format defined in the IMAP4 protocol standard. This parameter cannot be a NULL pointer or an empty string.

lpszDecodedName

A null-terminated string buffer which will contain the decoded mailbox name. This parameter cannot be NULL and must be large enough to contain the entire name. An alternate form of the method accepts a **CString** object which will contain the decoded mailbox name when the method returns.

nMaxLength

An integer value which specifies the maximum number of characters which can be copied into the *lpszDecodedName* string buffer. This value must be greater than zero and the buffer must be large enough to store the entire name.

nCodePage

An optional integer value which specifies the code page used when decoding the mailbox name. If the application does not use Unicode, this parameter can be any valid code page. The default value is CP_ACP which specifies the current active code page for the locale. Applications which are built using Unicode should always use the default value.

Return Value

If the method succeeds, it returns the number of characters in the decoded mailbox name. If an error occurs, the method returns zero. To get extended error information, call **GetLastError**.

Remarks

Mailbox names which contain non-ASCII characters must be converted to a modified version of UTF-7 encoding as defined by the IMAP4 protocol. This encoding allows applications to reference mailbox names which contain Unicode characters and provides support for languages other than English. This method is used to convert a UTF-7 encoded mailbox name using the current locale, primarily for display purposes.

For example, if the *lpszMailboxName* parameter specifies the string **"&A5QDvwO6A7kDvAOu-"**, this

method will convert it to the Greek word **"Δοκιμή"** and return that value in the *lpszDecodedName* buffer. It is recommended you use the Unicode version of this method whenever possible to ensure the mailbox name is decoded correctly.

If the application is not built using Unicode, the decoded mailbox name will be converted using the code page specified by the *nCodePage* parameter. If the code page does not support the characters used in the mailbox name, this can result in an incorrect conversion.

This method should not be used to convert strings between Unicode and UTF-7. The encoding format is specifically intended for use with the IMAP4 protocol and should never be used for general purpose encoding or decoding. If you need to convert a UTF-7 encoded string to Unicode, use the Win32 API function **MultiByteToWideChar**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CImapClient::DeleteMailbox Method

```
INT DeleteMailbox(
   LPCTSTR lpszMailbox
);
```

The **DeleteMailbox** method deletes a mailbox on the server.

Parameters

lpszMailbox

A null-terminated string which specifies the mailbox to be deleted.

Return Value

If the method succeeds, it returns value of zero. If an error occurs, the method returns IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

A mailbox cannot be deleted if it contains inferior hierarchical names and has the IMAP_FLAG_NOSELECT attribute. On most systems this is the case when the mailbox name references a directory on the server, and that directory contains other subdirectories or mailboxes. To remove the mailbox, you must first delete any child mailboxes that exist.

If the mailbox that is deleted is the currently selected mailbox, it will be automatically unselected and any messages marked for deletion will be expunged before the mailbox is removed. If the delete operation fails, the client will remain in an unselected state until either the **ExamineMailbox** or **SelectMailbox** method is called.

The special mailbox name INBOX is reserved, and cannot be deleted.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

CImapClient::DeleteMessage Method

```
INT DeleteMessage(
   UINT nMessageId
);
```

The **DeleteMessage** method marks the specified message for deletion from the current mailbox.

Parameters

nMessage

Number of message to delete from the server. This value must be greater than zero. The first message in the mailbox is message number one.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

This method only marks the message for deletion. The message is not actually deleted until the mailbox is expunged or another mailbox is selected. This method will return an error if the current mailbox is in read-only mode, such as if it was selected using the **ExamineMailbox** method.

It is important to note that unlike the POP3 protocol, a message that is marked for deletion is still accessible on the IMAP server until the mailbox is expunged. This means, for example, that a deleted message can still be retrieved using the **GetMessage** method.

To determine if a message has been marked for deletion, use the **GetMessageFlags** method and check if the IMAP_FLAG_DELETED bit flag has been set. To list all of the deleted messages in the current mailbox, use the **GetDeletedMessages** method.

To remove the deletion flag from the message, use the **UndeleteMessage** method. To prevent all messages in the current mailbox from being expunged, use the **ReselectMailbox** method to reset the current mailbox state.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

CImapClient::DeleteSecurityCredentials Method

```
VOID DeleteSecurityCredentials();
```

The **DeleteSecurityCredentials** method releases the security credentials for the current session.

Parameters

None.

Return Value

None.

Remarks

This method can be used to release the memory allocated to the client or server credentials after a secure connection has been terminated. The security credentials are released when the class destructor is called, so it is normally not required that the application explicitly call this method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

CreateSecurityCredentials

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CImapClient::DetachHandle Method

```
HCLIENT DetachHandle();
```

The **DetachHandle** method detaches the client handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the client handle associated with the current instance of the class object. If there is no active client session, the value INVALID_CLIENT will be returned.

Remarks

This method is used to detach a client handle created by the class for use with the SocketTools API. Once the client handle is detached from the class, no other class member functions may be called. Note that the handle must be explicitly released at some later point by the process or a resource leak will occur.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

CImapClient::DisableEvents Method

```
INT DisableEvents();
```

The **DisableEvents** method disables the event notification mechanism, preventing subsequent event notification messages from being posted to the application's message queue.

This method has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **DisableEvents** method is used to disable event message posting for the specified client session. Although this will immediately prevent any new events from being generated, it is possible that messages could be waiting in the message queue. Therefore, an application must be prepared to handle client event messages after this method has been called.

This method is automatically called if the client has event notification enabled, and the **Disconnect** method is called. The same issues regarding outstanding event messages also applies in this situation, requiring that the application handle event messages that may reference a client handle that is no longer valid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

CImapClient::DisableTrace Method

```
BOOL DisableTrace();
```

The **DisableTrace** method disables the logging of network function calls.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, a value of zero is returned.

Remarks

This method will disable output to the log file for the current thread or process, depending on the flags used when logging was enabled. If this method is not called, the resources that were allocated for the logging session will be released when the process ends.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

CImapClient::EnableEvents Method

```
INT EnableEvents(
   HWND hEventWnd,
   UINT uEventMsg
);
```

The **EnableEvents** method enables event notifications using Windows messages.

This method has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Applications should use the **RegisterEvent** method to register an event handler which is invoked when an event occurs.

Parameters

hEventWnd

Handle to the window which will receive the client notification messages. This parameter must specify a valid window handle. If a NULL handle is specified, event notification will be disabled.

uEventMsg

The message that is received when a client event occurs. This value must be greater than 1024.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **EnableEvents** method is used to request that notification messages be posted to the specified window whenever a client event occurs. This allows an application to monitor the status of different client operations, such as a file transfer.

The *wParam* argument will contain the client handle, the low word of the *lParam* argument will contain the event ID, and the high word will contain any error code. If no error has occurred, the high word will always have a value of zero. The following events may be generated:

Value	Description
IMAP_EVENT_CONNECT	The connection to the server has completed. The high word of the *lParam* parameter should be checked, since this notification message will be posted if an error has occurred.
IMAP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
IMAP_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
IMAP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This

	event is only generated if the client is in asynchronous mode.
IMAP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
IMAP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
IMAP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.
IMAP_EVENT_PROGRESS	The client is in the process of sending or receiving a file on the data channel. This event is called periodically during a transfer so that the client can update any user interface components such as a status control or progress bar.

It is not required that the client be placed in asynchronous mode in order to receive command and progress event notifications. To disable event notification, call the **DisableEvents** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

CImapClient::EnableTrace Method

```
BOOL EnableTrace(
   LPCTSTR lpszTraceFile,
   DWORD dwTraceFlags
);
```

The **EnableTrace** method enables the logging of network function calls to a file.

Parameters

lpszTraceFile

A null-terminated string which specifies the name of the logfile which will be appended to or created. It is recommended that this file always specify an absolute path to avoid any ambiguity. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
TRACE_INFO	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
TRACE_ERROR	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
TRACE_HEXDUMP	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
TRACE_TRUNCATE	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for

	multithreaded applications that are using worker threads.

Return Value

If the method succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the log file cannot be created.

Remarks

Logging is enabled and disabled at the thread or process level, depending on the flags passed to this method, and is not associated with a specific class instance. When logging is enabled, the information is appended to the specified file. If the file does not exist, it will be created. To limit the size of the file, enable and disable logging only around those sections of code that you wish to debug. If you do not provide a full path to the file, it will be relative to the current working directory for the process. This can produce unexpected results in multithreaded applications because the current directory is global to the entire process and can be changed by any thread at any time.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

The TRACE_HEXDUMP option can generate very large files because it includes all of the data exchanged between your application and the remote host. The TRACE_TRUNCATE option is only evaluated when logging is first enabled for a thread or process. If logging is already active, specifying this option will have no effect.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "**0x**". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxxx:xxxx::xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, a connection is being made to a system with the IPv4 address 192.0.0.1 on port 1234.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

CImapClient::EncodeMailboxName Method

```
INT EncodeMailboxName(
   LPCTSTR lpszMailboxName,
   LPTSTR lpszEncodedName,
   INT nMaxLength,
   INT nCodePage
);

INT EncodeMailboxName(
   LPCTSTR lpszMailboxName,
   CString& strEncodedName,
   INT nCodePage
);
```

The **EncodeMailboxName** method encodes a mailbox name using modified UTF-7 encoding.

Parameters

lpszMailboxName

A null-terminated string which contains the name of the mailbox. If the application does not use Unicode, this string is automatically converted to Unicode using the code page specified by the *nCodePage* parameter. This parameter cannot be a NULL pointer or an empty string.

lpszEncodedName

A null-terminated string buffer which will contain the UTF-7 encoded mailbox name. This parameter cannot be NULL and must be large enough to contain the entire name. The string will be null-terminated and will only contain printable ASCII characters. An alternate form of the method accepts a **CString** object which will contain the decoded mailbox name when the method returns.

nMaxLength

An integer value which specifies the maximum number of characters which can be copied into the *lpszEncodedName* string buffer. This value must be greater than zero and the buffer must be large enough to store the entire name.

nCodePage

An optional integer value which specifies the code page used when decoding the mailbox name. If the application does not use Unicode, this parameter can be any valid code page. The default value is CP_ACP which specifies the current active code page for the locale. Applications which are built using Unicode should always use the default value.

Return Value

If the method succeeds, it returns the number of characters in the encoded mailbox name. If an error occurs, the method returns zero. To get extended error information, call **GetLastError**.

Remarks

Mailbox names which contain non-ASCII characters must be converted to a modified version of UTF-7 encoding as defined by the IMAP4 protocol. This encoding allows applications to reference mailbox names which contain Unicode characters and provides support for languages other than English. This method is used to convert a mailbox name which contains non-ASCII characters to the UTF-7 encoded required by IMAP servers.

For example, if the *lpszMailboxName* parameter specifies the string **"Δοκιμή"**, this method will encode it as **"&A5QDvwO6A7kDvAOu-"** and return that value in the *lpszEncodedName* buffer. It is

recommended you compile the application using the Unicode character set whenever possible to ensure the mailbox name is encoded correctly.

If the application is not compiled using Unicode, the mailbox name will be automatically converted to Unicode using the code page specified by the ***nCodePage*** parameter. If the code page does not support the characters used in the mailbox name, this can result in an incorrect conversion. Using the previous example, the mailbox name will always encode correctly if the Unicode version of the method is used, but the ANSI version of the method will only encode it correctly if the code page is specified as 1253 (Greek).

This method should not be used to convert strings between Unicode and UTF-7. The encoding format is specifically intended for use with the IMAP4 protocol and should never be used for general purpose encoding or decoding. If you need to convert a Unicode string to UTF-7, use the Win32 API function **WideCharToMultiByte**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CImapClient::EnumMessages Method

```
INT EnumMessages(
   UINT nFirstMessageId,
   UINT nLastMessageId,
   DWORD dwMessageFlags,
   LPIMAPMESSAGE lpMessageList,
   INT nMaxMessages
);

INT EnumMessages(
   LPIMAPMESSAGE lpMessageList,
   INT nMaxMessages
);
```

The **EnumMessages** method enumerates the messages in the current mailbox, populating an array of IMAPMESSAGE structures which contain information about each message.

Parameters

nFirstMessageId

An unsigned integer value which specifies the first message to enumerate. This value must be greater than zero and specify a valid message identifier. The first message in the mailbox has a value of one.

nLastMessageId

An unsigned integer value which specifies the last message to enumerate. This value must be greater than or equal to the value of the ***nFirstMessageId*** parameter. A special value of 0xFFFFFFFF can be used to specify the last message in the mailbox.

dwMessageFlags

This parameter is used to determine which messages are enumerated. If the value is zero, then all applicable messages will be enumerated. If the value is non-zero, only those messages which have at least one of the specified flags will be returned. More than one flag can be specified by using a bitwise operator.

Value	Description
IMAP_FLAG_ANSWERED	Return only those messages which have been answered.
IMAP_FLAG_DELETED	Return only those messages which have been marked for deletion.
IMAP_FLAG_DRAFT	Return only those messages which have been marked as draft copies.
IMAP_FLAG_URGENT	Return only those messages which have been flagged for urgent or special attention.
IMAP_FLAG_RECENT	Return only those messages which have been recently added to the mailbox.
IMAP_FLAG_SEEN	Return only those messages which have been read.

dwReserved

A reserved parameter. This value should always be set to zero.

lpMessageList

A pointer to an array of IMAPMESSAGE structures which will contain information about each of the messages returned by the server. This parameter cannot be NULL.

nMaxMessages

An integer value which specifies the maximum size of the IMAPMESSAGE array that was passed to the function. This value must be at least one.

Return Value

If the method succeeds, the return value is the number of messages that were enumerated. If no messages match the specified criteria, the method will return a value of zero. If an error is encountered, the method returns IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

If the message UID is being stored locally by the client to identify the message over multiple sessions, it must also store the mailbox UID. Only the combination of the mailbox name, mailbox UID and message UID can be used to uniquely identify a given message on the server. Although IMAP server implementations are encouraged to maintain persistent message UIDs, they are not required to do so and those values may change if the mailbox UID changes.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

See Also

GetMessage, GetMessageCount, GetMessageFlags, GetMessageHeaders, GetMessageSize, GetMessageUID, IMAPMESSAGE

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CImapClient::EnumMessageUids Method

```
INT EnumMessageUids(
   UINT nFirstMessageId,
   UINT nLastMessageId,
   DWORD dwMessageFlags,
   UINT *lpSequenceIdList,
   UINT *lpMessageUidList
   INT nMaxMessages
);

INT EnumMessageUids(
   UINT *lpSequenceIdList,
   DWORD *lpMessageUidList
   INT nMaxMessages
);
```

The **EnumMessageUids** method populates an array of message sequence IDs and their corresponding message UIDs.

Parameters

nFirstMessageId

An unsigned integer value which specifies the first message to enumerate. This value must be greater than zero and specify a valid message identifier. The first message in the mailbox has a value of one.

nLastMessageId

An unsigned integer value which specifies the last message to enumerate. This value must be greater than or equal to the value of the ***nFirstMessageId*** parameter. A special value of 0xFFFFFFFF (-1) can be used to specify the last message in the mailbox.

dwMessageFlags

This parameter is used to determine which messages are enumerated. If the value is zero, then all messages in the mailbox will be enumerated. If the value is non-zero, only those messages which have at least one of the specified flags will be returned. The following flags can be used to filter which messages are included in the result:

Value	Description
IMAP_FLAG_ANSWERED	Return only those messages which have been answered.
IMAP_FLAG_DELETED	Return only those messages which have been marked for deletion.
IMAP_FLAG_DRAFT	Return only those messages which have been marked as draft copies.
IMAP_FLAG_URGENT	Return only those messages which have been flagged for urgent or special attention.
IMAP_FLAG_RECENT	Return only those messages which have been recently added to the mailbox.
IMAP_FLAG_SEEN	Return only those messages which have been read.

lpSequenceIdList

A pointer to an array of unsigned integers that will receive the message sequence numbers for each enumerated message. The message sequence numbers are what most methods use to specify a message in the current mailbox. These values should never be stored by your application. This parameter must not be NULL.

lpMessageUidList

A pointer to an array of unsigned integers that will receive the message UIDs corresponding to the messages in the sequence. The message UIDs are unique values which persist across multiple client sessions. These values can be stored by your application and then mapped to their corresponding sequential message ID. This parameter must not be NULL.

nMaxMessages

An integer value which specifies the maximum size of both arrays. This value cannot be zero.

Return Value

If the method succeeds, the return value is the number of entities populated in both the *lpSequenceIdList* and *lpMessageUidList* arrays. If no messages match the specified criteria, the method will return a value of zero. If an error is encountered, the method returns IMAP_ERROR. To get extended error information, call the **GetLastError** method.

Remarks

The **EnumMessageUids** method retrieves a list of messages in the specified range and populates parallel arrays with each message's sequence number and corresponding unique identifier (UID). This enables applications to correlate transient message numbers with persistent UIDs for more reliable tracking across sessions. The *lpSequenceIdList* and *lpMessageUidList* arrays must be the same size, and both must be large enough to store the number of values specified by the *nMaxMessages* parameter. Both the sequential and unique message IDs are unsigned integer values, but they cannot be used interchangeably. Note that methods such as **GetMessage** and **DeleteMessage** expect sequential message numbers, not message UIDs.

If your application stores the message UIDs to maintain some persistent information about the mailbox, this method will enable you to lookup those message UIDs and find the corresponding sequential message number. In most cases, you would want to call this method immediately after calling **SelectMailbox**. This will cause the client to request a list of message UIDs in the selected mailbox within the range that you specify. Mailboxes with a very large number of messages may cause the application to block for an extended period of time while the list is returned and processed.

To map all messages in the selected mailbox, set `nFirstMessageId = 1`, `nLastMessageId = (UINT)-1` and `dwMessageFlags = 0`.

If the message UID is being stored locally by the client to identify the message over multiple sessions, it must also store the mailbox UID. Only the combination of the mailbox name, mailbox UID and message UID can be used to uniquely identify a given message on the server. Although IMAP server implementations are encouraged to maintain persistent message UIDs, they are not required to do so. Message UIDs may change if the mailbox is recreated or its unique identifier (UIDVALIDITY) is reset.

In some cases, particularly with newly created or infrequently used mailboxes, the message sequence numbers may *coincidentally* match the UIDs assigned by the server. For example, the first message in a new mailbox might have both a message sequence number and UID of 1. However, this is not guaranteed, and applications should never assume that sequence numbers and UIDs are interchangeable. Sequence numbers are dynamic and reflect the current ordering of messages in the selected mailbox. They can change between sessions or when messages are added or deleted. UIDs, on the other hand, are intended to be persistent identifiers that remain associated with a specific

message, even if its sequence number changes.

It is important to note that a message UID is not the same as the Message-ID header field found within the message content. The UID is a unique numeric identifier assigned by the IMAP server to a message in a specific mailbox. It is used by the protocol to track messages even as their sequence numbers change due to mailbox activity (e.g.: new messages arriving or messages being deleted). In contrast, the Message-ID header is a string value generated by the sending email client when the message is created. It is part of the message headers and intended to be globally unique for email threading and deduplication purposes, but it has no direct relationship to the UID used by the server.

Example

This example demonstrates how to enumerate all messages in the currently selected mailbox and retrieve the mapping between their sequential message numbers and server-assigned UIDs. This is useful when your application needs to track messages persistently across sessions using UIDs, while still interacting with the API methods that require sequence numbers such as **GetMessage**.

```
// Get some information about the currently selected mailbox
UINT nLastMessage = 0;
DWORD dwMailboxSize = 0;
INT nMessageCount = imapClient.GetMessageCount(&nLastMessage, &dwMailboxSize);

_tprintf(_T("There are %d messages in %s (last message is %u, mailbox size is %lu
bytes)\n"),
         nMessageCount, szMailbox, nLastMessage, dwMailboxSize);

if (nMessageCount < 1)
{
    // There are no messages in the current mailbox
    return;
}

// Allocate memory for the array of sequence numbers and UIDs
UINT *pSeqList = new UINT[nMessageCount];
UINT *pUidList = new UINT[nMessageCount];

// Populate the arrays with message sequence numbers and corresponding UIDs
INT nUidCount = imapClient.EnumMessageUids(pSeqList, pUidList, nMessageCount);

if (nUidCount > 0 && nUidCount <= nMessageCount)
{
    // Display the mapping of message sequence numbers to UIDs
    for (INT nIndex = 0; nIndex < nUidCount; nIndex++)
    {
        _tprintf(_T("\tMessage %u was assigned UID %u\n"), pSeqList[nIndex],
pUidList[nIndex]);
    }
}
else
{
    // Enumeration failed or no matching messages
    DWORD dwError = imapClient.GetLastError();
    _tprintf(_T("Unable to enumerate message UIDs (error code: 0x%lx)\n"),
dwError);
}

// Free the memory allocated for our arrays
delete[] pSeqList;
delete[] pUidList;
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

CImapClient::ExamineMailbox Method

```
INT ExamineMailbox(
   LPCTSTR lpszMailbox,
   LPIMAPMAILBOX lpMailboxInfo
);
```

The **ExamineMailbox** method selects the specified mailbox for read-only access.

Parameters

lpszMailbox

A null-terminated string which specifies the new mailbox to be examined.

lpMailboxInfo

A pointer to an IMAPMAILBOX structure which contains information about the mailbox when the method returns. This parameter may be NULL if the caller does not require any information about the mailbox.

Return Value

If the method succeeds, it returns zero. If an error occurs, the method returns IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **ExamineMailbox** method is used to select a mailbox in read-only mode. Messages can be read, but they cannot be modified or deleted from the mailbox and new messages will not lose their status as new messages if they are accessed.

If the client has a different mailbox currently selected, that mailbox will be closed and any messages marked for deletion will be expunged. To prevent deleted messages from being removed from the previous mailbox, use the **UnselectMailbox** method prior to examining the new mailbox.

If an application wishes to update the information returned in the IMAPMAILBOX structure for the current mailbox, simply call **ExamineMailbox** again with the same mailbox name.

The special case-insensitive mailbox name INBOX is used for new messages. Other mailbox names may or may not be case-sensitive depending on the IMAP server's operating system and implementation.

To access a mailbox in read-write mode, use the **SelectMailbox** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CImapClient::ExpungeMailbox Method

```
INT ExpungeMailbox(
   LPIMAPMAILBOX lpMailboxInfo
);
```

The **ExpungeMailbox** method removes all messages marked for deletion from the current mailbox.

Parameters

lpMailboxInfo

A pointer to an IMAPMAILBOX structure which contains information about the mailbox when the method returns. This parameter may be NULL if the caller does not require any information about the mailbox.

Return Value

If the method succeeds, it returns zero. If an error occurs, the method returns IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **ExpungeMailbox** method causes all messages marked for deletion to be removed from the mailbox. Note that this can cause the mailbox's UID to change, and potentially invalidate the current message UIDs. It is recommended that applications use the information returned in the IMAPMAILBOX structure to update any internal state information stored on the local system.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

CImapClient::FreezeEvents Method

```
INT FreezeEvents(
   BOOL bFreeze
);
```

The **FreezeEvents** method is used to suspend and resume event handling by the client.

Parameters

bFreeze

A non-zero value specifies that event handling should be suspended by the client. A zero value specifies that event handling should be resumed.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

This method should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all client events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if the client has suspended event handling, and four read events occur, once event handling is resumed only one of those read events will be posted to the client. This prevents the application from being flooded by a potentially large number of queued events.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

CImapClient::GetCapability Method

```
INT GetCapability(
   LPTSTR lpszCapability,
   INT nMaxLength
);

INT GetCapability(
   CString& strCapability
);
```

The **GetCapability** method returns a string which identifies the capabilities of the IMAP server.

Parameters

lpszCapability

A null-terminated string buffer that will contain one or more tokens separated by spaces which identify the capabilities of the IMAP server.

nMaxLength

The maximum length of the capability string, including the terminating null character.

Return Value

If the function succeeds, it returns the length of the capability string, not including the terminating null character. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

This method returns a string that contains one or more tokens separated by whitespace. Each token identifies a capability of the server. The following table lists some of the common capabilities:

Capability	Description
ACL	The RFC 2086 ACL extension
BINARY	The RFC 3516 binary content extension
CHILDREN	The RFC 3348 child mailbox extension
ID	The RFC 2971 ID extension
IDLE	The RFC 2177 IDLE extension
LOGINDISABLED	The RFC 2595 TLS/SSL extension
LOGINREFERRALS	The RFC 2221 login referrals extension
MAILBOXREFERRALS	The RFC 2193 mailbox referrals extension
MULTIAPPEND	The RFC 3501 MULTIAPPEND extension
NAMESPACE	The RFC 2342 namespace Extension
QUOTA	The RFC 2087 QUOTA extension
STARTTLS	The RFC 2595 TLS/SSL extension
UNSELECT	The RFC 3691 UNSELECT extension

Additional capabilities may be supported by your server. Note that experimental or custom capabilities

are always prefixed with the letter X. A list of standard IMAP capabilities is maintained by the Internet Assigned Numbers Authority (IANA) at www.iana.org.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

CImapClient::GetCurrentMailbox Method

```
INT GetCurrentMailbox(
   LPTSTR lpszMailbox,
   INT nMaxLength
);

INT GetCurrentMailbox(
   CString& strMailbox
);
```

The **GetCurrentMailbox** method returns the name of the current mailbox that has been selected.

Parameters

lpszMailbox

A null-terminated string buffer that will contain the current mailbox name. If the application uses the Unicode character set, the mailbox name will automatically be converted from modified UTF-7 encoding to Unicode. If the application does not use Unicode, the mailbox name will be returned using modified UTF-7 encoding. An alternate form of the method accepts a **CString** object which will contain the mailbox name when the method returns.

nMaxLength

The maximum length of the mailbox string, including the terminating null character.

Return Value

If the method succeeds, it returns the length of the current mailbox name, not including the terminating null character. If an error occurs, the method returns IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

It is recommended you compile the application using the Unicode character set, particularly if it is possible that mailbox names will contain Unicode characters or symbols. This will ensure that mailbox names are automatically converted from modified UTF-7 to UTF-16 Unicode. If Unicode is not used and a mailbox name contains non-ASCII characters, the name will be returned using a modified UTF-7 encoding format as defined by the IMAP4 standard. The mailbox name will not be returned as UTF-8 Unicode or as ANSI text converted to the current locale.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

CImapClient::GetDeletedMessages Method

```
INT GetDeletedMessages(
   UINT *lpnMessageIds,
   INT nMaxMessages
);
```

The **GetDeletedMessages** method returns the message identifiers for those messages that have been marked for deletion in the current mailbox.

Parameters

lpnMessageIds

A pointer to an array of unsigned integers that will contain the message identifiers of those messages which have been marked for deletion in the current mailbox. This parameter may be NULL, in which case the method will return the number of deleted messages but will not return their identifiers.

nMaxMessages

The maximum number of message identifiers that may be stored in the ***lpnMessageIds*** array. If the ***lpnMessageIds*** parameter is NULL, this value should be zero.

Return Value

If the method succeeds, the return value is the number of messages marked for deletion in the current mailbox. If the method fails, the return value is IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The message identifiers returned by this method are only valid until the mailbox is expunged or another mailbox is selected.

To remove the deleted flag from a message, use the **UndeleteMessage** method. To prevent all messages in the current mailbox from being expunged, use the **ReselectMailbox** method to reset the current mailbox state.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

CImapClient::GetErrorString Method

```
INT GetErrorString(
   DWORD dwErrorCode,
   LPTSTR lpszDescription,
   INT nMaxLength
);

INT GetErrorString(
   DWORD dwErrorCode,
   CString& strDescription
);
```

The **GetErrorString** method is used to return a description of a specific error code. Typically this is used in conjunction with the **GetLastError** method for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

The buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length. An alternate form of the method accepts a **CString** variable which will contain the error description.

nMaxLength

The maximum number of characters that may be copied into the description buffer.

Return Value

If the method succeeds, the return value is the length of the description string. If the method fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the method is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetLastError, SetLastError, ShowError

CImapClient::GetFirstMailbox Method

```
INT GetFirstMailbox(
   LPCTSTR lpszReference,
   LPCTSTR lpszWildcard,
   DWORD dwOptions,
   LPTSTR lpszMailbox,
   INT nMaxLength
   LPDWORD lpdwFlags
);

INT GetFirstMailbox(
   CString& strMailbox,
   LPDWORD lpdwFlags
);
```

The **GetFirstMailbox** method returns the name of the first matching mailbox.

Parameters

lpszReference

A null-terminated string which specifies the reference name. An empty string or NULL pointer specifies that the default mailbox hierarchy for the current user is returned. If the reference name is provided, this must be the name of a mailbox or a level of the mailbox hierarchy which provides the context in which the mailbox name is interpreted.

lpszWildcard

A null-terminated string which specifies the mailbox name to match. The wildcard character "*" may be used to match any portion of the mailbox hierarchy, including the delimiter. The wildcard character "%" matches any portion of the mailbox name, but does not match the mailbox delimiter. An empty string or NULL pointer specifies that all mailboxes in the context of the *lpszReference* parameter should be returned.

dwOptions

Specifies one or more options which controls how mailboxes are returned by the method. The options are bit flags which may be combined using a bitwise operator. One or more of the following values may be used:

Value	Description
IMAP_LIST_DEFAULT	This option specifies that all regular, selectable mailboxes should be returned.
IMAP_LIST_SUBSCRIBED	This option specifies that only subscribed mailboxes should be returned.
IMAP_LIST_FOLDERS	This option specifies that non-selectable mailbox folders should also be returned.
IMAP_LIST_HIDDEN	This option specifies that hidden mailboxes should be returned.
IMAP_LIST_INFERIOR	This option specifies that inferior mailboxes should be returned if an explicit wildcard mask is not specified.

lpszMailbox

A null-terminated string buffer which will contain the first matching mailbox. This parameter cannot

be NULL. A minimum buffer size of at least 128 character is recommended. If the application uses the Unicode character set, the mailbox name will automatically be converted from modified UTF-7 encoding to Unicode. If the application does not use Unicode, the mailbox name will be returned using modified UTF-7 encoding.

nMaxLength

Specifies the maximum length of the string buffer. The maximum length of the buffer should be large enough to accommodate most path names on the IMAP server.

lpdwFlags

A pointer to an unsigned integer which will contain the mailbox flags for the first matching mailbox. This parameter may be NULL, in which case the mailbox flags are not returned. Otherwise, one or more of the following bit flags may be returned:

Value	Description
IMAP_FLAG_NOINFERIORS	The mailbox does not contain any sub-mailboxes. In the IMAP protocol, these are referred to as inferior hierarchical mailbox names.
IMAP_FLAG_NOSELECT	The mailbox cannot be selected or examined. This flag is typically used by servers to indicate that the mailbox name refers to a directory on the server, not a mailbox file.
IMAP_FLAG_MARKED	The mailbox is marked as being of interest to a client. If this flag is used, it typically means that the mailbox contains messages. An application should not depend on this flag being present for any given mailbox. Some IMAP servers do not support marked or unmarked flags for mailboxes.
IMAP_FLAG_UNMARKED	The mailbox is marked as not being of interest to a client. If this flag is used, it typically means that the mailbox does not contain any messages. An application should not depend on this flag being present for any given mailbox. Some IMAP servers do not support marked or unmarked flags for mailboxes.

Return Value

If the method succeeds, it returns the length of the mailbox name. If an error occurs, the method returns IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetFirstMailbox** method is used to begin enumerating the available mailboxes for the current user on the IMAP server. Subsequent mailbox names are returned by calling **GetNextMailbox** until the method returns IMAP_ERROR with an error code of ST_ERROR_NO_MORE_MAILBOXES.

It is recommended you compile the application using the Unicode character set, particularly if it is possible that mailbox names will contain Unicode characters or symbols. This will ensure that mailbox names are automatically converted from modified UTF-7 to UTF-16 Unicode. If Unicode is not used and a mailbox name contains non-ASCII characters, the name will be returned using a modified UTF-7 encoding format as defined by the IMAP4 standard. The mailbox name will not be returned as UTF-8 Unicode or as ANSI text converted to the current locale.

The method of the ***lpszReference*** and ***lpszWildcard*** parameters are implementation dependent and generally are tied to the underlying operating system. On a UNIX based system, it can be helpful to

think of the reference name as the directory where mailbox folders are stored, and the mailbox name as the name to search for in that directory and any subdirectories, if applicable. If the reference name is an empty string or NULL pointer, this typically refers to the current user's home directory.

Generally speaking, a reference name should only be specified if you or the user of the application knows the directory structure on the IMAP server. Incorrectly using a reference name can have serious negative side-effects. For example, specifying a reference name of "/" on a UNIX based system could cause the IMAP server to return search every directory on the system for a matching mailbox name. Similarly, the IMAP server may be unable to distinguish between regular files in the user's home directory and mailboxes. For this reason, most IMAP clients require that the user specify the directory on the server where their mailboxes are stored. Typically this is subdirectory named "mail" or "Mail" under the user's home directory. For non-UNIX servers, the mailbox hierarchy may represented differently, including a flat hierarchy.

Hidden mailboxes are those mailboxes which use the UNIX convention of the name beginning with a period. Therefore, a mailbox named ".secrets" would not normally be returned by the **GetFirstMailbox** and **GetNextMailbox** methods. The IMAP_LIST_HIDDEN option causes all mailboxes to be returned.

The IMAP_LIST_INFERIOR option will return inferior mailboxes (mailboxes located in folders or subdirectories) if a wildcard mask is not specified. If a wildcard mask is specified, this option has no effect and only those mailboxes which match the wildcard will be returned.

Subscribed mailboxes are those which were specified using the **SubscribeMailbox** method. Marked mailboxes are typically those which have some special importance to the user.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

CImapClient::GetHandle Method

```
HCLIENT GetHandle();
```

The **GetHandle** method returns the client handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the client handle associated with the current instance of the class object. If there is no active client session, the value INVALID_CLIENT will be returned.

Remarks

This method is used to obtain the client handle created by the class for use with the SocketTools API.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

See Also

AttachHandle, DetachHandle, IsInitialized

CImapClient::GetHeaderValue Method

```
INT GetHeaderValue(
   UINT nMessageId,
   UINT nMessagePart,
   LPCTSTR lpszHeader,
   LPTSTR lpszValue,
   INT nMaxLength
);

INT GetHeaderValue(
   UINT nMessageId,
   LPCTSTR lpszHeader,
   LPTSTR lpszValue,
   INT nMaxLength
);

INT GetHeaderValue(
   UINT nMessageId,
   UINT nMessagePart,
   LPCTSTR lpszHeader,
   CString& strValue
);

INT GetHeaderValue(
   UINT nMessageId,
   LPCTSTR lpszHeader,
   CString& strValue
);
```

The **GetHeaderValue** method returns the value of a header field in the specified message.

Parameters

nMessageId

Number of message to retrieve header value from. This value must be greater than zero. The first message in the mailbox is message number one.

nMessagePart

The message part that the header value will be be retrieved from. Message parts start with a value of one. A value of zero specifies that the RFC822 header field for the message will be used.

lpszHeader

Pointer to a string which specifies the message header to retrieve. The colon should not be included in this string.

lpszValue

Pointer to a string buffer that will contain the value of the specified message header.

nMaxLength

The maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the method succeeds, it returns the length of the header field value. If the header field is not present in the message, the method will return a value of zero. If the method fails, the return value is

IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetHeaderValue** method returns the value of header field from the specified message. This allows an application to be able to easily determine the value of a header such as the sender, or the subject of the message. Any header field, including non-standard extensions, may be returned by this method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

CImapClient::GetIdleThreadId Method

```
DWORD GetIdleThreadId();
```

The **GetIdleThreadId** method returns ID of the thread that is monitoring the client session.

Parameters

None.

Return Value

If the method succeeds, it returns the ID of the thread that is checking for update notifications from the server. If there is no active thread monitoring the client session, the method will return zero.

Remarks

The worker thread that monitors the client connection in the background can terminate if an IMAP command is sent to the server, if the **Cancel** method is called or if the client disconnects from the server. The **GetIdleThreadId** method enables the application to determine if this background thread is still active or not.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

CImapClient::GetLastError Method

```
DWORD GetLastError();

DWORD GetLastError(
   CString& strDescription
);
```

Parameters

strDescription

A string which will contain a description of the last error code value when the method returns. If no error has been set, or the last error code has been cleared, this string will be empty.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **SetLastError** method. The Return Value section of each reference page notes the conditions under which the method sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **GetLastError** method immediately when a method's return value indicates that an error has occurred. That is because some methods call **SetLastError**(0) when they succeed, clearing the error code set by the most recently failed method.

Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or IMAP_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

The description of the error code is the same string that is returned by the **GetErrorString** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

See Also

CImapClient::GetMailboxDelimiter Method

```
INT GetMailboxDelimiter(
   LPCTSTR lpszMailbox,
   LPTSTR lpszDelimiter,
   INT nMaxLength
);

INT GetMailboxDelimiter(
   LPCTSTR lpszMailbox,
   CString& strDelimiter
);
```

The **GetMailboxDelimiter** method returns the hierarchical path delimiter used for the specified mailbox.

Parameters

lpszMailbox

A null-terminated string which specifies the mailbox name. This parameter may be NULL or an empty string, in which case the default delimiter will be returned.

lpszDelimiter

A null-terminated string buffer that will contain the mailbox delimiter. An alternate form of this method accepts a **CString** object that will contain the delimiter when the method returns.

nMaxLength

The maximum length of the delimiter string, including the terminating null character.

Return Value

If the method succeeds, it returns the length of the delimiter for the specified mailbox, not including the terminating null character. If an error occurs, the method returns IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

If the IMAP server supports multiple levels of mailboxes, then a special character or sequence of characters are used as delimiters between different levels of the mailbox hierarchy. On most systems, including most UNIX and Windows platforms, the delimiter is the forward slash "/" character.

It is possible that an IMAP server may only support a flat namespace, in which case this method will return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

CImapClient::GetMailboxSize Method

```
DWORD GetMailboxSize(
   LPCTSTR lpszMailbox
);
```

The **GetMailboxSize** method returns the size of the specified mailbox.

Parameters

lpszMailbox

A null-terminated string which specifies the mailbox name.

Return Value

If the method succeeds, it returns the size of the mailbox. If an error occurs, the method returns IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetMailboxSize** method may require a significant amount of time to calculate the mailbox size if there are a large number of messages in the mailbox. If the specified mailbox is not currently selected, then the current mailbox is unselected, the new mailbox is selected and the size calculated, and then the original mailbox is re-selected. This will have the side-effect of causing any messages marked for deletion to be expunged from the mailbox.

Because it can potentially result in long delays, it is not recommended that an application calculate the mailbox size unless it is absolutely necessary.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CImapClient::GetMailboxStatus Method

```
INT GetMailboxStatus(
   LPCTSTR lpszMailbox,
   LPIMAPMAILBOXSTATUS lpMailboxStatus
);
```

The **GetMailboxStatus** method returns status information about the specified mailbox.

Parameters

lpszMailbox

A null-terminated string that specifies the mailbox to return information about.

lpMailboxStatus

A pointer to an IMAPMAILBOXSTATUS structure which contains status information about the specified mailbox.

Return Value

If the method succeeds, it returns zero. If an error occurs, the method method returns IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetMailboxStatus** method enables an application to obtain status information about a mailbox without having to select another mailbox or open a second connection to the IMAP server to examine the mailbox. The information returned is a subset of the information returned when a mailbox is selected.

If you need to check the status of a mailbox which contains Unicode characters or symbols, it is recommended you use the Unicode character set when compiling your application. The mailbox name will automatically be converted to modified UTF-7 encoding as defined by the IMAP4 standard. If you do not use Unicode, this method will only accept mailbox names using modified UTF-7 encoding or UTF-8 encoding.

Note that obtaining status information for a mailbox may be a slow operation. It may require that server open the mailbox in read-only mode internally in order to obtain some of the status information. For this reason, this method should not be used to check for new messages; use the **CheckMailbox** method instead.

Some IMAP servers may return an error if you attempt to obtain status information about the currently selected mailbox. The protocol standard states that clients should not use this method on the currently selected mailbox, and should instead use the information returned by the **SelectMailbox** or **ExamineMailbox** methods.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

CheckMailbox, ExamineMailbox, SelectMailbox

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CImapClient::GetMailboxUID Method

```
DWORD GetMailboxUID(
   LPCTSTR lpszMailbox
);
```

The **GetMailboxUID** method returns the unique identifier for the specified mailbox.

Parameters

lpszMailbox

A null-terminated string that specifies the mailbox name.

Return Value

If the method succeeds, it returns a non-zero value. If no unique identifier is assigned to the mailbox, the method will return zero. If an error occurs, the method returns IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetMailboxUID** method returns an unsigned 32-bit value which uniquely identifies the mailbox and corresponds to the UIDVALIDITY value returned by the IMAP server. The actual value is determined by the server and should be considered opaque. The protocol specification requires that a mailbox's UID must not change unless the mailbox contents are modified or existing messages in the mailbox have been assigned new UIDs.

An application can use the mailbox UID value in combination with the message UID in order to uniquely identify a message on the server. However, the application must take into consideration that the IMAP server can reassign new message UIDs when the mailbox is modified. If the mailbox and message UIDs are being stored on the local system to track what messages have been retrieved from the server, the application must check the UID of the mailbox whenever it is selected. If the mailbox UID has changed, this means that the UIDs for the messages in that mailbox may have changed. The client should resynchronize with the server, and update it's local copy of that mailbox.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

CImapClient::GetMessage Method

```
INT GetMessage(
   UINT nMessageId,
   UINT nMessagePart,
   LPBYTE lpMessage,
   LPDWORD lpdwLength,
   DWORD dwOptions
);

INT GetMessage(
   UINT nMessageId,
   UINT nMessagePart,
   HGLOBAL *lpMessage,
   LPDWORD lpdwLength,
   DWORD dwOptions
);

INT GetMessage(
   UINT nMessageId,
   UINT nMessagePart,
   CString& strMessage,
   DWORD dwOptions
);

INT GetMessage(
   UINT nMessageId,
   CString& strMessage
);
```

The **GetMessage** method retrieves a message from the server.

Parameters

nMessageId

Number of message to retrieve from the server. This value must be greater than zero. The first message in the mailbox is message number one.

nMessagePart

The message part that will be retrieved. A value of zero specifies that the complete message should be returned. If the message is a multipart MIME message, message parts start with a value of one.

lpMessage

A buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the method returns.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the ***lpMessage*** parameter. If the ***lpMessage*** parameter points to a global memory handle, the length value should be initialized to zero. When the method returns, this value will be updated with the actual length of the message that was downloaded.

dwOptions

An unsigned integer value which specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description

IMAP_SECTION_DEFAULT	All headers and the complete body of the specified message or message part are to be retrieved. The client application is responsible for parsing the header block. If the message is a MIME multipart message and the complete message is returned, the application is responsible for parsing the individual message parts if necessary.
IMAP_SECTION_HEADER	All headers for the specified message or message part are to be retrieved. The client application is responsible for parsing the header block.
IMAP_SECTION_MIMEHEADER	The MIME headers for the specified message or message are to be retrieved. Only those header fields which are used in MIME messages, such as Content-Type will be returned to the client. This is typically useful when processing the header for a multipart message which contains file attachments. The client application is responsible for parsing the header block.
IMAP_SECTION_BODY	The body of the specified message or message part is to be retrieved. For a MIME formatted message, this may include data that is uuencoded or base64 encoded. The application is responsible for decoding this data.
IMAP_SECTION_PREVIEW	The message header or body is being previewed and should not be marked as read by the server. This prevents the message from having the IMAP_FLAG_SEEN flag from being automatically set when the message data is retrieved.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetMessage** method is used to retrieve a message from the server and copy it into a local buffer. The method may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the contents of the message. In this case, the *lpMessage* parameter will point to the buffer that was allocated, the value that the *lpdwLength* parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the *lpMessage* parameter point to a global memory handle which will contain the message data when the method returns. In this case, the value that the *lpdwLength* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the method must be freed by the application, otherwise a memory leak will occur.

This method will cause the current thread to block until the transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the IMAP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **EnableEvents**, or by registering a callback function using the **RegisterEvent** method.

To determine if a message is a multipart MIME message, use the **GetMessageParts** method. The return value specifies the number of parts in the message, with a value greater than one indicating that it is a multipart message. Combining the IMAP_SECTION_HEADER and IMAP_SECTION_BODY options will only return the header and body for the specified message if the ***nMessagePart*** parameter is zero. Due to a limitation of the IMAP FETCH command, if a message part is specified then only the body of that message part will be returned.

Note that unlike the SocketTools MIME API which considers the first message part to be zero, the IMAP protocol defines the first message part to be one.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

See Also

GetMessageCount, GetMessageHeaders, GetMessageParts, StoreMessage

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CImapClient::GetMessageCount Method

```
INT GetMessageCount(
   UINT *lpnLastMessage,
   DWORD *lpdwMailboxSize
);
```

The **GetMessageCount** method returns the number of messages that are available in the currently selected mailbox, and optionally the size of the mailbox in bytes.

Parameters

lpnLastMessage

Address of a variable that receives the number of the last valid message in the mailbox. If a NULL value is specified, this argument is ignored.

lpdwMailboxSize

Address of a variable that receives the current size of the mailbox. If a NULL value is specified, this argument is ignored.

Return Value

If the method succeeds, it returns the number of messages that are currently available. If no messages are available, this method will return zero. If the method fails, the return value is IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetMessageCount** method is provided for compatibility with the POP3 class. The *lpnLastMessage* parameter will always contain the same value returned by the method since there is no distinction between the message count and the last available message. This is because messages that are marked for deletion on an IMAP server can still be accessed until the mailbox is expunged or unselected. This differs from the POP3 protocol, where messages cannot be accessed once they have been marked for deletion.

If the *lpdwMailboxSize* parameter is specified, this method will call **GetMailboxSize** to determine the size of the currently selected mailbox. Unlike the POP3 protocol, calculating the mailbox size may require a significant amount of time if there are a large number of messages in the mailbox. It is not recommended that an application request the mailbox size unless it is absolutely necessary.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

CImapClient::GetMessageFlags Method

```
BOOL GetMessageFlags(
   UINT nMessageId,
   LPDWORD lpdwMessageFlags
);
```

The **GetMessageFlags** method returns the message flags for the specified message.

Parameters

nMessageId

Number of message to obtain the message flags for. This value must be greater than zero. The first message in the mailbox is message number one.

lpdwMessageFlags

Pointer to an unsigned integer that will contain the message flags for the specified message. The value may be zero, or one or more of the following values:

Value	Description
IMAP_FLAG_ANSWERED	The message has been answered.
IMAP_FLAG_DELETED	The message has been marked for deletion.
IMAP_FLAG_DRAFT	The message has not been completed and is marked as a draft copy.
IMAP_FLAG_URGENT	The message has been flagged for urgent or special attention.
IMAP_FLAG_RECENT	The message has been added to the mailbox recently.
IMAP_FLAG_SEEN	The message has been read.

Return Value

If the method succeeds, the return value is non-zero and the ***lpdwMessageFlags*** parameter contains the status flags for the specified message. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

CImapClient::GetMessageHeaders Method

```
INT GetMessageHeaders(
   UINT nMessageId,
   LPBYTE lpHeaders,
   LPDWORD lpdwLength
);

INT GetMessageHeaders(
   UINT nMessageId,
   HGLOBAL *lpHeaders,
   LPDWORD lpdwLength
);

INT GetMessageHeaders(
   UINT nMessageId,
   CString& strHeaders
);
```

The **GetMessageHeaders** method retrieves the headers for the specified message from the server.

Parameters

nMessageId

Number of message to retrieve from the server. This value must be greater than zero. The first message in the mailbox is message number one.

lpHeaders

A buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the method returns.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the ***lpHeaders*** parameter. If the ***lpHeaders*** parameter points to a global memory handle, the length value should be initialized to zero. When the method returns, this value will be updated with the actual length of the message that was downloaded.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetMessagHeaders** method is used to retrieve a message header block from the server and copy it into a local buffer. The method may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the contents of the file. In this case, the ***lpHeaders*** parameter will point to the buffer that was allocated, the value that the ***lpdwLength*** parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the ***lpHeaders*** parameter point to a global memory handle which will contain the file data when the method returns. In this case, the value that the ***lpdwLength*** parameter points to must be initialized to zero. It is important to note that the memory handle returned by the method must be freed by the application, otherwise a memory leak will occur.

This method will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the IMAP_EVENT_PROGRESS event will be periodically

fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **EnableEvents**, or by registering a callback function using the **RegisterEvent** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

See Also

CImapClient::GetMessageId Method

```
INT GetMessageId(
   UINT nMessageId,
   LPTSTR lpszMessageId,
   INT nMaxLength
);

INT GetMessageId(
   UINT nMessageId,
   CString& strMessageId
);
```

The **GetMessageId** method returns the message identifier string for the specified message.

Parameters

nMessageId

Number of message to retrieve the unique identifier for. This value must be greater than zero. The first message in the mailbox is message number one.

lpszMessageId

Address of a string buffer to receive the message identifier. This should be at least 64 bytes in length.

nMaxLength

The maximum length of the string buffer.

Return Value

If the method succeeds, the return value is the length of the unique identifier string. If the method fails, the return value is IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetMessageId** method returns the message identifier from the Message-ID header of the specified message. The returned value is a string which can be used to identify a specific message, regardless if the message is moved to a different mailbox.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CImapClient::GetMessageParts Method

```
INT GetMessageParts(
   UINT nMessageId
);
```

The **GetMessageParts** method returns the number of parts in a MIME multipart message on the server.

Parameters

nMessageId

Number of message to retrieve the part count for. This value must be greater than zero. The first message in the mailbox is message number one.

Return Value

If the method succeeds, the return value is the number of parts in the specified message. If the method fails, the return value is IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetMessageParts** method can be used to determine if a message on the server contains multiple parts. A multipart MIME message typically contains file attachments or multiple representations of the message, such as a version of the message in plain text and another using HTML markup.

If the method returns a value of one, then the message does not contain multiple parts and is a standard RFC822 formatted message. A value greater than one indicates that the message does have multiple parts. The **GetMessageEx** method may be used to retrieve the data for a specific part of the message.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

CImapClient::GetMessageSender Method

```
INT GetMessageSender(
   UINT nMessageId,
   LPTSTR lpszAddress,
   INT nMaxLength
);

INT GetMessageSender(
   UINT nMessageId,
   CString& strAddress
);
```

The **GetMessageSender** method returns the sender's address for the specified message.

Parameters

nMessageId

Number of message to retrieve header value from. This value must be greater than zero. The first message in the mailbox is message number one.

lpszAddress

Pointer to a string buffer that will contain the address of the message sender.

nMaxLength

The maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the method succeeds, it returns the length of the address. If the sender cannot be determined, the method will return a value of zero. If the method fails, the return value is IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetMessageSender** method returns the email address specified in the Return-Path header field. This allows an application to be able to easily determine the sender, without parsing the header or downloading the contents of the message.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

CImapClient::GetMessageUID Method

```
DWORD GetMessageUID(
   UINT nMessageId
);
```

The **GetMessageUID** method returns the unique identifier (UID) for the specified message in the current mailbox.

Parameters

nMessageId

Number of message to obtain the unique identifier for. This value must be greater than zero. The first message in the mailbox is message number one.

Return Value

If the method succeeds, it returns a non-zero value. If no unique identifier is assigned to the message, the method will return zero. If an error occurs, the method returns IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetMessageUID** method returns an unsigned integer value which specifies a unique identifier for this message. The actual value is determined by the server and should be considered opaque.

An application can use the message UID value in combination with the mailbox UID in order to uniquely identify a message on the server. However, the application must take into consideration that the IMAP server can reassign new message UIDs when the mailbox is modified. If the mailbox and message UIDs are being stored on the local system to track what messages have been retrieved from the server, the application must check the UID of the mailbox whenever it is selected. If the mailbox UID has changed, this means that the UIDs for the messages in that mailbox may have changed. The client should resynchronize with the server, and update it's local copy of that mailbox.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

CImapClient::GetNewMessages Method

```
INT GetNewMessages(
   UINT *lpnMessageIds,
   INT nMaxMessages
);
```

The **GetNewMessages** method returns the message identifiers for those messages that have recently been added to the mailbox and have not been read.

Parameters

lpnMessageIds

A pointer to an array of unsigned integers that will contain the message identifiers of those messages that have recently been added to the mailbox and have not been read. This parameter may be NULL, in which case the method will return the number of new messages but will not return their identifiers.

nMaxMessages

The maximum number of message identifiers that may be stored in the ***lpnMessageIds*** array. If the ***lpnMessageIds*** parameter is NULL, this value should be zero.

Return Value

If the method succeeds, the return value is the number of new messages in the current mailbox. If the method fails, the return value is IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The message identifiers returned by this method are only valid until the mailbox is expunged or another mailbox is selected. Once a message has been read using **GetMessage** or **StoreMessage**, it is no longer considered to be a new message.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

See Also

GetDeletedMessages, GetMessageCount, GetMessageFlags, GetUnseenMessages, SearchMailbox

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CImapClient::GetNextMailbox Method

```
INT GetNextMailbox(
   LPTSTR lpszMailbox,
   INT nMaxLength
   LPDWORD lpdwFlags
);

INT GetNextMailbox(
   CString& strMailbox,
   LPDWORD lpdwFlags
);
```

The **GetNextMailbox** method returns the name of the next matching mailbox.

Parameters

lpszMailbox

A null-terminated string buffer which will contain the next matching mailbox. This parameter cannot be NULL. A minimum buffer size of at least 128 character is recommended. If the application uses the Unicode character set, the mailbox name will automatically be converted from modified UTF-7 encoding to Unicode. If the application does not use Unicode, the mailbox name will be returned using modified UTF-7 encoding.

nMaxLength

Specifies the maximum length of the string buffer. The maximum length of the buffer should be large enough to accommodate most path names on the IMAP server.

lpdwFlags

A pointer to an unsigned integer which will contain the mailbox flags for the next matching mailbox. This parameter may be NULL, in which case the mailbox flags are not returned. Otherwise, one or more of the following bit flags may be returned:

Value	Description
IMAP_FLAG_NOINFERIORS	The mailbox does not contain any sub-mailboxes. In the IMAP protocol, these are referred to as inferior hierarchical mailbox names.
IMAP_FLAG_NOSELECT	The mailbox cannot be selected or examined. This flag is typically used by servers to indicate that the mailbox name refers to a directory on the server, not a mailbox file.
IMAP_FLAG_MARKED	The mailbox is marked as being of interest to a client. If this flag is used, it typically means that the mailbox contains messages. An application should not depend on this flag being present for any given mailbox. Some IMAP servers do not support marked or unmarked flags for mailboxes.
IMAP_FLAG_UNMARKED	The mailbox is marked as not being of interest to a client. If this flag is used, it typically means that the mailbox does not contain any messages. An application should not depend on this flag being present for any given mailbox. Some IMAP servers do not support marked or unmarked flags for mailboxes.

Return Value

If the method succeeds, it returns the length of the mailbox name. If an error occurs, the method returns IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetNextMailbox** method returns the next matching mailbox name. When the last mailbox has been returned, the next call to this method will result in an error, with the last error code set to ST_ERROR_NO_MORE_MAILBOXES.

It is recommended you compile the application using the Unicode character set, particularly if it is possible that mailbox names will contain Unicode characters or symbols. This will ensure that mailbox names are automatically converted from modified UTF-7 to UTF-16 Unicode. If Unicode is not used and a mailbox name contains non-ASCII characters, the name will be returned using a modified UTF-7 encoding format as defined by the IMAP4 standard. The mailbox name will not be returned as UTF-8 Unicode or as ANSI text converted to the current locale.

Subscribed mailboxes are those which were specified using the **SubscribeMailbox** method. Marked mailboxes are typically those which have some special importance to the user.

For more information about enumerating the available mailboxes on the IMAP server, refer to the **GetFirstMailbox** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CImapClient::GetResultCode Method

```
INT GetResultCode();
```

The **GetResultCode** method reads the result code returned by the server in response to a command. The result code is a three-digit numeric code, and indicates if the operation succeeded, failed or requires additional action by the client.

Parameters

None.

Return Value

If the method succeeds, the return value is the result code. If the method fails, the return value is IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

Result codes are three-digit numeric values returned by the server. They may be broken down into the following ranges:

Value	Description
100-199	Positive preliminary result. This indicates that the requested action is being initiated, and the client should expect another reply from the server before proceeding.
200-299	Positive completion result. This indicates that the server has successfully completed the requested action.
300-399	Positive intermediate result. This indicates that the requested action cannot complete until additional information is provided to the server.
400-499	Transient negative completion result. This indicates that the requested action did not take place, but the error condition is temporary and may be attempted again.
500-599	Permanent negative completion result. This indicates that the requested action did not take place.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

Command, GetResultString

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CImapClient::GetResultString Method

```
INT GetResultString(
   LPTSTR lpszResult,
   INT cbResult
);

INT GetResultString(
   CString& strResult
);
```

The **GetResultString** method returns the last message sent by the server along with the result code.

Parameters

lpszResult

The buffer that will contain the result string returned by the server. An alternate form of the method accepts a **CString** argument which will contain the result string returned by the server.

cbResult

The maximum number of characters that may be copied into the result string buffer, including the terminating null character.

Return Value

If the method succeeds, the return value is the length of the result string. If a value of zero is returned, this means that no result string was sent by the server. If the method fails, the return value is IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetResultString** method is most useful when an error occurs because the server will typically include a brief description of the cause of the error. This can then be parsed by the application or displayed to the user. The result string is updated each time the client sends a command to the server and then calls **GetResultCode** to obtain the result code for the operation.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

CImapClient::GetStatus Method

```
INT GetStatus();
```

The **GetStatus** method the current status of the client session.

Parameters

None.

Return Value

If the method succeeds, the return value is the client status code. If the method fails, the return value is IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetStatus** method returns a numeric code which identifies the current state of the client session. The following values may be returned:

Value	Description
IMAP_STATUS_UNUSED	No connection has been established.
IMAP_STATUS_IDLE	The client is current idle and not sending or receiving data.
IMAP_STATUS_CONNECT	The client is establishing a connection with the server.
IMAP_STATUS_READ	The client is reading data from the server.
IMAP_STATUS_WRITE	The client is writing data to the server.
IMAP_STATUS_DISCONNECT	The client is disconnecting from the server.

In a multithreaded application, any thread in the current process may call this method to obtain status information for the specified client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

CImapClient::GetSecurityInformation Method

```
BOOL GetSecurityInformation(
   LPSECURITYINFO lpSecurityInfo
);
```

The **GetSecurityInformation** method returns security protocol, encryption and certificate information about the current client connection.

Parameters

lpSecurityInfo

A pointer to a SECURITYINFO structure which contains information about the current client connection. The *dwSize* member of this structure must be initialized to the size of the structure before passing the address of the structure to this method.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method is used to obtain security related information about the current client connection to the server. It can be used to determine if a secure connection has been established, what security protocol was selected, and information about the server certificate. Note that a secure connection has not been established, the *dwProtocol* structure member will contain the value SECURITY_PROTOCOL_NONE.

Example

```
// Notifies the user if the connection is secure or not
SECURITYINFO securityInfo;
securityInfo.dwSize = sizeof(SECURITYINFO);

if (pClient->GetSecurityInformation(&securityInfo))
{
    if (securityInfo.dwProtocol == SECURITY_PROTOCOL_NONE)
    {
        MessageBox(NULL, _T("The connection is not secure"),
                         _T("Connection"), MB_OK);
    }
    else
    {
        if (securityInfo.dwCertStatus == SECURITY_CERTIFICATE_VALID)
        {
            MessageBox(NULL, _T("The connection is secure"),
                             _T("Connection"), MB_OK);
        }
        else
        {
            MessageBox(NULL, _T("The server certificate not valid"),
                             _T("Connection"), MB_OK);
        }
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

CImapClient::GetTimeout Method

```
INT GetTimeout();
```

The **GetTimeout** method returns the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the method will fail and return to the caller.

Parameters

None.

Return Value

If the method succeeds, the return value is the timeout period in seconds. If the method fails, the return value is IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The timeout value is only used with blocking client connections. A value of zero indicates that the default timeout period of 20 seconds should be used.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

CImapClient::GetTransferStatus Method

```
INT GetTransferStatus(
   LPIMAPTRANSFERSTATUS lpStatus
);
```

The **GetTransferStatus** method returns information about the current file transfer in progress.

Parameters

lpStatus

A pointer to an IMAPTRANSFERSTATUS structure which contains information about the status of the current file transfer.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetTransferStatus** method returns information about the current file transfer, including the average number of bytes transferred per second and the estimated amount of time until the transfer completes. If there is no file currently being transferred, this method will return the status of the last successful transfer made by the client.

In a multithreaded application, any thread in the current process may call this method to obtain status information for the specified client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

CImapClient::GetUnseenMessages Method

```
INT GetUnseenMessages(
   UINT *lpnMessageIds,
   INT nMaxMessages
);
```

The **GetUnseenMessages** method returns the message identifiers for those messages that have not been read.

Parameters

lpnMessageIds

A pointer to an array of unsigned integers that will contain the message identifiers of those messages that have not been read. This parameter may be NULL, in which case the method will return the number of unseen messages but will not return their identifiers.

nMaxMessages

The maximum number of message identifiers that may be stored in the ***lpnMessageIds*** array. If the ***lpnMessageIds*** parameter is NULL, this value should be zero.

Return Value

If the method succeeds, the return value is the number of unseen messages in the current mailbox. If the method fails, the return value is IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The message identifiers returned by this method are only valid until the mailbox is expunged or another mailbox is selected. Once a message has been read using **GetMessage** or **StoreMessage**, it is no longer considered to be an unseen message.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

CImapClient::Idle Method

```
INT Idle(
   IMAPIDLEPROC lpfnIdleProc,
   DWORD_PTR dwParam
);

INT Idle(
   UINT nTimeout,
   DWORD dwOptions,
   IMAPIDLEPROC lpfnIdleProc,
   DWORD_PTR dwParam
);
```

The **Idle** method enables mailbox status monitoring for the client session, allowing the client to receive notifications from the server whenever a new message arrives or a message is expunged from the currently selected mailbox. This is typically used as an alternative to the client periodically polling the server for status information.

Parameters

nTimeout

Specifies the timeout period in seconds to wait for a notification from the server. This parameter is only used when the IMAP_IDLE_WAIT option has been specified.

dwOptions

Specifies the options which should be used when enabling idle monitoring. The following options are supported:

Value	Description
IMAP_IDLE_NOWAIT	The method should return immediately after idle processing has been enabled. When this option is used, the application may continue to perform other methods while the client session is monitored for status updates sent by the server. The client will continue to monitor status changes until an IMAP command issued or the client disconnects from the server.
IMAP_IDLE_WAIT	The method should wait until the server sends a status update, or until the timeout period is reached. The client will stop monitoring status changes when the method returns. If this option is used in a single-threaded application, normal message processing can be impeded, causing the application to appear non-responsive until the timeout period is reached. It is strongly recommended that single-threaded applications with a user interface specify the IMAP_IDLE_NOWAIT option instead.

lpfnIdleProc

A pointer to an IMAPIDLEPROC callback function that will be invoked whenever the server sends an update notification to the client. This parameter must specify a valid function address and cannot be a NULL pointer.

dwParam

A user-defined value that is passed back to the caller whenever the callback function is invoked. This can be used to provide additional state information to the client. If it is not needed, the caller should

use a value of zero.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

Many IMAP servers support the ability to asynchronously send status updates to the client, rather than have the client periodically poll the server. The client enables this feature by calling **Idle** and providing the address of a callback function that will be invoked whenever the server sends an update notification to the client. Typically these updates inform the client that a new message has arrived or that a message has been expunged from the mailbox.

The **Idle** method can operate in two modes, based on the options specified by the caller. If the option IMAP_IDLE_NOWAIT is specified, the method begins monitoring the client session and returns control immediately to the caller. If the server sends a update notification, the callback function will be invoked with information about the status change. If the option IMAP_IDLE_WAIT is specified, the method will block waiting for the server to send a notification message to the client. The method will return when either a message is received or the timeout period is exceeded.

Sending an IMAP command to the server will cause the client to stop monitoring the session for status changes. To explicitly stop monitoring the session, use the **Cancel** method. To determine if the current client session is being monitored, use the **GetIdleThreadId** method. A non-zero return value indicates that the client session is idle and being monitored.

This method works by sending the IDLE command to the server and starting a worker thread which monitors the connection and looks for untagged responses issued by the server. Callbacks will be invoked for EXISTS, EXPUNGE and RECENT messages. Note that some servers may periodically send untagged OK messages to the client, indicating that the connection is still active; these messages are explicitly ignored. Because the monitoring is performed in a different thread, the callback function is invoked in the context of that thread. Client event notifications are disabled while inside the callback function, and the **Idle** method cannot be used to restart monitoring from within a callback function.

Applications should not perform any operation that takes a significant amount of time or updates the user interface from within the callback function. Instead, use flags or send application defined messages to indicate a change in state. For example, if the server sends a notification that a new email message has arrived, the application should not attempt to read the new message and update the user interface from within the callback function. Instead, it could use the **CWindow::PostMessage** method to send an application-defined message to the UI thread indicating the change in state. The application would have a message handler for that Windows message and update the user interface, indicating that a new message has arrived.

An application should never make an assumption about how a particular server may send update notifications to the client. Servers can be configured to use different intervals at which notifications are sent. For example, a server may send new message notifications immediately, but may periodically notify the client when a message has been expunged. Alternatively, a server may only send notifications at fixed intervals, in which case the client would not be notified of any new messages until the interval period is reached. It is not possible for a client to know what a particular server's update interval is. Applications that require that degree of control should not use **Idle** and should poll the server instead.

Example

```
// Begin monitoring the client session for status changes; when a new
```

```
// message arrives or a message is expunged, the UpdateHandler callback
// function will be invoked.
BOOL CUserApp::MonitorUpdates()
{
    INT nResult;

    nResult = m_imapClient.Idle(UpdateHandler, (DWORD)this);

    if (nResult == IMAP_ERROR)
    {
        m_imapClient.ShowError();
        return FALSE;
    }

    return TRUE;
}

// This function is called whenever the server notifies the client
// that a new message has arrived or a message has been expunged from
// the current mailbox
#define WM_APP_NEWMESSAGE (WM_APP+1)
#define WM_APP_EXPUNGED   (WM_APP+2)

VOID CALLBACK CUserApp::UpdateHandler(HCLIENT hClient, UINT nUpdateId, UINT
nMessageId, DWORD_PTR dwParam)
{
    CUserApp *pThis = (CUserApp *)dwParam;

    switch (nUpdateId)
    {
    case IMAP_UPDATE_MESSAGE:
        {
            // Send a message indicating that a new message has arrived
            pThis->m_pMainWnd->PostMessage(WM_APP_NEWMESSAGE, nMessageId, 0);
        }
        break;

    case IMAP_UPDATE_EXPUNGE:
        {
            // Send a message indicating that a message has been expunged
            pThis->m_pMainWnd->PostMessage(WM_APP_EXPUNGED, nMessageId, 0);
        }
        break;
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

CImapClient::IsBlocking Method

```
BOOL IsBlocking();
```

The **IsBlocking** method is used to determine if the client is currently performing a blocking operation.

Parameters

None.

Return Value

If the client is performing a blocking operation, the method returns a non-zero value. If the client is not performing a blocking operation, or the client handle is invalid, the method returns zero.

Remarks

Because a blocking operation can allow the application to be re-entered (for example, by pressing a button while the operation is being performed), it is possible that another blocking method may be called while it is in progress. Since only one thread of execution may perform a blocking operation at any one time, an error would occur. The **IsBlocking** method can be used to determine if the client is already blocked, and if so, take some other action (such as warning the user that they must wait for the operation to complete).

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

Cancel, GetStatus, IsConnected, IsInitialized, IsReadable, IsWritable, Read, Write

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CImapClient::IsConnected Method

```
BOOL IsConnected();
```

The **IsConnected** method is used to determine if the client is currently connected to a server.

Parameters

None.

Return Value

If the client is connected to a server, the method returns a non-zero value. If the client is not connected, or the client handle is invalid, the method returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

See Also

GetStatus, IsBlocking, IsInitialized, IsReadable, IsWritable

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CImapClient::IsInitialized Method

```
BOOL IsInitialized();
```

The **IsInitialized** method returns whether or not the class object has been successfully initialized.

Return Value

This method returns a non-zero value if the class object has been successfully initialized. A return value of zero indicates that the runtime license key could not be validated or the networking library could not be loaded by the current process.

Remarks

When an instance of the class is created, the class constructor will attempt to initialize the component with the runtime license key that was created when SocketTools was installed. If the constructor is unable to validate the license key or load the networking libraries, this initialization will fail.

If SocketTools was installed with an evaluation license, the application cannot be redistributed to another system. The class object will fail to initialize if the application is executed on another system, or if the evaluation period has expired. To redistribute your application, you must purchase a development license which will include the runtime key that is needed to redistribute your software to other systems. Refer to the Developer's Guide for more information.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

CImapClient::IsReadable Method

```
BOOL IsReadable(
   INT nTimeout,
   LPDWORD lpdwAvail
);
```

The **IsReadable** method is used to determine if data is available to be read from the server.

Parameters

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

lpdwAvail

A pointer to an unsigned integer which will contain the number of bytes available to read. This parameter may be NULL if this information is not required.

Return Value

If the client can read data from the server within the specified timeout period, the method returns a non-zero value. If the client cannot read any data, the method returns zero.

Remarks

On some platforms, this value will not exceed the size of the receive buffer (typically 64K bytes). Because of differences between TCP/IP stack implementations, it is not recommended that your application exclusively depend on this value to determine the exact number of bytes available. Instead, it should be used as a general indicator that there is data available to be read.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

See Also

CImapClient::IsWritable Method

```
BOOL IsWritable(
   INT nTimeout
);
```

The **IsWritable** method is used to determine if data can be written to the server.

Parameters

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

Return Value

If the client can write data to the server within the specified timeout period, the method returns a non-zero value. If the client cannot write any data, the method returns zero.

Remarks

Although this method can be used to determine if some amount of data can be sent to the remote process it does not indicate the amount of data that can be written without blocking the client. In most cases, it is recommended that large amounts of data be broken into smaller logical blocks, typically some multiple of 512 bytes in length.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

See Also

CImapClient::Login Method

```
INT Login(
   UINT nAuthType,
   LPCTSTR lpszUserName,
   LPCTSTR lpszPassword
);

INT Login(
   LPCTSTR lpszUserName,
   LPCTSTR lpszPassword
);
```

The **Login** method authenticates the specified user in on the server. This method must be called after the connection has been established, and before attempting to retrieve messages or perform any other method on the server.

Parameters

nAuthType

Identifies the type of authentication that should be used when the client logs in to the mail server. The following authentication methods are supported:

Value	Description
IMAP_AUTH_LOGIN	Standard cleartext username and password is sent to the server. This authentication method is supported by all servers. Note that some servers may only support LOGIN authentication if a secure connection has been established.
IMAP_AUTH_PLAIN	Login using the PLAIN authentication mechanism as defined in RFC 4959. This authentication method is supported by most servers, although some may require that client establish a secure connection.
IMAP_AUTH_XOAUTH2	This authentication type will use the XOAUTH2 method to authenticate the client session. This authentication method does not require the user password, instead the ***lpszPassword*** parameter must specify the OAuth 2.0 bearer token issued by the service provider. The application must provide a valid access token which has not expired, or this method will fail.
IMAP_AUTH_BEARER	This authentication type will use the OAUTHBEARER method to authenticate the client session as defined in RFC 7628. This authentication method does not require the user password, instead the ***lpszPassword*** parameter must specify the OAuth 2.0 bearer token issued by the service provider. The application must provide a valid access token which has not expired, or this method will fail.
IMAP_AUTH_ANONYMOUS	Login using the anonymous Simple Authentication and Security Layer (SASL) mechanism as defined in RFC 4505. If this authentication method is specified, the ***lpszUserName*** parameter should specify a name or email address

	acceptable to the mail server. The *lpszPassword* parameter is ignored and may be NULL.

lpszUserName

A null-terminated string which specifies the user name to be used to authenticate the current client session.

lpszPassword

A null-terminated string which specifies the password to be used when authenticating the current client session. If you are using the IMAP_AUTH_XOAUTH2 or IMAP_AUTH_BEARER authentication methods, this parameter is not a password, instead it specifies the bearer token provided by the mail service.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

In some cases, the user may be pre-authenticated by the server. In this case, the method will fail with the last error set to ST_ERROR_ALREADY_AUTHENTICATED. If a particular authentication method is not supported by the server, the last error will be set to ST_ERROR_INVALID_AUTHENTICATION_TYPE. For compatibility with the greatest number of servers, it is recommended that you use IMAP_AUTH_LOGIN as the authentication method.

You should only use an OAuth 2.0 authentication method if you understand the process of how to request the access token. Obtaining an access token requires registering your application with the mail service provider (e.g.: Microsoft or Google), getting a unique client ID associated with your application and then requesting the access token using the appropriate scope for the service. Obtaining the initial token will typically involve interactive confirmation on the part of the user, requiring they grant permission to your application to access their mail account.

The IMAP_AUTH_XOAUTH2 and IMAP_AUTH_BEARER authentication methods are similar, but they are not interchangeable. Both use an OAuth 2.0 bearer token to authenticate the client session, but they differ in how the token is presented to the server. It is currently preferable to use the XOAUTH2 method because it is more widely available and some service providers do not yet support the OAUTHBEARER method.

Your application should not store an OAuth 2.0 bearer token for later use. They have a relatively short lifespan, typically about an hour, and are designed to be used with that session. You should specify offline access as part of the OAuth 2.0 scope if necessary and store the refresh token provided by the service. The refresh token has a much longer validity period and can be used to obtain a new bearer token when needed.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

Connect, Disconnect

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CImapClient::OpenMessage Method

```
INT OpenMessage(
   UINT nMessageId,
   UINT nMessagePart,
   DWORD dwOffset,
   LPDWORD lpdwLength,
   DWORD dwOptions
);

INT OpenMessage(
   UINT nMessageId,
   DWORD dwOptions
);
```

The **OpenMessage** method opens a message or a specific part of a multipart message in the current mailbox. The message data may also be limited a specific byte offset and length, which can be useful for previewing the contents.

Parameters

nMessageId

Number of message to retrieve. This value must be greater than zero. The first message in the mailbox is message number one.

nMessagePart

The message part that will be retrieved. A value of zero specifies that the complete message should be returned. If the message is a multipart MIME message, message parts start with a value of one.

dwOffset

The byte offset into the message. This parameter can be used in conjunction with the ***lpdwLength*** parameter to return a specific part of a message. A value of zero specifies the beginning of the message.

lpdwLength

A pointer to an unsigned integer value which should be initialized to the maximum number of bytes to be read, and will contain the size of the message when the method returns. To specify the entire message, from the offset specified by the ***dwOffset*** parameter to the end of the message, initialize the ***lpdwLength*** parameter to a value of -1. This parameter may be NULL if the message size is not needed.

dwOptions

The low order word of this parameter specifies how the message data will be returned. It may be one of the following values:

Value	Description
IMAP_SECTION_DEFAULT	All headers and the complete body of the specified message or message part are to be retrieved. The client application is responsible for parsing the header block. If the message is a MIME multipart message and the complete message is returned, the application is responsible for parsing the individual message parts if necessary.

IMAP_SECTION_HEADER	All headers for the specified message or message part are to be retrieved. The client application is responsible for parsing the header block.
IMAP_SECTION_MIMEHEADER	The MIME headers for the specified message or message are to be retrieved. Only those header fields which are used in MIME messages, such as Content-Type will be returned to the client. This is typically useful when processing the header for a multipart message which contains file attachments. The client application is responsible for parsing the header block.
IMAP_SECTION_BODY	The body of the specified message or message part is to be retrieved. For a MIME formatted message, this may include data that is uuencoded or base64 encoded. The application is responsible for decoding this data.
IMAP_SECTION_PREVIEW	The message header or body is being previewed and should not be marked as read by the server. This prevents the message from having the IMAP_FLAG_SEEN flag from being automatically set when the message data is retrieved.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **OpenMessageEx** method uses the FETCH command to access the specified message on the server. The client can then use the **Read** method to read the contents of the message.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CloseMessage, GetMessage, GetMessageHeaders, OpenMessage, Read, StoreMessage

CImapClient::Read Method

```
INT Read(
   LPBYTE lpBuffer,
   INT cbBuffer
);

INT Read(
   CString& strBuffer,
   INT cbBuffer
);
```

The **Read** method reads the specified number of bytes from the client socket and copies them into the buffer. The data may be of any type, and is not terminated with a null character.

Parameters

lpBuffer

Pointer to the buffer in which the data will be copied. An alternate form of this method allows a **CString** variable to be passed and data read from the socket will be returned in that string.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

Return Value

If the method succeeds, the return value is the number of bytes actually read. A return value of zero indicates that the server has closed the connection and there is no more data available to be read. If the method fails, the return value is IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

When **Read** is called and the client is in non-blocking mode, it is possible that the method will fail because there is no available data to read at that time. This should not be considered a fatal error. Instead, the application should simply wait to receive the next asynchronous notification that data is available.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

See Also

EnableEvents, IsBlocking, IsReadable, IsWritable, RegisterEvent, Write

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CImapClient::RegisterEvent Method

```
INT RegisterEvent(
   UINT nEventId,
   IMAPEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

The **RegisterEvent** method registers an event handler for the specified event.

Parameters

nEventId

An unsigned integer which specifies which event should be registered with the specified callback function. One of the following values may be used:

Value	Description
IMAP_EVENT_CONNECT	The connection to the server has completed.
IMAP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
IMAP_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
IMAP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
IMAP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
IMAP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
IMAP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.
IMAP_EVENT_PROGRESS	The client is in the process of sending or receiving a file on the data channel. This event is called periodically during a transfer so that the client can update any user interface components such as a status control or progress bar.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **ImapEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **RegisterEvent** method associates a callback function with a specific event. The event handler is an **ImapEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

This method is typically used to register an event handler that is invoked while a message is being retrieved. The IMAP_EVENT_PROGRESS event will only be generated periodically during the transfer to ensure the application is not flooded with event notifications. It is guaranteed that at least one IMAP_EVENT_PROGRESS notification will occur at the beginning of the transfer, and one at the end of the transfer when it has completed.

The callback function specified by the *lpEventProc* parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

The *dwParam* parameter is commonly used to identify the class instance which is associated with the event that has occurred. Applications will cast the **this** pointer to a DWORD_PTR value when calling this function, and then the event handler will cast it back to a pointer to the class instance. This gives the handler access to the class member variables and methods.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

CImapClient::RenameMailbox Method

```
INT RenameMailbox(
   LPCTSTR lpszOldMailbox,
   LPCTSTR lpszNewMailbox
);
```

The **RenameMailbox** method renames an existing mailbox.

Parameters

lpszOldMailbox

A null-terminated string which specifies the mailbox to be renamed.

lpszNewMailbox

A null-terminated string which specifies the new mailbox name.

Return Value

If the method succeeds, it returns zero. If an error occurs, the method returns IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **RenameMailbox** method renames an existing mailbox on the server. The new mailbox name cannot exist on the server, or the method will fail.

If the existing mailbox name contains inferior hierarchical names (mailboxes under the specified mailbox) then those mailboxes will also be renamed. For example, if the mailbox "Mail/Pictures" contains two mailboxes, "Personal" and "Work" and it is renamed to "Mail/Images" then the two mailboxes under it would be automatically renamed to "Mail/Images/Personal" and "Mail/Images/Work".

If the mailbox being renamed is the currently selected mailbox, the current mailbox will be unselected and any messages marked for deletion will be expunged. The new mailbox name will then automatically be re-selected. To prevent deleted messages from being removed from the mailbox prior to being renamed, use the **UnselectMailbox** method to unselect the current mailbox before calling **RenameMailbox**. Note that if the rename operation fails, the client may be left in an unselected state.

It is permitted to rename the special mailbox INBOX. In this case, the messages will be moved from the INBOX mailbox to the new mailbox. If the INBOX mailbox is currently selected, the new mailbox will not automatically be selected. INBOX will remain the selected mailbox.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

CImapClient::ReselectMailbox Method

```
BOOL ReselectMailbox(
   LPIMAPMAILBOX lpMailboxInfo
);
```

The **ReselectMailbox** method reselects the current mailbox and returns updated information about the status of the mailbox.

Parameters

lpMailboxInfo

A pointer to an IMAPMAILBOX structure which contains updated information about the mailbox when the method returns. This parameter may be NULL if the caller does not require any information about the mailbox.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **ReselectMailbox** method forces the current mailbox to be reselected and returns updated information about the status of the mailbox. Deleted messages are not expunged from the mailbox and remain marked for deletion.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

CImapClient::SearchMailbox Method

```
LONG SearchMailbox(
   LPCTSTR lpszCriteria,
   LPCTSTR lpszCharacterSet,
   UINT *lpnMessageIds,
   LONG nMaxMessages
);

LONG SearchMailbox(
   LPCTSTR lpszCriteria,
   UINT *lpnMessageIds,
   LONG nMaxMessages
);
```

The **SearchMailbox** method searches the current mailbox for messages that match the specified criteria, returning matching message identifiers.

Parameters

lpszCriteria

A null-terminated string which specifies the search criteria.

lpszCharacterSet

A null-terminated string which specifies the character set to use when searching the mailbox. If this parameter is NULL or an empty string, the default US-ASCII character set will be used.

dwReserved

A reserved parameter which should be set to the value 0.

lpnMessageIds

A pointer to an array of unsigned integers that will contain the message identifiers of those messages which match the search criteria in the current mailbox. This parameter may be NULL, in which case the method will return the number of matching messages but will not return their identifiers.

nMaxMessages

The maximum number of message identifiers that may be stored in the ***lpnMessageIds*** array. If the ***lpnMessageIds*** parameter is NULL, this value should be zero.

Return Value

If the method succeeds, the return value is the number of messages that meet the search criteria in the current mailbox. If the method fails, the return value is IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **SearchMailbox** method is used to search a mailbox for messages which match a given criteria and return a list of the matching message identifiers. The search criteria is composed of one or more search keywords and and optional value to match against. String searches are not case sensitive and partial matches in the message are returned.

The following search keywords are recognized:

Keyword	Description
ANSWERED	Match those messages which have the IMAP_FLAG_ANSWERED flag set.

BCC *address*	Match those messages which contain the specified address in the BCC header field.
BEFORE *date*	Match those messages which were added to the mailbox prior to the specified date.
BODY *string*	Match those messages where the body contains the specified string.
CC *address*	Match those messages which contain the specified address in the CC header field.
DELETED	Match those messages which have the IMAP_FLAG_DELETED flag set.
DRAFT	Match those messages which have the IMAP_FLAG_DRAFT flag set.
FLAGGED	Match those messages which have the IMAP_FLAG_URGENT flag set.
FROM *address*	Match those messages which contain the specified address in the FROM header field.
HEADER *field string*	Match those messages which contain the string in the specified header field. If no string is specified, then all messages which contain the header will be matched.
LARGER *size*	Match those messages which are larger than the specified size in bytes.
NEW	Match those messages which have the IMAP_FLAG_RECENT flag set, but not the IMAP_FLAG_SEEN flag.
OLD	Match those messages which do not have the IMAP_FLAG_RECENT flag set.
ON *date*	Match those messages which were added on the specified date.
RECENT	Match those messages which have the IMAP_FLAG_RECENT flag set.
SEEN	Match those messages which have the IMAP_FLAG_SEEN flag set.
SENTBEFORE *date*	Match those messages whose Date header value is earlier than the specified date.
SENTON *date*	Match those messages whose Date header value is the same as the specified date.
SENTSINCE *date*	Match those messages whose Date header value is later than the specified date.
SINCE *date*	Match those messages added to the mailbox after the specified date.
SMALLER *size*	Match those messages which are smaller than the specified size in bytes.
SUBJECT *string*	Match those messages whose Subject header contains the specified string.
TEXT *string*	Match those messages whose headers or body contains the specified string.
TO *address*	Match those messages which contain the specified address in the TO header field.
UID *sequence*	Match those messages with unique identifiers in the sequence set.
UNANSWERED	Match those messages which do not have the IMAP_FLAG_ANSWERED

	flag set.
UNDELETED	Match those messages which do not have the IMAP_FLAG_DELETED flag set.
UNDRAFT	Match those messages which do not have the IMAP_FLAG_DRAFT flag set.
UNFLAGGED	Match those messages which do not have the IMAP_FLAG_URGENT flag set.
UNSEEN	Match those messages which do not have the IMAP_FLAG_SEEN flag set.

In addition to the listed keywords, the keyword NOT may prefix a keyword to return those messages which do not match the search criteria. For example, "NOT TO user@domain.com" would return those messages which were not addressed to user@domain.com.

If multiple search keywords are specified, the result is the intersection of all those messages which meet the search criteria. For example, a search criteria of "DELETED SINCE 1-Jan-2003" would return all those messages which are marked for deletion and were added to the mailbox after 1 January 2003.

Those search keywords which expect dates must be specified in format ***dd-mmm-yyyy*** where the month is the three letter abbreviation for the month name. Note that the internal date the message was added to the mailbox is not the same as the value of the Date header field in the message.

The UID keyword expects a one or more unique message identifiers. These values may provided as comma separated list, or a range delimited by a colon. For example, "UID 23000:24000" would return all those messages who have UIDs ranging from 23000 through to 24000.

The message identifiers returned by this method are only valid until the mailbox is expunged or another mailbox is selected.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

CImapClient::SelectMailbox Method

```
INT SelectMailbox(
   LPCTSTR lpszMailbox,
   LPIMAPMAILBOX lpMailboxInfo
);
```

The **SelectMailbox** method selects the specified mailbox for read-write access.

Parameters

lpszMailbox

A null-terminated string which specifies the new mailbox to be selected.

lpMailboxInfo

A pointer to an IMAPMAILBOX structure which contains information about the mailbox when the method returns. This parameter may be NULL if the caller does not require any information about the mailbox.

Return Value

If the method succeeds, it returns zero. If an error occurs, the method returns IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **SelectMailbox** method is used to select a mailbox in read-write mode. If the client has a different mailbox currently selected, that mailbox will be closed and any messages marked for deletion will be expunged. To prevent deleted messages from being removed from the previous mailbox, use the **UnselectMailbox** method prior to selecting the new mailbox.

If you need to select a mailbox which contains Unicode characters or symbols, it is recommended you use the Unicode character set when compiling your application. The mailbox name will automatically be converted to modified UTF-7 encoding as defined by the IMAP4 standard. If you do not use Unicode, this method will only accept mailbox names using modified UTF-7 encoding or UTF-8 encoding.

If an application wishes to update the information returned in the IMAPMAILBOX structure for the current mailbox, simply call **SelectMailbox** again with the same mailbox name. Note that this will not cause any messages marked for deletion to be expunged.

The special case-insensitive mailbox name INBOX is used for new messages. Other mailbox names may or may not be case-sensitive depending on the IMAP server's operating system and implementation.

To access a mailbox in read-only mode, use the **ExamineMailbox** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

CImapClient::SetLastError Method

```
VOID SetLastError(
   DWORD dwErrorCode
);
```

The **SetLastError** method sets the last error code for the current thread. This method is typically used to clear the last error by specifying a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or IMAP_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

Applications can retrieve the value saved by this method by using the **GetLastError** method. The use of **GetLastError** is optional; an application can call the method to determine the specific reason for a method failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

CImapClient::SetMessageFlags Method

```
INT SetMessageFlags(
   UINT nMessageId,
   UINT nMode
   DWORD dwMessageFlags
);
```

The **SetMessageFlags** method returns the message flags for the specified message.

Parameters

nMessageId

Number of message to obtain the message flags for. This value must be greater than zero. The first message in the mailbox is message number one.

nMode

An unsigned integer value which specifies one of the following modes which determines how the message flags are set:

Value	Description
IMAP_FLAGS_REPLACE	All message flags are replaced with the flags specified by the ***dwMessageFlags*** parameter.
IMAP_FLAGS_ADD	The message flags specified by the ***dwMessageFlags*** parameter will be set for the message. Message flags that have been previously set will remain unmodified.
IMAP_FLAGS_REMOVE	The message flags specified by the ***dwMessageFlags*** parameter will be removed from the message. Message flags that are not specified will remain unmodified.

dwMessageFlags

An unsigned integer value which specifies one or more message flags. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
IMAP_FLAG_ANSWERED	The message has been answered.
IMAP_FLAG_DELETED	The message has been marked for deletion.
IMAP_FLAG_DRAFT	The message has not been completed and is marked as a draft copy.
IMAP_FLAG_URGENT	The message has been flagged for urgent or special attention.
IMAP_FLAG_RECENT	The message has been added to the mailbox recently.
IMAP_FLAG_SEEN	The message has been read.

Return Value

If the method succeeds, it returns IMAP_RESULT_OK. If an error occurs, the method returns IMAP_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

See Also

CImapClient::SetTimeout Method

```
INT SetTimeout(
   UINT nTimeout
);
```

The **SetTimeout** method sets the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the method will fail and return to the caller.

Parameters

nTimeout

The number of seconds to wait for a blocking operation to complete.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The timeout value is only used with blocking client connections.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

See Also

CImapClient::ShowError Method

```
INT ShowError(
   LPCTSTR lpszAppTitle,
   UINT uType,
   DWORD dwErrorCode
);
```

The **ShowError** method displays a message box which describes the specified error.

Parameters

lpszAppTitle

A null-terminated string which specifies the title of the message box that is displayed. If this argument is NULL or omitted, then the default title of "Error" will be displayed.

uType

An unsigned integer which specifies the type of message box that will be displayed. This is the same value that is used by the **MessageBox** method in the Windows API. If a value of zero is specified, then a message box with a single OK button will be displayed. Refer to that method for a complete list of options.

dwErrorCode

Specifies the error code that will be used when displaying the message box. If this argument is zero, then the last error that occurred in the current thread will be displayed.

Return Value

If the method is successful, the return value will be the return value from the **MessageBox** function. If the method fails, it will return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetErrorString, GetLastError, SetLastError

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CImapClient::StoreMessage Method

```
INT StoreMessage(
   UINT nMessageId,
   LPCTSTR lpszFileName
);
```

The **StoreMessage** method retrieves a message from the current mailbox and stores it in a local file or the system clipboard.

Parameters

nMessageId

Number of the message to retrieve. This value must be greater than zero. The first message in the mailbox is message number one.

lpszFileName

Pointer to a string which specifies the file that the message will be stored in. If an empty string or NULL pointer is passed as an argument, the message is copied to the system clipboard.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **StoreMessage** method provides a method of retrieving and storing a message on the local system. The contents of the message is stored as a text file, using the specified file name. This method always causes the caller to block until the entire message has been retrieved, even if the client has been put in asynchronous mode.

If event handling is enabled, the IMAP_EVENT_PROGRESS event will fire periodically during the transfer of the message to the local system. An application can determine how much of the message has been retrieved by calling the **GetTransferStatus** method.

To retrieve the message into a global memory buffer so that it can be passed to the MIME or SMTP libraries, use the **GetMessage** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetMessage, GetMessageHeaders, GetTransferStatus

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CImapClient::SubscribeMailbox Method

```
INT SubscribeMailbox(
   LPCTSTR lpszMailbox
);
```

The **SubscribeMailbox** method subscribes the user to the specified mailbox.

Parameters

lpszMailbox

A null-terminated string which specifies the mailbox to subscribe to.

Return Value

If the method succeeds, it returns zero. If an error occurs, the method returns IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **SubscribeMailbox** method adds the specified mailbox to the current user's list of active or subscribed mailboxes. The user will remain subscribed to the mailbox across multiple sessions, until the **UnsubscribeMailbox** method is called to remove the mailbox from the subscription list.

To list those mailboxes which the user has subscribed to, use the **GetFirstMailbox** method and specify the IMAP_LIST_SUBSCRIBED option.

Note that if a user subscribes to a mailbox and that mailbox is later renamed or deleted, the mailbox will not be automatically removed from the user's subscription list. An application must not assume that because a mailbox name is included in the list of subscribed mailboxes, it exists and can be selected. To check if the mailbox exists, use the **GetMailboxStatus** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

CImapClient::UndeleteMessage Method

```
INT UndeleteMessage(
   UINT nMessageId
);
```

The **UndeleteMessage** method removes the deletion flag for the specified message.

Parameters

nMessage

Number of message to undelete from the server. This value must be greater than zero. The first message in the mailbox is message number one.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is IMAP_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

See Also

CImapClient::UnselectMailbox Method

```
INT UnselectMailbox(
   BOOL bExpunge
);
```

The **UnselectMailbox** method unselects the current mailbox.

Parameters

bExpunge

A boolean flag which determines if deleted messages will be expunged from the mailbox. A non-zero value specifies that messages that have been marked for deletion will be removed from the mailbox. A zero value specifies that no messages will be removed from the mailbox.

Return Value

If the method succeeds, it returns zero. If an error occurs, the method returns IMAP_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

See Also

DeleteMailbox, ExamineMailbox, GetFirstMailbox, GetMailboxStatus, GetNextMailbox, RenameMailbox, ReselectMailbox, SelectMailbox

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CImapClient::UnsubscribeMailbox Method

```
INT UnsubscribeMailbox(
   LPCTSTR lpszMailbox
);
```

The **UnsubscribeMailbox** method unsubscribes the user from the specified mailbox.

Parameters

lpszMailbox

A null-terminated string which specifies the mailbox to unsubscribe from.

Return Value

If the method succeeds, it returns zero. If an error occurs, the method returns IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **UnsubscribeMailbox** method removes the specified mailbox from the current user's list of active or subscribed mailboxes.

To list those mailboxes which the user has subscribed to, use the **GetFirstMailbox** method and specify the IMAP_LIST_SUBSCRIBED option.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CImapClient::Write Method

```
INT Write(
   LPBYTE lpBuffer,
   INT cbBuffer
);

INT Write(
   LPCTSTR lpszBuffer
   INT cbBuffer
);
```

The **Write** method sends the specified number of bytes to the server.

Parameters

lpBuffer

The pointer to the buffer which contains the data that is to be sent to the server. In an alternate form of the method, the pointer is to a string.

cbBuffer

The number of bytes to send from the specified buffer. This value must be greater than zero, unless a pointer to a string is passed as the buffer argument. In that case, if the value is -1, all of the characters in the string, up to but not including the terminating null character, will be sent to the server.

Return Value

If the method succeeds, the return value is the number of bytes actually written. If the method fails, the return value is IMAP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The return value may be less than the number of bytes specified by the ***cbBuffer*** parameter. In this case, the data has been partially written and it is the responsibility of the client application to send the remaining data at some later point. For non-blocking clients, the client must wait for the next asynchronous notification message before it resumes sending data.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

- IMAPMESSAGE
- IMAPTRANSFERSTATUS
- SECURITYCREDENTIALS
- SECURITYINFO
- SYSTEMTIME

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

IMAPMAILBOX

This structure contains information about a selected mailbox.

```
typedef struct _IMAPMAILBOX
{
    UINT    nMessages;
    UINT    nRecentMessages;
    UINT    nUnseenMessageId;
    DWORD   dwMailboxUID;
    DWORD   dwNextMessageUID;
    DWORD   dwFlags;
    DWORD   dwPermanentFlags;
    DWORD   dwAccessMode;
    DWORD   dwReserved1;
    DWORD   dwReserved2;
} IMAPMAILBOX, *LPIMAPMAILBOX;
```

Members

nMessages

A value specifies the total number of messages in the mailbox.

nRecentMessages

A value which specifies the number of new messages that have recently arrived in the mailbox.

nUnseenMessageId

A value which specifies the message ID of the first unseen message in the mailbox.

dwMailboxUID

A value which specifies a unique identifier for this mailbox which corresponds to the UIDVALIDITY value returned by the IMAP server. The actual value is determined by the server and should be considered opaque. The protocol specification requires that a mailbox's UID must not change unless the mailbox contents are modified or existing messages in the mailbox have been assigned new UIDs.

dwNextMessageUID

A value which specifies the predicted unique identifier that will be assigned to a new message in the mailbox. This corresponds to the UIDNEXT value returned by the IMAP server. The protocol specification requires that as long as the mailbox UID is unchanged, messages that are added to the mailbox will be assigned a UID greater than or equal to the next UID value.

dwFlags

A value which specifies one or more mailbox flags. One or more of the following values may be specified:

Value	Description
IMAP_FLAG_NOINFERIORS	The mailbox does not contain any child mailboxes. In the IMAP protocol, these are referred to as inferior hierarchical mailbox names.
IMAP_FLAG_NOSELECT	The mailbox cannot be selected or examined. This flag is typically used by servers to indicate that the mailbox name refers to a directory on the server, not a mailbox file.
IMAP_FLAG_MARKED	The mailbox is marked as being of interest to a client. If this

	flag is used, it typically means that the mailbox contains messages. An application should not depend on this flag being present for any given mailbox. Some IMAP servers do not support marked or unmarked flags for mailboxes.
IMAP_FLAG_UNMARKED	The mailbox is marked as not being of interest to a client. If this flag is used, it typically means that the mailbox does not contain any messages. An application should not depend on this flag being present for any given mailbox. Some IMAP servers do not support marked or unmarked flags for mailboxes.

dwPermanentFlags

A value which specifies the message flags that a client can change permanently. If this value is zero, then no permanent flags are defined for the mailbox and the client may assume that all message flags may be set permanently. Otherwise, one or more of the following values may be specified:

Value	Description
IMAP_FLAG_ANSWERED	The message has been answered.
IMAP_FLAG_DRAFT	The message has not been completed and is marked as a draft copy.
IMAP_FLAG_URGENT	The message has been flagged for urgent or special attention.
IMAP_FLAG_SEEN	The message has been read.

dwAccessMode

A value which specifies the access mode for the mailbox. It may be one of the following values:

Value	Description
IMAP_ACCESS_READONLY	The mailbox has been selected in read-only mode. Messages may not be created in the mailbox, nor can message flags be modified.
IMAP_ACCESS_READWRITE	The mailbox has been selected in read-write mode. Messages may be modified by the client, and messages marked for deletion can be expunged.

dwReserved1

A reserved value that is undefined.

dwReserved2

A reserved value that is undefined.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

IMAPMAILBOXSTATUS

This structure contains information about a mailbox.

```
typedef struct _IMAPMAILBOXSTATUS
{
    UINT    nMessages;
    UINT    nRecentMessages;
    UINT    nUnseenMessages;
    DWORD   dwMailboxUID;
    DWORD   dwNextMessageUID;
    DWORD   dwReserved;
} IMAPMAILBOXSTATUS, *LPIMAPMAILBOXSTATUS;
```

Members

nMessages

A value specifies the total number of messages in the mailbox.

nRecentMessages

A value which specifies the number of new messages that have recently arrived in the mailbox.

nUnseenMessages

A value which specifies the number of unread messages in the mailbox.

dwMailboxUID

A value which specifies a unique identifier for this mailbox which corresponds to the UIDVALIDITY value returned by the IMAP server. The actual value is determined by the server and should be considered opaque. The protocol specification requires that a mailbox's UID must not change unless the mailbox contents are modified or existing messages in the mailbox have been assigned new UIDs.

dwNextMessageUID

A value which specifies the predicted unique identifier that will be assigned to a new message in the mailbox. This corresponds to the UIDNEXT value returned by the IMAP server. The protocol specification requires that as long as the mailbox UID is unchanged, messages that are added to the mailbox will be assigned a UID greater than or equal to the next UID value.

dwReserved

A reserved value that is undefined.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

IMAPMESSAGE

This structure contains information about a message.

```
typedef struct _IMAPMESSAGE
{
    UINT    nMessageId;
    DWORD   dwMessageUID;
    DWORD   dwSize;
    DWORD   dwFlags;
    DWORD   dwTimestamp;
    DWORD   dwReserved;
} IMAPMESSAGE, *LPIMAPMESSAGE;
```

Members

nMessageId

An sequential integer value which identifies the message. The message identifier is only valid while the mailbox is selected and no messages marked for deletion have been expunged. To maintain a persistent identifier for the message, use a combination of the mailbox UID and message UID.

dwMessageUID

An integer value which specifies a unique identifier for this message. The actual value is determined by the server and should be considered opaque. If the client application stores the message UID on the local system, it should also store the UID for the mailbox that contains the message. If the mailbox UID changes, the message UID may no longer be valid.

dwSize

Specifies the size of the message in bytes. This value may not be the same as the number of characters in the message, particularly if the message text uses Unicode or extended multibyte ANSI sequences. For a structured multipart MIME message, this includes the combined size of all message parts.

dwFlags

A value which specifies one or more message flags. One or more of the following values may be specified:

Value	Description
IMAP_FLAG_NONE	No value.
IMAP_FLAG_ANSWERED	The message has been answered.
IMAP_FLAG_DELETED	The message has been marked for deletion.
IMAP_FLAG_DRAFT	The message has not been completed and is marked as a draft copy.
IMAP_FLAG_URGENT	The message has been flagged for urgent or special attention.
IMAP_FLAG_RECENT	The message has been added to the mailbox recently.
IMAP_FLAG_SEEN	The message has been read.

dwTimestamp

An integer value which specifies the date and time that the message was added to the mailbox. The value is expressed as the number of seconds since midnight, 1 January 1970 and is the same value that is used for the standard C runtime library time methods. Note that the date and time used is

the message's internal date from the mail server, not the value of the **Date** header field in the message.

dwReserved

A reserved value that is undefined.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

IMAPTRANSFERSTATUS

This structure is used by the GetTransferStatus method to return information about a file transfer in progress.

```
typedef struct _IMAPTRANSFERSTATUS
{
   UINT    nMessageId;
   DWORD   dwBytesTotal;
   DWORD   dwBytesCopied;
   DWORD   dwBytesPerSecond;
   DWORD   dwTimeElapsed;
   DWORD   dwTimeEstimated;
} IMAPTRANSFERSTATUS, *LPIMAPTRANSFERSTATUS;
```

Members

nMessageId

The message ID of the current message that is being transferred.

dwBytesTotal

The total number of bytes that will be transferred. If the file is being copied from the server to the local host, this is the size of the remote file. If the file is being copied from the local host to the server, it is the size of the local file. If the file size cannot be determined, this value will be zero.

dwBytesCopied

The total number of bytes that have been copied.

dwBytesPerSecond

The average number of bytes that have been copied per second.

dwTimeElapsed

The number of seconds that have elapsed since the file transfer started.

dwTimeEstimated

The estimated number of seconds until the file transfer is completed. This is based on the average number of bytes transferred per second.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SECURITYCREDENTIALS

The **SECURITYCREDENTIALS** structure specifies the information needed by the library to specify additional security credentials, such as a client certificate, when establishing a secure connection.

```
typedef struct _SECURITYCREDENTIALS
{
    DWORD    dwSize;
    DWORD    dwProtocol;
    DWORD    dwOptions;
    DWORD    dwReserved;
    LPCTSTR  lpszHostName;
    LPCTSTR  lpszUserName;
    LPCTSTR  lpszPassword;
    LPCTSTR  lpszCertStore;
    LPCTSTR  lpszCertName;
    LPCTSTR  lpszKeyFile;
} SECURITYCREDENTIALS, *LPSECURITYCREDENTIALS;
```

Members

dwSize

Size of this structure. If the structure is being allocated dynamically, this member must be set to the size of the structure and all other unused structure members must be initialized to a value of zero or NULL.

dwProtocol

A bitmask of supported security protocols. The value of this structure member is constructed by using a bitwise operator with any of the following values:

Value	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_TLS	Either the TLS 1.2 or 1.3 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers which reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing

	a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Value	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

dwReserved

This structure member is reserved for future use and should always be initialized to zero.

lpszHostName

A null-terminated string which specifies the hostname that will be used when validating the server certificate. If this member is NULL, then the server certificate will be validated against the hostname used to establish the connection.

lpszUserName

A null-terminated string which identifies the owner of client certificate. Currently this member is not used by the library and should always be initialized as a NULL pointer.

lpszPassword

A null-terminated string which specifies the password needed to access the certificate. Currently this member is only used if the CREDENTIAL_STORE_FILENAME option has been specified. If there is no password associated with the certificate, then this member should be initialized as a NULL pointer.

lpszCertStore

A null-terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A null-terminated string which specifies the name of the certificate to use. The library will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the library will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the library will return an error indicating that the certificate could not be found. If the SECURITY_PROTOCOL_SSH protocol has been specified, this member should be NULL.

lpszKeyFile

This member is not used and should always be NULL. The private key cannot be specified separately and must be associated with the certificate.

Remarks

An application only needs to create this structure if the server requires the client to provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is

specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The ***dwOptions*** member should be set to CREDENTIAL_STORE_FILENAME and the ***lpszCertStore*** member should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS #12. These certificate files typically have an extension of .pfx or .p12. Note that if a password was specified when the certificate file was created, it must be provided in the ***lpszPassword*** member or the library will be unable to access the certificate.

Note that the ***lpszUserName*** and ***lpszPassword*** members are values which are used to access the certificate store or private key file. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SECURITYINFO

The **SECURITYINFO** structure contains security related information about the connection, including the protocol, cipher suite and certificate.

```
typedef struct _SECURITYINFO
{
   DWORD        dwSize;
   DWORD        dwProtocol;
   DWORD        dwCipher;
   DWORD        dwCipherStrength;
   DWORD        dwHash;
   DWORD        dwHashStrength;
   DWORD        dwKeyExchange;
   DWORD        dwCertStatus;
   SYSTEMTIME   stCertIssued;
   SYSTEMTIME   stCertExpires;
   LPCTSTR      lpszCertIssuer;
   LPCTSTR      lpszCertSubject;
   LPCTSTR      lpszFingerprint;
} SECURITYINFO, *LPSECURITYINFO;
```

Members

dwSize

Specifies the size of the data structure. This member must always be initialized to the size of the structure in bytes prior to passing the address of this structure to the function. If this this member is not initialized, an error will be returned indicating that an invalid parameter has been passed to the function.

dwProtocol

A numeric value which specifies the security protocol selected when establishing the connection.

Value	Description
SECURITY_PROTOCOL_NONE	The connection is not secure. This value indicates a standard connection was established and all other structure members will have a value of zero.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol was selected when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol was selected when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.

SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol was selected when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol was selected when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwCipher

A numeric value which specifies the cipher that was selected when establishing the secure connection.

Value	Description
SECURITY_CIPHER_AES	The Advanced Encryption Standard cipher is a fixed block size cipher which use a key size of 128, 192 or 256 bits.
SECURITY_CIPHER_DES	The Data Encryption Standard block cipher was selected. This is a fixed key length cipher, using 56-bit keys.
SECURITY_CIPHER_DES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively providing a 168-bit length key.
SECURITY_CIPHER_DESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.
SECURITY_CIPHER_RC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40 and 128 bits, in 8-bit increments.
SECURITY_CIPHER_RC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.

dwCipherStrength

A numeric value which specifies the strength (the length of the cipher key in bits) of the cipher that was selected. Typically this value will be 128 or 256. 40-bit and 56-bit key lengths are considered weak encryption, and subject to brute force attacks. 128-bit and 256-bit key lengths are considered to be secure, and are the recommended key length for secure communications.

dwHash

A numeric value which specifies the hash algorithm which was selected.

Value	Description
SECURITY_HASH_MD5	The MD5 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA1	The SHA-1 algorithm was selected. Its use has been deprecated and is no longer considered to be

	cryptographically secure.
SECURITY_HASH_SHA256	The SHA-256 algorithm was selected.
SECURITY_HASH_SHA384	The SHA-384 algorithm was selected.
SECURITY_HASH_SHA512	The SHA-512 algorithm was selected.

dwHashStrength

A numeric value which specifies the strength (the length in bits) of the message digest that was selected.

dwKeyExchange

A numeric value which specifies the key exchange algorithm which was selected.

Value	Description
SECURITY_KEYEX_RSA	The RSA public key algorithm was selected.
SECURITY_KEYEX_KEA	The Key Exchange Algorithm (KEA) was selected. This is an improved version of the Diffie-Hellman public key algorithm.
SECURITY_KEYEX_DH	The Diffie-Hellman key exchange algorithm was selected.
SECURITY_KEYEX_ECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography.

dwCertStatus

A numeric value which specifies the status of the certificate returned by the secure server.

Value	Description
SECURITY_CERTIFICATE_VALID	The certificate is valid.
SECURITY_CERTIFICATE_NOMATCH	The certificate is valid, but the domain name does not match the common name in the certificate.
SECURITY_CERTIFICATE_EXPIRED	The certificate is valid, but has expired.
SECURITY_CERTIFICATE_REVOKED	The certificate has been revoked and is no longer valid.
SECURITY_CERTIFICATE_UNTRUSTED	The certificate or certificate authority is not trusted on the local system.
SECURITY_CERTIFICATE_INVALID	The certificate is invalid. This typically indicates that the internal structure of the certificate has been damaged.

stCertIssued

A structure which contains the date and time that the certificate was issued by the certificate authority. If the issue date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values.

stCertExpires

A structure which contains the date and time that the certificate expires. If the expiration date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values.

lpszCertIssuer

A null-terminated string which contains information about the organization that issued the certificate. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate issuer could not be determined, this member may be NULL.

lpszCertSubject

A null-terminated string which contains information about the organization that the certificate was issued to. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate subject could not be determined, this member may be NULL.

lpszFingerprint

A null-terminated string which contains a sequence of hexadecimal values that uniquely identify the server. This member may be NULL.

Remarks

The size of this structure is typically determined using the **sizeof** operator in C/C++ and most other languages have a similar method for obtaining the size of a data structure or user-defined type. It is important to note the size of this structure will be different on 32-bit and 64-bit platforms due to the difference in the length of the structure members which are pointers.

When evaluating structure members which are string pointers, such as ***lpszCertIssuer*** and ***lpszCertSubject***, you should always check to ensure their values are not NULL (zero) before attempting to dereference them. If those values are undefined, it is not guaranteed they will point to zero-length strings.

There are additional protocols and ciphers defined which are not listed above because they are considered insecure and are no longer supported. It is important to note that most servers will reject attempts to use unsupported protocols such as SSL 3.0 and will either abort the connection or issue an error message and then immediately disconnect.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SYSTEMTIME

The **SYSTEMTIME** structure represents a date and time using individual members for the month, day, year, weekday, hour, minute, second, and millisecond.

```
typedef struct _SYSTEMTIME
{
    WORD wYear;
    WORD wMonth;
    WORD wDayOfWeek;
    WORD wDay;
    WORD wHour;
    WORD wMinute;
    WORD wSecond;
    WORD wMilliseconds;
} SYSTEMTIME, *LPSYSTEMTIME;
```

Members

wYear

Specifies the current year. The year value must be greater than 1601.

wMonth

Specifies the current month. January is 1, February is 2 and so on.

wDayOfWeek

Specifies the current day of the week. Sunday is 0, Monday is 1 and so on.

wDay

Specifies the current day of the month

wHour

Specifies the current hour.

wMinute

Specifies the current minute

wSecond

Specifies the current second.

wMilliseconds

Specifies the current millisecond.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Internet Server Class Library

A general purpose TCP/IP networking library for developing server applications.

Reference

- Data Members
- Class Methods
- Event Handlers
- Data Structures
- Error Codes

Library Information

Class Name	CInternetServer
File Name	CSWSKV12.DLL
Version	12.0.3024.1286
LibID	99EEE601-E935-4266-B046-771A823DB47D
Import Library	CSWSKV12.LIB
Dependencies	None
Standards	RFC 768, RFC 791, RFC 793

Overview

The Internet Server class library provides a simplified interface for creating event-driven, multithreaded server applications using the TCP/IP protocol. Each instance of the Internet Server class represents a server, and each active client connection is managed internally and referenced by a handle which uniquely identifies the client session. The class library supports secure connections using the standard TLS protocol and can be used to create secure, custom server programs.

This class is designed to be used as a base class from which your own server class is derived. To exchange data with the clients that connect to the server, you should override the default events such as **OnConnect** and **OnRead**. Most interaction with the clients occur within these event handlers. Because the client sessions are managed in worker threads that are separate from the main UI thread of your application, you may perform a blocking operation in response to an event without affecting the other clients that are connected to the server.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). You should install all updates for your development tools and have the current Windows SDK installed. The minimum supported version of Visual Studio is Visual Studio 2010 with Service Pack 1 (SP1) installed. The SocketTools header files are designed to be compatible with all modern C/C++ compilers and we also provide function definitions for several additional languages such as Object Pascal and Visual Basic.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are deploying applications to Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. If you are deploying applications to Windows 8, you must

have the 8.1 update installed. If you are targeting the Windows on ARM platform, the minimum required version is Windows 10 build 1709.

SocketTools includes support for both 64-bit and 32-bit Windows platforms. All current versions of Windows are 64-bit, and we include 32-bit x86 libraries to maintain compatibility with legacy development tools. SocketTools also provides native ARM64 libraries for systems running Windows on ARM. Note that 32-bit applications on ARM use x86 emulation, and Microsoft no longer supports native 32-bit ARM (ARM32) applications. Embarcadero's C++Builder and Delphi compilers (as of version 12.3) do not support building native ARM64 applications for Windows. For developing applications targeting the Windows on ARM platform, we recommend using Visual Studio 2019 or later.

The import libraries included with SocketTools are provided in several different formats. The most commonly used format is COFF, which is available for x64, x86 and native ARM64 platforms. For compatibility with older Borland (Embarcadero) compilers, we also provide OMF libraries for x86 platforms and ELF libraries for x64 platforms. If you are using Visual Studio, you will want to use the standard COFF import libraries. Note that some languages may not require import libraries and will link to the exported functions in the DLL based on the function declaration itself.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

CInternetServer Public Data Members

Member Variables	Description
m_nBacklog	The size of the backlog connection queue for the server
m_nMaxClients	The maximum number of active client sessions accepted by the server
m_nMaxClientsPerAddress	The maximum number of clients per IP address accepted by the server
m_dwOptions	The options specified when creating an instance of the server
m_nPriority	The priority specified when creating an instance of the server
m_dwStackSize	The initial size of the stack allocated for threads created by the server
m_nTimeout	The timeout period in seconds waiting for a blocking operation to complete

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::m_nBacklog

```
UINT m_nBacklog;
```

The size of the backlog connection queue for the server.

Remarks

The **m_nBacklog** data member is a public variable that specifies the size of the queue allocated for pending client connections. A value of zero specifies that the queue should be set to a reasonable default value. On Windows server platforms, the maximum value is large enough to queue several hundred pending connections. Changing the value of this data member does not have an effect on an active instance of the server.

See Also

CInternetServer

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::m_nMaxClients

```
UINT m_nMaxClients;
```

The maximum number of clients that are permitted to connect to the server.

Remarks

The **m_nMaxClients** data member is a public variable that specifies the maximum number of clients that are permitted to establish a connection with the server. After this limit is reached, the server will reject additional connections until the number of active clients drops below this threshold. A value of zero specifies that there is no fixed limit on the active number of client connections. Changing the value of this data member does not have an effect on an active instance of the server. To change the maximum number of clients on an active server, use the **Throttle** method.

The actual number of client connections that can be accepted depends on the amount of memory available to the server process. Sockets are allocated from the non-paged memory pool, so the actual number of sockets that can be created system-wide depends on the amount of physical memory that is installed. If the server will be accessible over the Internet, it is recommended that you limit the maximum number of client connections to a reasonable value.

See Also

CInternetServer, Throttle

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::m_nMaxClientsPerAddress

```
UINT m_nMaxClientsPerAddress;
```

The maximum number of clients that are permitted to connect to the server from a single IP address.

Remarks

The **m_nMaxClientsPerAddress** data member is a public variable that specifies the maximum number of clients that are permitted to establish a connection with the server from a single IP address. After this limit is reached, the server will will reject additional connections until the number of active clients drops below this threshold. A value of zero specifies that there is no limit on the active number of client connections per IP address. Changing the value of this data member does not have an effect on an active instance of the server. To change the maximum number of clients on an active server, use the **Throttle** method.

See Also

CInternetServer, Throttle

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::m_dwOptions

```
DWORD m_dwOptions;
```

The default options used when starting an instance of the server.

Remarks

The **m_dwOptions** data member is a public variable that specifies the default options that should be used when starting an instance of the server. This variable can be modified directly or by calling the **SetOptions** method. For a list of available server options, see Server Option Constants. Changing the value of this data member does not have an effect on an active instance of the server.

See Also

CInternetServer, GetOptions, SetOptions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::m_nPriority

```
INT m_nPriority;
```

The priority specified when creating an instance of the server.

Remarks

The **m_nPriority** data member is a public variable that specifies the which specifies the priority for the server and all client sessions. Changing the value of this data member does not have an effect on an active instance of the server. It may be one of the following values:

Value	Description
INET_PRIORITY_NORMAL	The default priority which balances resource and processor utilization. It is recommended that most applications use this priority.
INET_PRIORITY_BACKGROUND	This priority significantly reduces the memory, processor and network resource utilization for the client session. It is typically used with lightweight services running in the background that are designed for few client connections. The client thread will be assigned a lower scheduling priority and will be frequently forced to yield execution to other threads.
INET_PRIORITY_LOW	This priority lowers the overall resource utilization for the client session and meters the processor utilization for the client session. The client thread will be assigned a lower scheduling priority and will occasionally be forced to yield execution to other threads.
INET_PRIORITY_HIGH	This priority increases the overall resource utilization for the client session and the thread will be given higher scheduling priority. It can be used when it is important for the client session thread to be highly responsive. It is not recommended that this priority be used on a system with a single processor.
INET_PRIORITY_CRITICAL	This priority can significantly increase processor, memory and network utilization. The thread will be given higher scheduling priority and will be more responsive to the remote host. It is not recommended that this priority be used on a system with a single processor.

See Also

CInternetServer, GetPriority, SetPriority

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::m_dwStackSize

```
DWORD m_dwStackSize;
```

The initial size of the stack allocated for threads created by the server.

Remarks

The **m_dwStackSize** data member is a public variable that specifies the initial amount of memory that is committed to the stack for each thread created by the server. A value of zero specifies that the default stack size should be used, which is 256K for 32-bit processes and 512K for 64-bit processes. This variable can be modified directly or by calling the **SetStackSize** method. Changing the value of this data member does not have an effect on an active instance of the server. It is recommended that most applications use the default stack size.

See Also

CInternetServer, GetStackSize, SetStackSize

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::m_nTimeout

```
DWORD m_nTimeout;
```

The default options used when starting an instance of the server.

Remarks

The **m_nTimeout** data member is a public variable that specifies the number of seconds the server should wait for a client to perform a network operation. If the client does not exchange any information with the server within this period of time, a timeout event will occur. The timeout value affects all clients that are connected to the server. This variable can be modified directly or by calling the **SetTimeout** method. Changing the value of this data member does not have an effect on an active instance of the server.

CInternetServer Class Methods

Class	Description
CInternetServer	Constructor which initializes the current instance of the class
~CInternetServer	Destructor which releases resources allocated by the class
Method	Description
Abort	Abort the connection and immediately close the socket
AsyncNotify	Enable or disable asynchronous notification of changes in server status
AttachHandle	Attach the specified server handle to this instance of the class
Broadcast	Write data to all active clients currently connected to the server
Cancel	Cancel a blocking operation for the specified client session
CompareAddress	Compare two IP addresses to determine if they are identical
DetachHandle	Detach the server handle from the current instance of this class
DisableSecurity	Disable secure communication with the client
DisableTrace	Disable logging of network function calls
Disconnect	Disconnect the client, closing the socket handle and terminating the session
EnableSecurity	Enable secure communication with the client
EnableTrace	Enable logging of network function calls to a file
EnumClients	Returns a list of active client connections established with the server
EnumNetworkAddresses	Return the list of network addresses that are configured for the local host
FindClient	Returns a handle to the client which matches the specified client ID or moniker
FormatAddress	Convert an IP address in binary format into a printable string
Flush	Flush the send and receive buffers for the specified client session
GetActiveClient	Return the socket handle for the active client session
GetAdapterAddress	Return the IP or MAC assigned to the specified network adapter
GetAddress	Convert an IP address string to a binary format
GetAddressFamily	Return the address family for the specified IP address
GetBacklog	Return the size of the backlog connection queue for the server
GetClientAddress	Return the IP address and port number for the specified client session
GetClientData	Returns the application defined data associated with the specified client session
GetClientHandle	Returns the handle for a specific client session based on its ID number
GetClientId	Returns the unique ID number assigned to the specified client session
GetClientIdleTime	Returns the amount of time the specified client session has been idle
GetClientMoniker	Returns the string alias associated with the specified client session
GetClientPort	Returns the remote port number used by the client to establish the connection
GetClientServer	Returns a socket handle to the server for the specified client socket
GetClientServerById	Returns a socket handle to the server for the specified session identifier

GetClientThreadId	Returns the thread ID for the specified client
GetClientThreads	Returns the number of client session threads created by the server
GetErrorString	Return a description for the specified error code
GetExternalAddress	Return the external IP address assigned to the local system
GetHandle	Return the client handle used by this instance of the class
GetHostAddress	Return the IP address assigned to the specified hostname
GetHostName	Return the hostname assigned to the specified IP address
GetLastError	Return the last error code
GetLocalAddress	Return the local IP address and port number for the server
GetLocalName	Return the hostname assigned to the local system
GetMemoryUsage	Return the amount of memory allocated for the server
GetOptions	Return the current server options
GetPriority	Return the current priority assigned to the server
GetStackSize	Return the initial size of the stack allocated for threads created by the server
GetStatus	Return the current status of the server
GetStreamInfo	Return information about the current stream I/O operation
GetThreadClient	Return the handle for the client session that is being managed by the specified thread
GetTimeout	Return the timeout interval for blocking operations in seconds
IsActive	Determine if the server is currently active
IsAddressNull	Determine if the specified IP address is a null address
IsAddressRoutable	Determine if the specified IP address is routable over the Internet
IsInitialized	Determine if the class has been successfully initialized
IsListening	Determine if the server is listening for client connections
IsLocked	Determine if the server is currently in a locked state
IsProtocolAvailable	Determine if the specified protocol and address family are supported
IsReadable	Determine if data is available to be read from the client
IsWritable	Determine if data can be sent to the client without causing the thread to block
Lock	Lock the server, causing all other client threads to block until it is unlocked
MatchHostName	Match a host name against one more strings that may contain wildcards
Peek	Read data from the client without removing it from the socket buffer
Read	Read data from the client
ReadLine	Read a line of data from the client, storing it in a string buffer
ReadStream	Read a stream of data from the client and store it in the specified buffer
Reject	Reject a pending client connection
Restart	Restart the server, terminating all active client sessions
Resume	Resume accepting client connections on the specified server
SetBacklog	Set the size of the backlog connection queue for the server

SetCertificate	Specify the server certificate that should be used with secure connections
SetClientData	Associate application defined data with the specified client session
SetClientMoniker	Associate a unique string alias with the specified client session
SetLastError	Set the last error code
SetOptions	Set one or more server options
SetPriority	Set the priority assigned to the server
SetTimeout	Set the timeout interval used when waiting for a blocking operation to complete
ShowError	Display a message box with a description of the specified error
Start	Begin listening for client connections on the specified address and port
Stop	Stop listening for connections and terminate all client sessions
StoreStream	Read a stream of data from the client and store it in a file
Suspend	Suspend accepting client connections and optionally reject or disconnect clients
Throttle	Limit the number of active client connections, connections per address and connection rate
Unlock	Unlock the server, allowing other client threads to resume execution
ValidateCertificate	Validate the specified security certificate is installed on the local system
Write	Write data to the client
WriteLine	Write a line of data to the client, terminated with a carriage-return and linefeed
WriteStream	Write a stream of data to the client

CInternetServer::CInternetServer Method

```
CInternetServer();
```

The **CInternetServer** constructor initializes the class library and validates the license key at runtime.

Remarks

If the constructor fails to validate the runtime license, subsequent methods in this class will fail. If the product is installed with an evaluation license, then the application will only function on the development system and cannot be redistributed.

The constructor calls the **InetInitialize** function to initialize the library, which dynamically loads other system libraries and allocates thread local storage. If you are using this class within another DLL, it is important that you do not create or destroy an instance of the class from within the **DllMain** function because it can result in deadlocks or access violation errors. You should not declare static or global instances of this class within another DLL if it is linked with the C runtime library (CRT) because it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

~CInternetServer, IsInitialized

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::~CInternetServer

```
~CInternetServer();
```

The **CInternetServer** destructor releases resources allocated by the current instance of the **CInternetServer** object. It also uninitializes the library if there are no other concurrent uses of the class.

Remarks

When a **CInternetServer** object goes out of scope, the destructor is automatically called to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all handles that were created for the connection are destroyed. If there are any clients connected to the server at the time the destructor is called, those client sessions will be immediately terminated.

The destructor is not called explicitly by the application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

CInternetServer::Abort Method

```
BOOL Abort(
   SOCKET hSocket
);

BOOL Abort();
```

Immediately close the socket without waiting for any remaining data to be written out.

Parameters

hSocket

An optional parameter that specifies the handle to the client socket. If this parameter is omitted, the socket handle for the active client session will be used. If this method is called outside of a server event handler, the socket handle must be specified.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **Abort** method should only be used when the connection must be closed immediately. This method should only be used to abort client connections and should not be called within an **OnAccept** event handler. To reject an incoming client connection, use the **Reject** method.

In most cases, the server should call the **Disconnect** method to gracefully close a client connection. Aborting the connection will discard any buffered data and may cause errors or result in unpredictable behavior by the client application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

CInternetServer::AsyncNotify Method

```
BOOL AsyncNotify(
   HWND hWnd,
   UINT uMsg
);
```

Enable or disable asynchronous notification of changes in server status.

Parameters

hWnd

A handle to the window whose window procedure will receive the notification message.

uMsg

The user-defined message that will be sent to the notification window.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **AsyncNotify** method is used by an application to enable or disable asynchronous notifications. The message window is typically the main UI window and these notifications are used signal to the application that it should update the user interface. If the ***hWnd*** parameter is not NULL, it must specify a valid window handle and the user-defined message must have a value of **WM_USER** or higher. The application cannot specify a notification message that is reserved by the operating system. The pseudo-handle **HWND_BROADCAST** cannot be specified as the notification window. If the ***hWnd*** parameter is NULL, notifications for the specified server will be disabled.

When asynchronous notifications are enabled for a server, the server will post the user-defined message to the window whenever there is a change in status or after a client has connected or disconnected from the server. The ***wParam*** message parameter will contain the notification message and the ***lParam*** message parameter will contain the handle to the server or the client ID. The following notification messages are defined:

Value	Description
INET_NOTIFY_STARTUP	This notification is sent when the server has started and is preparing to accept client connections. This notification is only sent once, and only if asynchronous notifications are enabled immediately after the **Start** method is called. This message will not be sent once the server has begun accepting client connections or when notification messages are disabled and then subsequently re-enabled at a later time. The ***lParam*** message parameter will specify the handle to the server.
INET_NOTIFY_LISTEN	This notification is sent when the server is listening for client connections. This notification message may be sent to the application multiple times over the lifetime of the server. If the server was suspended, this notification will be sent after the application calls the **Resume** method to resume

	accepting client connections. The ***lParam*** message parameter will specify the handle to the server.
INET_NOTIFY_SUSPEND	This notification is sent when the server suspends accepting new connections because the application has called the **Suspend** method. This notification message may be sent to the application multiple times over the lifetime of the server. The ***lParam*** message parameter will specify the handle to the server.
INET_NOTIFY_RESTART	This notification is sent when the server is restarted using the **Restart** method. Note that the server socket handle provided by the ***lParam*** message parameter will specify the new socket handle of the restarted server instance, not the original socket handle. The ***lParam*** message parameter will specify the handle to the server.
INET_NOTIFY_CONNECT	This notification is sent when the server accepts a client connection and the thread that manages the client session has begun processing network events for that client. This message notification will not be sent if the client connection is rejected by the server. The ***lParam*** message parameter will specify the unique ID of the client that connected to the server.
INET_NOTIFY_DISCONNECT	This notification is sent when the client disconnects from the server and the client socket has been closed. This notification message may not occur for each client session that is forced to terminate as the result of the server being stopped using the **Stop** method. The ***lParam*** message parameter will specify the unique ID of the client that disconnected from the server.
INET_NOTIFY_SHUTDOWN	This notification is sent when the server thread is in the process of terminating. At the time the application processes this notification message, the server handle in ***lParam*** will reference the defunct server and cannot be used with other server methods. The ***lParam*** message parameter will specify the handle to the server.

If asynchronous notifications are enabled, you should never use those notifications as a replacement for an event handler. When an event occurs, the callback function that handles the event is invoked in the context of the thread that manages the client session. The application should exchange data with the client within that event handler and not in response to a notification message. These notification messages should only be used to update the application UI in response to changes in the status of the server.

The INET_NOTIFY_CONNECT and INET_NOTIFY_DISCONNECT notifications are different from the other server notifications because the ***lParam*** message parameter does not specify the server handle, but rather the unique client ID associated with the session that connected to or disconnected from the server. If you need to obtain the handle to the client session using the ID, call the **GetClientHandle** method. To obtain the server handle in response to the INET_NOTIFY_CONNECT message, use the **GetClientServerById** method. Note that at the time the application processes the INET_NOTIFY_DISCONNECT notification message, the client session will have already terminated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

GetClientHandle, GetClientServerById

CInternetServer::AttachHandle Method

```
VOID AttachHandle(
   SOCKET hSocket
);
```

Attach the specified server socket handle to the current instance of the class.

Parameters

hSocket

The socket handle to the server that will be attached to the current instance of the class object.

Return Value

None.

Remarks

This method is used to attach a server handle created outside of the class using the SocketWrench API. Once the client handle is attached to the class, the other class member functions may be used with that server.

If a server handle has already been created for the class, that handle will be released when the new handle is attached to the class object. This will cause the server to stop and all client sessions will be terminated immediately. If you want to prevent the previous server from being stopped, you must call the **DetachHandle** method prior to attaching a new handle to the class instance.

Note that the ***hSocket*** parameter is presumed to be a valid server socket handle and no checks are performed to ensure that the handle references an active server. Specifying an invalid socket handle will cause subsequent method calls to fail.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

DetachHandle, GetHandle

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::Broadcast Method

```
INT Broadcast(
   LPBYTE lpBuffer,
   INT cbBuffer
);
```

Sends data to all clients that are connected to the server.

Parameters

lpBuffer

The pointer to the buffer which contains the data that is to be sent to the server clients.

cbBuffer

The number of bytes to send from the specified buffer.

Return Value

If the method succeeds, the return value is the number of clients that the data was sent to. If the method fails, the return value is INET_ERROR. To get extended error information, call the **GetLastError** method.

Remarks

The **Broadcast** method sends the contents of the buffer to all of the clients that are connected to the server. This method will block until all clients have been sent a copy of the data. There is no guarantee in which order the clients will receive and process the data that has been broadcast.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

Write, WriteLine

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::Cancel Method

```
BOOL Cancel(
   SOCKET hSocket
);
```

Cancel a blocking operation for the specified client session.

Parameters

hSocket

The handle to a client socket.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

When the **Cancel** method is called, the blocking method will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation using the same client socket handle. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

Canceling a blocking operation for another client session may yield unpredictable results. If you wish to terminate the client session, it is preferable to use the **Disconnect** method rather than using this method in conjunction with the **Abort** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

CInternetServer::CompareAddress Method

```
BOOL CompareAddress(
   LPINTERNET_ADDRESS lpAddress1,
   LPINTERNET_ADDRESS lpAddress2
);

BOOL CompareAddress(
   LPCTSTR lpszAddress1,
   LPCTSTR lpszAddress2
);
```

Compare two IP addresses to determine if they are identical.

Parameters

lpAddress1

A pointer to an INTERNET_ADDRESS structure that contains the first IP address to be compared. An alternate version of this method accepts a string that specifies the IP address to be compared.

lpAddress2

A pointer to an INTERNET_ADDRESS structure that contains the second IP address to be compared. An alternate version of this method accepts a string that specifies the IP address to be compared.

Return Value

If the method succeeds and the two addresses are identical, the return value is non-zero. If the method fails or the two addresses are not identical, the return value is zero. If either parameter is NULL, or the address family for the two addresses are not the same, the last error code will be updated. If the addresses are valid and in the same address family, but are not identical, the last error code will be set to NO_ERROR.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

GetClientAddress, INTERNET_ADDRESS

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::DetachHandle Method

```
SOCKET DetachHandle();
```

The **DetachHandle** method detaches the server socket handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the server socket associated with the current instance of the class object. If the server is not active, the value INVALID_SOCKET will be returned.

Remarks

This method is used to detach a server handle created by the class for use with the SocketWrench API. Once the server handle is detached from the class, no other class member functions may be called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

AttachHandle, GetHandle

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::DisableSecurity Method

```
BOOL DisableSecurity(
   SOCKET hSocket
);

BOOL DisableSecurity();
```

Disable secure communication with the client.

Parameters

hSocket

An optional parameter that specifies the handle to the client socket. If this parameter is omitted, the socket handle for the active client session will be used. If this method is called outside of a server event handler, the socket handle must be specified.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **DisableSecurity** method disables a secure session, with subsequent calls to **Read** and **Write** sending and receiving unencrypted data. It is important to note that because this method sends a shutdown message to terminate the secure session, this may cause connection to be closed by the remote host.

This method does not close the socket. Use the **Disconnect** method to close the socket and release the resources allocated for the client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

EnableSecurity, SetCertificate

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::DisableTrace Method

```
BOOL DisableTrace();
```

The **DisableTrace** method disables the logging of network function calls.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, a value of zero is returned.

Remarks

This method will disable output to the log file for the current thread or process, depending on the flags used when logging was enabled. If this method is not called, the resources that were allocated for the logging session will be released when the process ends.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

EnableTrace

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::Disconnect Method

```
BOOL Disconnect(
   SOCKET hSocket
);

BOOL Disconnect();
```

Disconnect the client, closing the socket handle and terminating the session.

Parameters

hSocket

An optional parameter that specifies the handle to the client socket. If this parameter is omitted, the socket handle for the active client session will be used. If this method is called outside of a server event handler, the socket handle must be specified.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is INET_ERROR. To get extended error information, call **GetLastError**.

Remarks

Once the connection has been terminated, the client socket handle is no longer valid and should no longer be used. Note that it is possible that the actual handle value may be re-used at a later point when a new connection is established. An application should always consider the socket handle to be opaque and never depend on it being a specific value.

This method sends an internal control message that notifies the server that this session should be terminated. When the session thread is signaled that it should terminate, it will begin to release the resources allocated for that session. To ensure that the client session terminates gracefully, there may be a brief period of time where the session thread is still active after this method has returned.

The **Disconnect** method should only be used to terminate client sessions and the server handle should never be provided as the ***hSocket*** parameter. To stop the server, use the **Stop** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

Abort, Stop

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::EnableSecurity Method

```
BOOL EnableSecurity(
   SOCKET hSocket
);

BOOL EnableSecurity();
```

Enable secure communication with the client.

Parameters

hSocket

An optional parameter that specifies the handle to the client socket. If this parameter is omitted, the socket handle for the active client session will be used. If this method is called outside of a server event handler, the socket handle must be specified.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is INET_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **EnableSecurity** method enables a secure communications session with the remote host, automatically negotiating the encryption algorithm and validating the certificate specified by a previous call to the **SetCertificate** method. This method will cause the calling thread to block and wait for the client to initiate the TLS handshake.

This method is typically used to implement support for explicit TLS connections, where the client establishes a standard, non-secure connection to the server and then negotiates a secure connection at a later point. Usually this is done by the client sending a specific command to the server, and the server calls **EnableSecurity** from within the **OnRead** event handler that processes the command. If the method succeeds, all subsequent calls to **Read** and **Write** to receive and send data will be encrypted.

This method is only used to enable a secure connection for a specific client session. If all client connections should be secure, then call the **SetOptions** method to specify the INET_OPTION_SECURE option prior to starting the server and call the **SetCertificate** method to specify the server certificate that should be used.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

DisableSecurity, SetCertificate, SetOptions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::EnableTrace Method

```
BOOL EnableTrace(
   LPCTSTR lpszTraceFile,
   DWORD dwTraceFlags
);
```

The **EnableTrace** method enables the logging of network function calls to a file.

Parameters

lpszTraceFile

A null-terminated string which specifies the name of the logfile which will be appended to or created. It is recommended that this file always specify an absolute path to avoid any ambiguity. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
TRACE_INFO	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
TRACE_ERROR	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
TRACE_HEXDUMP	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
TRACE_TRUNCATE	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.

Return Value

If the method succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the log file cannot be created.

Remarks

Logging is enabled and disabled at the process level and is not associated with a specific class instance. When logging is enabled, the information is appended to the specified file. If the file does not exist, it will be created. To limit the size of the file, enable and disable logging only around those sections of code that you wish to debug. If you do not provide a full path to the file, it will be relative to the current working directory for the process. This can produce unexpected results in multithreaded applications because the current directory is global to the entire process and can be changed by any thread at any time.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

The TRACE_HEXDUMP option can generate very large files because it includes all of the data exchanged between your application and the remote host. The TRACE_TRUNCATE option is only evaluated when logging is first enabled for a thread or process. If logging is already active, specifying this option will have no effect.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "`0x`". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxxx:xxxx::xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, a connection is being made to a system with the IPv4 address 192.0.0.1 on port 1234.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h

Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

CInternetServer::EnumClients Method

```
INT EnumClients(
   INTERNET_ADDRESS& ipAddress,
   SOCKET *lpClients,
   INT nMaxClients
);

INT EnumClients(
   LPCTSTR lpszAddress,
   SOCKET *lpClients,
   INT nMaxClients
);

INT EnumClients(
   SOCKET *lpClients,
   INT nMaxClients
);
```

Return a list of active client connections established with the server.

Parameters

ipAddress

A reference to an INTERNET_ADDRESS structure that contains the IP address that should be matched against the clients connected to the server. Only those clients that have connected to the server from this address will be returned in the ***lpClients*** array.

lpszAddress

A string that specifies the IP address that should be matched against the clients connected to the server. Only those clients that have connected to the server from this address will be returned in the ***lpClients*** array.

lpClients

Pointer to an array which will contain the socket handle for each active client session when the method returns. If this parameter is NULL, then the method will return the number of active client connections established with the server.

nMaxClients

Maximum number of socket handles to be returned in the ***lpClients*** array. If the ***lpClients*** parameter is NULL, this parameter should have a value of zero.

Return Value

If the method succeeds, the return value is the number of active client connections to the server. A return value of zero indicates that there are either no active client sessions, or no clients have connected using the specified IP address. If the method fails, the return value is FTP_ERROR. To get extended error information, call the **GetLastError** method.

Remarks

If the ***nMaxClients*** parameter is less than the number of active client connections, the method will fail. To dynamically determine the number of active connections, call the method with the ***lpClients*** parameter with a value of NULL, and the ***nMaxClients*** parameter with a value of zero.

This method will not enumerate clients that have disconnected from the server, even if the session thread is still active. If the server is in the process of shutting down, this method will return zero,

indicating no active client sessions, even though there may be clients that are still in the process of disconnecting from the server. To determine the actual number of client sessions regardless of their status, use the **GetClientThreads** method.

Example

```
// Populate a listbox with the IP address for each client
pListBox->ResetContent();

INT nClients = pServer->EnumClients();
if (nClients > 0)
{
    SOCKET *phClients = new SOCKET[nClients];

    nClients = pServer->EnumClients(phClients, nClients);
    if (nClients == INET_ERROR)
    {
        // Unable to obtain list of connected clients
        return;
    }

    for (INT nIndex = 0; nIndex < nClients; nIndex++)
    {
        CString strAddress;

        if (pServer->GetClientAddress(phClients[nIndex], strAddress))
            pListBox->AddString(strAddress);
    }

    // Free the memory allocated for the socket handles
    delete phClients;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

CInternetServer::EnumNetworkAddresses Method

```
INT EnumNetworkAddresses(
   INT nAddressFamily,
   LPINTERNET_ADDRESS lpAddressList,
   INT nMaxAddresses
);

INT EnumNetworkAddresses(
   LPINTERNET_ADDRESS lpAddressList,
   INT nMaxAddresses
);
```

The **EnumNetworkAddresses** method returns the list of network addresses that are configured for the local host.

Parameters

nAddressFamily

An integer which identifies the type of IP address that should be returned by this function. It may be one of the following values:

Value	Description
INET_ADDRESS_ANY	Return both IPv4 or IPv6 addresses for the local host, depending on how the system is configured and which network interfaces are enabled. This option is only recommended for applications that support IPv6.
INET_ADDRESS_IPV4	Specifies that the addresses should be in IPv4 format. The first four bytes of the *ipNumber* array are significant and contains the IP address. The remaining bytes are not significant and an application should not depend on them having any particular value, including zero.
INET_ADDRESS_IPV6	Specifies that the addresses should be in IPv6 format. All bytes in the *ipNumber* array are significant.

lpAddressList

A pointer to an array of INTERNET_ADDRESS structures that will contain the IP address of each local network interface.

nMaxAddresses

Maximum number of addresses to be returned.

Return Value

If the function succeeds, the return value is the number of network addresses that are configured for the local host. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

If the *nAddressFamily* parameter is specified as INET_ADDRESS_ANY, the application must be prepared to handle IPv6 addresses because it is possible that an IPv6 address string has been specified. For legacy applications that only recognize IPv4 addresses, the *nAddressFamily* member should always be specified as INET_ADDRESS_IPV4 to ensure that only IPv4 addresses are returned.

If this method is called without specifying the address family, the value INET_ADDRESS_IPV4 is used. This is provided primarily for compatibility with legacy applications and it is recommended that you explicitly specify the address family.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

CInternetServer::FindClient Method

```
SOCKET FindClient(
   UINT nClientId
);

SOCKET FindClient(
   LPCTSTR lpszMoniker
);
```

Returns a handle to the client which matches the specified client ID or moniker.

Parameters

nClientId

An unsigned integer the specifies a unique client ID for the session. This value must be greater than zero.

lpszMoniker

A null-terminated string which specifies the client moniker to search for. This parameter cannot be NULL and cannot specify an empty string.

Return Value

If the method succeeds, the return value is the handle to the client socket for the session that matches the specified client ID or moniker. If the method fails, the return value is INVALID_SOCKET. To get extended error information, call **GetLastError**.

Remarks

A client moniker is a string which can be used to uniquely identify a specific client session aside from its socket handle. A moniker can be assigned to the client session using the **SetClientMoniker** method. This method will search all active client sessions for the server, and returns the socket handle to the client that matches the specified moniker. If there is no match, an error will be returned.

The moniker can be any string value, however monikers are not case sensitive and may not contain embedded null characters. The maximum length of a moniker is 127 characters.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CInternetServer::Flush Method

```
BOOL Flush(
   SOCKET hSocket
);

BOOL Flush();
```

Flush the send and receive buffers for the specified client session.

Parameters

hSocket

An optional parameter that specifies the handle to the client socket. If this parameter is omitted, the socket handle for the active client session will be used. If this method is called outside of a server event handler, the socket handle must be specified.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **Flush** method will flush any data waiting to be read or written to the remote host . It is important to note that this method is not similar to flushing data to a disk file; it does not ensure that a specific block of data has been written to the socket. For example, you should never call this function immediately after calling the **Write** method or prior to calling the **Disconnect** method.

An application never needs to use the **Flush** method under normal circumstances. This method is only to be used when the application needs to immediately return the socket to an inactive state with no pending data to be read or written. Calling this function may result in data loss and should only be used if you understand the implications of discarding any data which has been sent by the client.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

IsReadable, IsWritable, Read, Write

CInternetServer::FormatAddress Method

```
INT FormatAddress(
   LPINTERNET_ADDRESS lpAddress,
   LPTSTR lpszAddress,
   INT cchAddress
);

INT FormatAddress(
   LPINTERNET_ADDRESS lpAddress,
   CString& strAddress
);
```

The **FormatAddress** method converts a numeric IP address to a printable string. The format of the string depends on whether an IPv4 or IPv6 address is specified.

Parameters

lpAddress

A pointer to an INTERNET_ADDRESS structure which specifies the numeric IP address that should be converted to a string.

lpszAddress

The buffer that will contain the formatted IP address. This buffer should be at least 46 characters in length. This may also reference a **CString** object which will contain the formatted address when the method returns.

cchAddress

The maximum number of characters that can be copied into the address buffer.

Return Value

If the method succeeds, the return value is the length of the IP address string. If the method fails, the return value is INET_ERROR, meaning that the IP address could not be converted into a string. Typically this indicates that the pointer to the INTERNET_ADDRESS structure is invalid, or the data does not specify a valid IP address family.

Remarks

The format and length of IPv4 and IPv6 address strings are very different. An IPv4 address string looks like "192.168.0.20", while an IPv6 address string can look something like "fd7c:2f6a:4f4f:ba34::a32". If your application checks for the format of these address strings, it needs to be aware of the differences. You also need to make sure that you're providing enough space to display or store an address to avoid buffer overruns.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::GetActiveClient Method

```
SOCKET GetActiveClient();
```

Return the socket handle for the active client session.

Parameters

None.

Return Value

If the method succeeds, the return value is the socket handle for the active client session. If the method fails, the return value is INVALID_SOCKET. To get extended error information, call the **GetLastError** method.

Remarks

The **GetActiveClient** method returns a handle to the client socket for the active client session. The active session is determined by the session thread that is currently executing, and therefore is only meaningful within the context of a server event handler such as **OnConnect** or **OnRead**. The value returned by the his method is the same as the client socket handle that is passed to the event handler.

This method will fail within an **OnAccept** event handler because at that point the connection has not yet been accepted, therefore there is no active client session. It will also fail if called outside of an event handler. To obtain the socket handle associated with a particular session thread, use the **GetThreadClient** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

CInternetServer::GetAdapterAddress Method

```
INT GetAdapterAddress(
   INT nAdapterIndex,
   INT nAddressType,
   LPTSTR lpszAddress,
   INT nMaxLength
);

INT GetAdapterAddress(
   INT nAdapterIndex,
   INT nAddressType,
   CString& strAddress
);
```

Return the IP or MAC assigned to the specified network adapter.

Parameters

nAdapterIndex

An integer value that identifies the network adapter.

nAddressType

An integer value which specifies the type of address that should be returned:

Value	Description
INET_ADAPTER_IPV4	The address string will contain the primary IPv4 unicast address assigned to the network adapter.
INET_ADAPTER_IPV6	The address string will contain the primary IPv6 unicast address assigned to the network adapter.
INET_ADAPTER_MAC	The address string will contain the media access control (MAC) address assigned to the network adapter.

lpszAddress

A string buffer that will contain the IP or MAC address assigned to the adapter. This parameter cannot be NULL and it is recommended that it be at least 64 characters in length to provide enough space for any address type. An alternate form of the method accepts a **CString** argument which will contain the address.

nMaxLength

The maximum number of characters that can be copied into the string buffer, including the terminating null character. If the buffer is too small to store the complete address, this method will fail.

Return Value

If the method succeeds, the return value is the number of characters copied to the string buffer, not including the terminating null character. A return value of zero indicates that the requested address type has not been assigned to the adapter. If the method fails, the return value is INET_ERROR and this typically indicates that either the adapter index is invalid or the string buffer is not large enough to store the complete address. To get extended error information, call **GetLastError**.

Remarks

The **GetAdapterAddress** method will return the IPv4, IPv6 or MAC address assigned to a specific network adapter. The primary network adapter has an index value of zero, and it increments for each adapter that is configured on the local system.

The media access control (MAC) address is a 48 bit or 64 bit value that is assigned to each network interface and is used for identification and access control. All network devices on the same subnet must be assigned their own unique MAC address. Unlike IP addresses which may be assigned dynamically and can be frequently changed, MAC addresses are considered to be more permanent because they are usually assigned by the device manufacturer and stored in firmware. Note that in some cases it is possible to change the address assigned to a device, and virtual network interfaces may have configurable MAC addresses.

This method returns the MAC address string as sequence of hexadecimal values separated by a colon. An example of a 48 bit MAC address would be "01:23:45:67:89:AB". Note that some virtual network adapters may not have a MAC address assigned to them, in which case this method would return zero.

This method will ignore network adapters that have been disabled, as well as those that are bound to a virtual loopback interface. If the system has dial-up networking or virtualization software installed, this method may also return IP addresses assigned to a virtualized network adapters installed by that software.

Example

```
// Display the IPv4 address assigned to each network adapter
for (INT nIndex = 0;; nIndex++)
{
    CString strAddress;

    if (pServer->GetAdapterAddress(nIndex, INET_ADAPTER_IPV4, strAddress) ==
INET_ERROR)
        break;

    _tprintf(_T("Adapter %d: %s\n"), nIndex, szAddress);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

EnumNetworkAddresses, GetLocalAddress, GetLocalName

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::GetAddress Method

```
INT GetAddress(
   LPCTSTR lpszAddress,
   INT nAddressFamily,
   LPINTERNET_ADDRESS lpAddress
);

INT GetAddress(
   LPCTSTR lpszAddress,
   LPINTERNET_ADDRESS lpAddress
);
```

The **GetAddress** method converts an IP address string to binary format.

Parameters

lpszAddress

A null-terminated string which specifies an IP address. This method recognizes the format for both IPv4 and IPv6 format addresses.

nAddressFamily

An integer which identifies the type of IP address specified by the ***lpszAddress*** parameter. It may be one of the following values:

Value	Description
INET_ADDRESS_UNKNOWN	Return the IP address for the specified host in either IPv4 or IPv6 format, depending on the value of the ***lpszAddress*** parameter.
INET_ADDRESS_IPV4	Specifies that the address should be in IPv4 format. The first four bytes of the ***ipNumber*** array are significant and contains the IP address. The remaining bytes are not significant and an application should not depend on them having any particular value, including zero. If the ***lpszAddress*** parameter does not specify a valid IPv4 address string, this method will fail.
INET_ADDRESS_IPV6	Specifies that the address should be in IPv6 format. All bytes in the ***ipNumber*** array are significant. If the ***lpszAddress*** parameter does not specify a valid IPv6 address string, this method will fail.

lpAddress

A pointer to an INTERNET_ADDRESS structure that will contain the IP address.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is INET_ERROR. To get extended error information, call **GetLastError**.

Remarks

If the ***nAddressFamily*** parameter is specified as INET_ADDRESS_UNKNOWN, the application must be prepared to handle IPv6 addresses because it is possible that an IPv6 address string has been specified. For legacy applications that only recognize IPv4 addresses, the ***nAddressFamily*** member

should always be specified as INET_ADDRESS_IPV4 to ensure that only IPv4 addresses are returned and any attempt to specify an IPv6 address string would result in an error.

To determine if the local system has an IPv6 TCP/IP stack installed and configured on the local system, use the **IsProtocolAvailable** method. If an IPv6 stack is not installed, this method will fail if the ***lpszAddress*** parameter specifies an IPv6 address, even if the address itself is valid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

FormatAddress, IsAddressNull, IsAddressRoutable, IsProtocolAvailable, INTERNET_ADDRESS

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::GetAddressFamily Method

```
INT GetAddressFamily(
   LPCTSTR lpszAddress,
);
```

Return the address family for the specified IP address.

Parameters

lpszAddress

A null-terminated string which specifies an IP address. This method recognizes the format for both IPv4 and IPv6 format addresses.

Return Value

If the method succeeds, the return value is the address family for the specified IP address and may be one of the values listed below. If the method fails, the return value is INET_ADDRESS_UNKNOWN. To get extended error information, call the **GetLastError** method.

Value	Description
INET_ADDRESS_IPV4	The address passed to the method is a valid IPv4 address.
INET_ADDRESS_IPV6	The address passed to the method is a valid IPv6 address.

Remarks

The **GetAddressFamily** method returns the address family associated with the specified IP address string. This can be used to determine if a string specifies a valid IPv4 or IPv6 address that can be passed to other methods such as **Connect**. Note that this method will not attempt to resolve hostnames, it will only accept IP addresses.

To determine if the local system has an IPv6 TCP/IP stack installed and configured on the local system, use the **IsProtocolAvailable** method. If an IPv6 stack is not installed, this method will fail if the *lpszAddress* parameter specifies an IPv6 address, even if the address itself is valid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

IsAddressNull, IsAddressRoutable, IsProtocolAvailable, INTERNET_ADDRESS

CInternetServer::GetBacklog Method

```
UINT GetBacklog();
```

Return the size of the backlog connection queue for the server.

Parameters

None.

Return Value

The return value is the size of the queue used to accept client connections.

Remarks

The **GetBacklog** method returns the size of the queue allocated for pending client connections. A value of zero specifies that the size of the queue should be set to a reasonable default value. On Windows server platforms, the maximum value is large enough to queue several hundred pending connections. To change the size of the backlog queue, use the **SetBacklog** method prior to starting the server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

CInternetServer::GetClientAddress Method

```
INT GetClientAddress(
   SOCKET hSocket,
   LPINTERNET_ADDRESS lpAddress,
   UINT *lpnRemotePort
);

INT GetClientAddress(
   SOCKET hSocket,
   LPTSTR lpszAddress,
   INT nMaxLength
);

INT GetClientAddress(
   SOCKET hSocket,
   CString& strAddress
);
```

Return the IP address and port number for the specified client session.

Parameters

hSocket

An optional parameter that specifies the handle to a server or client socket. If this parameter is omitted, the socket handle for the active client session will be used. If this method is called outside of a server event handler, the socket handle must be specified.

lpAddress

A pointer to an INTERNET_ADDRESS structure that will contain the IP address of the client that is connected to the server. This parameter may be NULL, in which case the IP address will not be returned to the caller.

lpnRemotePort

A pointer to an unsigned integer that will contain the port number of the client that is connected to the server. This parameter may be NULL, in which case the port number will not be returned to the caller.

lpszAddress

A null-terminated string buffer that will contain the formatted IP address, terminated with a null character. To accommodate both IPv4 and IPv6 addresses, this buffer should be at least 46 characters in length.

nMaxLength

The maximum number of characters that can be copied into the address buffer.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is INET_ERROR. To get extended error information, call **GetLastError**.

Remarks

If this method is called within an **OnAccept** event handler, passing the server handle as the ***hSocket*** parameter will return the IP address and port number for the client that is attempting to establish the connection. If the client address is unavailable, the ***ipFamily*** member of the INTERNET_ADDRESS structure will be zero.

The format and length of IPv4 and IPv6 address strings are very different. An IPv4 address string looks like "192.168.0.20", while an IPv6 address string can look something like "fd7c:2f6a:4f4f:ba34::a32". If your application checks for the format of these address strings, it needs to be aware of the differences. You also need to make sure that you're providing enough space to display or store an address to avoid buffer overruns.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

CInternetServer::GetClientData Method

```
BOOL GetClientData(
   SOCKET hClient,
   LPVOID *lppvData
);

BOOL GetClientData(
   LPVOID *lppvData
);
```

Returns the application defined data associated with the specified client session.

Parameters

hClient

An optional parameter that specifies the handle to the client socket. If this parameter is omitted, the socket handle for the active client session will be used. If this method is called outside of a server event handler, the socket handle must be specified.

lppvData

A pointer to a void pointer which will contain an application defined value associated with the client session.

Return Value

If the method succeeds, the return value is non-zero. A return value of zero indicates that application defined data for the client session could not be retrieved. To get extended error information, call **GetLastError**.

Remarks

The **GetClientData** method is used to retrieve the application defined data that was previously associated with a client session using the **SetClientData** method. This is typically used to associate a pointer to a data structure or a class instance with a specific client handle.

This method can only be used with client socket handles created using the server interface. If the socket handle is invalid, or does not reference a client socket handle created by the server, the *lppvData* pointer passed to this method will be initialized to a value of NULL and the method will return a value of zero.

If this method is called with a valid socket handle and there is no data associated with the socket, the method will return a non-zero value and the *lppvData* pointer will be returned with a NULL value. Before dereferencing the pointer returned by this method, the application should always check the return value to ensure the method succeeded and make sure that the pointer is not NULL.

Example

```
UINT *pnValue1 = new UINT;
UINT *pnValue2 = NULL;

*pnValue1 = 1234;

if (!pServer->SetClientData(hClient, pnValue1))
{
    // Unable to associate the data with this session
    return;
}
```

```
if (!pServer->GetClientData(hClient, (LPVOID *)&pnValue2))
{
    // Unable to retrieve the data associated with this session
    return;
}

// pnValue2 == pnValue1
printf("The value of the user defined data is %u\n", *pnValue2);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

SetClientData

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::GetClientHandle Method

```
SOCKET GetClientHandle(
   UINT nClientId
);
```

Returns the handle for a specific client session based on its ID number.

Parameters

nClientId

An unsigned integer value which uniquely identifies the client session.

Return Value

If the method succeeds, the return value is the socket handle for the specified client session. If the method fails, the return value is INVALID_SOCKET. To get extended error information, call **GetLastError**.

Remarks

Each client connection that is accepted by the server is assigned a unique numeric value called the client ID. The **GetClientHandle** method will return the socket handle that is associated with the specified client ID. Unlike socket handles, which are reused by the operating system, the client ID is guaranteed to be unique throughout the lifetime of the server. To obtain the ID associated with the client session, use the **GetClientId** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

GetClientId, GetClientMoniker, SetClientMoniker, GetThreadClient

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::GetClientId Method

```
UINT GetClientId(
   SOCKET hSocket
);

UINT GetClientId();
```

Returns the unique ID number assigned to the specified client session.

Parameters

hSocket

An optional parameter that specifies the handle to the client socket. If this parameter is omitted, the socket handle for the active client session will be used. If this method is called outside of a server event handler, the socket handle must be specified.

Return Value

If the method succeeds, the return value is an unsigned integer value which uniquely identifies the client session. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

Each client connection that is accepted by the server is assigned a unique numeric value. This value can be obtained by calling the **GetClientId** method and used by the application to identify that client session. The **GetClientHandle** method can then be used to used to obtain the client socket handle for the session, based on that client ID. It is important to note that the actual value of the client ID should be considered opaque. It is only guaranteed that the value will be greater than zero, and that it will be unique to the client session.

While it is possible for a client socket handle to be reused by the operating system, client IDs are unique throughout the life of the server session and are never duplicated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

CInternetServer::GetClientIdleTime Method

```
DWORD GetClientIdleTime(
   SOCKET hSocket
);

DWORD GetClientIdleTime();
```

Returns the number of milliseconds that the specified client session has been idle.

Parameters

hSocket

An optional parameter that specifies the handle to the client socket. If this parameter is omitted, the socket handle for the active client session will be used. If this method is called outside of a server event handler, the socket handle must be specified.

Return Value

If the method succeeds, the return value is an unsigned integer value which specifies the number of milliseconds the client session has been idle. If the method fails, the return value is INFINITE. To get extended error information, call **GetLastError**.

Remarks

The **GetClientIdleTime** method will return the number of milliseconds that have elapsed since data was exchanged with the client. The elapsed time is limited to the resolution of the system timer, which is typically in the range of 10 milliseconds to 16 milliseconds.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

GetClientHandle, GetClientId, GetClientMoniker, GetTimeout

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::GetClientMoniker Method

```
INT GetClientMoniker(
   SOCKET hClient,
   LPTSTR lpszMoniker,
   INT nMaxLength
);

INT GetClientMoniker(
   SOCKET hClient,
   CString& strMoniker
);
```

The **GetClientMoniker** method returns the moniker associated with the specified client session.

Parameters

hSocket

An optional parameter that specifies the handle to the client socket. If this parameter is omitted, the socket handle for the active client session will be used. If this method is called outside of a server event handler, the socket handle must be specified.

lpszMoniker

Pointer to a string buffer that will contain the moniker for the specified client session when the method returns. An alternate version of this method accepts a **CString** object if it is available.

nMaxLength

The maximum number of characters that may be copied into the string buffer. The buffer must be large enough to store the moniker and a terminating null character. The maximum length of a moniker is 127 characters.

Return Value

If the method succeeds, the return value is the number of characters in the moniker string. A return value of zero specifies that no moniker was assigned to the socket. If the method fails, the return value is INET_ERROR. To get extended error information, call **GetLastError**.

Remarks

A client moniker is a string which can be used to uniquely identify a specific client session aside from its socket handle. A moniker can be assigned to the client session using the **SetClientMoniker** method. This method will return the moniker that was previously assigned to the client, if any. To obtain the socket handle associated with a given moniker, use the **FindClient** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

CInternetServer::GetClientPort Method

```
INT GetClientPort(
   SOCKET hSocket
);

INT GetClientPort();
```

Returns the remote port number used by the client to establish the connection.

Parameters

hSocket

An optional parameter that specifies the handle to the client socket. If this parameter is omitted, the socket handle for the active client session will be used. If this method is called outside of a server event handler, the socket handle must be specified.

Return Value

If the method succeeds, the return value is the port number. If the method fails, the return value is INET_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetClientPort** method returns the remote port number that the client is bound to. Note that this is not the port number that the server is using to listen for connections, it is the port number that the client is bound to on the remote host. Typically this is an ephemeral port, either in the range of 1025 through 5000, or greater than 32768, depending on the client operating system.

If this method is called within the **OnAccept** event handler, providing the server socket handle as the *hSocket* parameter will return the port number of the client that is attempting to establish the connection.

It is not recommended that you use the client port number for anything other than informational and logging purposes. Do not make any assumptions about the specific port number or range of port numbers that a client is using when establishing a connection to the server. The ephemeral port number that a client is bound to can vary based on the client operating system.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

GetClientAddress, OnAccept, OnConnect

CInternetServer::GetClientServer Method

```
SOCKET HttpGetClientServer(
    UINT nClientId
);
```

The **GetClientServer** method returns a handle to the server that created the specified client session.

Parameters

nClientId

An unsigned integer which uniquely identifies the client session.

Return Value

If the method succeeds, the return value is the handle to the server that created the client session. If the method fails, the return value is INVALID_SOCKET. To get extended error information, call the **GetLastError** method.

Remarks

The **GetClientServer** method returns the handle to the server that created the client session and is typically used within a notification message handler. If the server is in the process of shutting down, or the client session thread is terminating, this method will fail and return INVALID_SOCKET indicating that the session ID is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

AsyncNotify

CInternetServer::GetClientServerById Method

```
SOCKET GetClientServerById(
    UINT nClientId
);
```

The **GetClientServerById** method returns a socket handle to the server for the specified client session identifier.

Parameters

nClientId

Client session identifier.

Return Value

If the method succeeds, the return value is the handle to the server that created the client session. If the method fails, the return value is INVALID_SOCKET. To get extended error information, call the **GetLastError** method.

Remarks

The **GetClientServerById** method returns the handle to the server that created the client session using the client's unique identifier. The **GetClientServer** method can be used to obtain the server handle using the client socket handle rather than the client session ID. This method is typically used in conjunction with the INET_NOTIFY_CONNECT notification message to obtain the handle to the server that generated the event using the client ID passed in the ***wParam*** message parameter.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

CInternetServer::GetClientThreadId Method

```
DWORD GetClientThreadId(
   SOCKET hSocket
);

DWORD GetClientThreadId();
```

Returns the thread ID associated with the specified client.

Parameters

hSocket

An optional parameter that specifies the handle to the client socket. If this parameter is omitted, the socket handle for the active client session will be used. If this method is called outside of a server event handler, the socket handle must be specified.

Return Value

If the method succeeds, the return value is a thread ID. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **GetClientThreadId** method returns a thread ID that can be used to identify the thread that is managing the client session. The thread ID can be used with other Windows API functions such as **OpenThread**. Exercise caution when using thread-related functions, interfering with the normal operation of the thread can have unexpected results. You should never use this method to obtain a thread handle and then call the **TerminateThread** function to terminate a client session. This will prevent the thread from releasing the resources that were allocated for the session and can leave the server in an unstable state. To terminate a client session, use the **Disconnect** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

EnumClients, GetActiveClient

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::GetClientThreads Method

```
INT GetClientThreads();
```

Returns the number of client session threads created by the server.

Parameters

None.

Return Value

If the method succeeds, the return value is the number of client session threads that have been created by the server. If the method fails, the return value is INET_ERROR. To get extended error information, call the **GetLastError** method.

Remarks

The **InetGetClientThreads** function returns the number of threads that are managing client sessions for the specified server. If there are no clients connected to the server, this function will return a value of zero. Because this function returns the number of session threads, the value returned will include those clients that are in the process of disconnecting from the server but their session thread has not yet terminated. This differs from the **InetEnumServerClients** function which will only enumerate active clients.

If you wish to determine when the last client has disconnected from the server, call this function within an event handler for the INET_EVENT_DISCONNECT event. If the function returns a value greater than one, then there are other client sessions that are either connected or in the process of terminating.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

CInternetServer::GetErrorString Method

```
INT GetErrorString(
   DWORD dwErrorCode,
   LPTSTR lpszDescription,
   INT nMaxLength
);

INT GetErrorString(
   DWORD dwErrorCode,
   CString& strDescription
);
```

The **GetErrorString** method is used to return a description of a specific error code. Typically this is used in conjunction with the **GetLastError** method for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

The buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length. An alternate form of the method accepts a **CString** variable which will contain the error description.

nMaxLength

The maximum number of characters that may be copied into the description buffer.

Return Value

If the method succeeds, the return value is the length of the description string. If the method fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the method is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

CInternetServer::GetExternalAddress Method

```
INT GetExternalAddress(
   INT nAddressFamily,
   LPINTERNET_ADDRESS lpAddress,
   INT nMaxLength
);

INT GetExternalAddress(
   INT nAddressFamily,
   LPTSTR lpszAddress,
   INT nMaxLength
);

INT GetExternalAddress(
   INT nAddressFamily,
   CString& strAddress
);
```

The **GetExternalAddress** method returns the external IP address for the local system.

Parameters

nAddressFamily

An integer which identifies the type of IP address that should be returned by this function. It may be one of the following values:

Value	Description
INET_ADDRESS_IPV4	Specifies that the address should be in IPv4 format. The method will attempt to determine the external IP address using an IPv4 network connection.
INET_ADDRESS_IPV6	Specifies that the address should be in IPv6 format. The method will attempt to determine the external IP address using an IPv6 network connection and requires that the local host have an IPv6 network interface installed and enabled.

lpAddress

A pointer to an INTERNET_ADDRESS structure that will contain the external IP address of the local host in binary form.

lpszAddress

A null-terminated string buffer that will contain the external IP address of the local host.

nMaxLength

The maximum length of the string that will contain the IP address when the method returns.

Return Value

In the first form of the method, if it succeeds, the return value is the IP address of the local system in numeric form. If the method fails, the return value is INET_ADDRESS_NONE. In the second form, the return value is the length of the IP address string and an error is indicated by the return value INET_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetExternalAddress** method returns the IP address assigned to the router that connects the local host to the Internet. This is typically used by an application executing on a system in a local network that uses a router which performs Network Address Translation (NAT). In that network configuration, the **GetLocalAddress** method will only return the IP address for the local system on the LAN side of the network unless a connection has already been established to a remote host. The **GetExternalAddress** function can be used to determine the IP address assigned to the router on the Internet side of the connection and can be particularly useful for servers running on a system behind a NAT router.

This method requires that you have an active connection to the Internet and calling this function on a system that uses dial-up networking may cause the operating system to automatically connect to the Internet service provider. An application should always check the return value in case there is an error; never assume that the return value is always a valid address. The function may be unable to determine the external IP address for the local host for a number of reasons, particularly if the system is behind a firewall or uses a proxy server that restricts access to external sites on the Internet. If the function is able to obtain a valid external address for the local host, that address will be cached by the library for sixty minutes. Because dial-up connections typically have different IP addresses assigned to them each time the system is connected to the Internet, it is recommended that this function only be used with broadband connections where a NAT router is being used.

Calling this function may cause the current thread to block until the external IP address can be resolved and should never be used in conjunction with asynchronous socket connections. If you need to call this function in an application which uses asynchronous sockets, it is recommended that you create a new thread and call this function from within that thread.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

CInternetServer::GetHandle Method

```
SOCKET GetHandle();
```

The **GetHandle** method returns the socket handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the socket handle associated with the current instance of the class object. If there is no active connection, the value INVALID_SOCKET will be returned.

Remarks

This method is used to obtain the client handle created by the class for use with the SocketWrench API.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

AttachHandle, DetachHandle, IsInitialized

CInternetServer::GetHostAddress Method

```
INT GetHostAddress(
   LPCTSTR lpszHostName,
   INT nAddressFamily,
   LPINTERNET_ADDRESS lpAddress
);

INT GetHostAddress(
   LPCTSTR lpszHostName,
   LPINTERNET_ADDRESS lpAddress
);
```

The **InetGetHostAddress** method resolves the specified host name into an IP address in binary format.

Parameters

lpszHostName

The name of the host to resolve; this may be a fully-qualified domain name or an IP address. This method recognizes the format for both IPv4 and IPv6 format addresses.

nAddressFamily

An integer which identifies the type of IP address to return. It may be one of the following values:

Value	Description
INET_ADDRESS_UNKNOWN	Return the IP address for the specified host in either IPv4 or IPv6 format, depending on how the host name can be resolved. By default, a preference will be given for returning an IPv4 address. However, if the host only has an IPv6 address, that value will be returned.
INET_ADDRESS_IPV4	Specifies that the address should be returned in IPv4 format. The first four bytes of the *ipNumber* array are significant and contains the IP address. The remaining bytes are not significant and an application should not depend on them having any particular value, including zero.
INET_ADDRESS_IPV6	Specifies that the address should be returned in IPv6 format. All bytes in the *ipNumber* array are significant. Note that it is possible for an IPv6 address to actually represent an IPv4 address. This is indicated by the first 10 bytes of the address being zero.

lpAddress

A pointer to an INTERNET_ADDRESS structure that will contain the IP address of the specified host.

Return Value

If the method succeeds, the return value is zero. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

This method can also be used to convert an address in dot notation to a binary format. If the method must perform a DNS lookup to resolve the hostname, the calling thread will block. To ensure future

compatibility with IPv6 networks, it is important that the application does not make any assumptions about the format of the address. If the function returns successfully, the ***ipFamily*** member of the **INTERNET_ADDRESS** structure should always be checked to determine the type of address.

The ***nAddressFamily*** parameter is used to specify a preference for the type of address returned, however it is possible that a host may not have an IPv4 or IPv6 address record, in which case this function will fail. Although IPv4 is still the most common address used at this time, an application should not assume that because a given host name does not have an IPv4 address, that the host name is invalid.

If the ***nAddressFamily*** parameter is specified as INET_ADDRESS_UNKNOWN, the application must be prepared to handle IPv6 addresses because it is possible for a host name to have an IPv6 address assigned to it and no IPv4 address. For legacy applications that only recognize IPv4 addresses, the ***nAddressFamily*** member should always be specified as INET_ADDRESS_IPV4 to ensure that only IPv4 addresses are returned.

To determine if the local system has an IPv6 TCP/IP stack installed and configured on the local system, use the **IsProtocolAvailable** method. If an IPv6 stack is not installed, this method will fail if the ***lpszHostName*** parameter specifies an host that only has an IPv6 (AAAA) DNS record.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetClientAddress, GetHostName, GetLocalAddress, GetLocalName, IsProtocolAvailable, INTERNET_ADDRESS

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::GetHostName Method

```
INT GetHostName(
   LPINTERNET_ADDRESS lpAddress,
   LPTSTR lpszHostName,
   INT cchHostName
);

INT GetHostName(
   LPINTERNET_ADDRESS lpAddress,
   CString& strHostName
);
```

The **GetHostName** method performs a reverse lookup, returning the host name associated with a given IP address.

Parameters

lpAddress

A pointer to an INTERNET_ADDRESS structure which specifies the IP address that should be resolved into a host name.

lpszHostName

The buffer that will contain the host name. It is recommended that this buffer be at least 256 characters in length to accommodate the longest possible fully qualified domain name. This parameter cannot be NULL. An alternate form of the method accepts a **CString** argument which will contain the hostname.

cchHostName

The maximum number of characters that can be copied into the buffer.

Return Value

If the method succeeds, the return value is the length of the hostname. If the method fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

If the method must perform a reverse DNS lookup to resolve the IP address into a host name, the calling thread will block. This method requires that the host have a PTR record, otherwise it will fail. Because many hosts do not have a PTR record, calling this method frequently may have a negative impact on the overall performance of the application.

To determine if the local system has an IPv6 TCP/IP stack installed and configured on the local system, use the **IsProtocolAvailable** method. If an IPv6 stack is not installed, this method will fail if the *lpAddress* parameter specifies an IPv6 address, even if the address itself is valid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

CInternetServer::GetLastError Method

```
DWORD GetLastError();

DWORD GetLastError(
   CString& strDescription
);
```

Parameters

strDescription

A string which will contain a description of the last error code value when the method returns. If no error has been set, or the last error code has been cleared, this string will be empty.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **SetLastError** method. The Return Value section of each reference page notes the conditions under which the method sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **GetLastError** method immediately when a method's return value indicates that an error has occurred. That is because some methods call **SetLastError**(0) when they succeed, clearing the error code set by the most recently failed method.

Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_SOCKET or INET_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

The description of the error code is the same string that is returned by the **GetErrorString** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

CInternetServer::GetLocalAddress Method

```
INT GetLocalAddress(
   LPINTERNET_ADDRESS lpAddress,
   UINT *lpnPort
);

INT GetLocalAddress(
   LPTSTR lpszAddress,
   INT nMaxLength
);

INT GetLocalAddress(
   CString& strAddress
   UINT *lpnPort
);
```

Return the local IP address and port number for the server.

Parameters

lpAddress

A pointer to an INTERNET_ADDRESS structure that will contain the IP address of the local host. If the server is not active, this function will attempt to determine the IP address of the local host assigned by the system. If the address is not required, this parameter may be NULL.

lpszAddress

A null-terminated string that will contain the IP address of the local host. If this version of the method is used, the IP address is converted to a string format using the **FormatAddress** method. The string should be able to store at least 46 characters to ensure that both IPv4 and IPv6 formatted addresses can be returned without the possibility of a buffer overrun. An alternate form of the method accepts a **CString** argument which will contain the line of text returned by the server.

lpnPort

A pointer to an unsigned integer that will contain the local port number. If the server is active, this parameter will be set to the local port that the listening socket was bound to. If the server is not active, this parameter is ignored. If the port number is not required, this parameter may be NULL.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is INET_ERROR. To get extended error information, call **GetLastError**.

Remarks

To ensure future compatibility with IPv6 networks, it is important that the application does not make any assumptions about the format of the address. If the function returns successfully, the *ipFamily* member of the **INTERNET_ADDRESS** structure should always be checked to determine the type of address.

If the system is connected to the Internet through a local network and/or uses a router that performs Network Address Translation (NAT), the **GetLocalAddress** method will return the local, non-routable IP address assigned to the local system. To determine the public IP address has been assigned to the system, you should use the **GetExternalAddress** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CInternetServer::GetLocalName Method

```
INT GetLocalName(
   LPTSTR lpszHostName,
   INT cchHostName
);

INT GetLocalName(
   CString& strHostName
);
```

The **GetLocalName** method returns the hostname assigned to the local system.

Parameters

lpszHostName

The buffer that will contain the hostname. This parameter cannot be NULL. An alternate form of the method accepts a **CString** argument which will contain the local hostname.

cchHostName

The maximum number of characters that can be copied into the address buffer.

Return Value

If the method succeeds, the return value is the length of the hostname. If the method fails, the return value is INET_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetClientAddress, GetLocalAddress

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::GetMemoryUsage Method

```
SIZE_T GetMemoryUsage();
```

Return the amount of memory allocated for the server.

Parameters

None.

Return Value

If the method succeeds, the return value is the number of bytes allocated. If the method fails, the return value is zero. Call the **GetLastError** method to determine the cause of the failure.

Remarks

This method returns the amount of memory allocated for the server. It enumerates all heap allocations made by the process and returns the total number of bytes allocated for the server and all client sessions. This value only reflects the amount of memory explicitly allocated by this class library and does not reflect the total working set size of the process, or memory allocated by any other libraries. To determine the working set size for the process, refer to the Win32 **GetProcessWorkingSetSize** and **GetProcessMemoryInfo** functions.

This method forces the server into a locked state, and all network operations will block until the method returns. Because this method enumerates all heaps created for the process, it can be an expensive operation, particularly when a large number of connections have been established. Frequent use of this method can significantly degrade the performance of the application. It is primarily intended for use as a debugging tool to determine if memory usage is the result of an increase in active client sessions. If the value returned by the method remains reasonably constant, but the amount of memory allocated for the process continues to grow, it could indicate a memory leak in some other area of the application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::GetOptions Method

```
DWORD GetOptions();
```

Return the current server options.

Parameters

None.

Return Value

This method returns an unsigned integer value that specifies the server options that are currently enabled for the class instance. For a list of the available options, see Server Option Constants. This method returns the value of the **m_dwOptions** class member variable.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

CInternetServer::GetPriority Method

```
INT GetPriority();
```

Return the current priority assigned to the specified server.

Parameters

None.

Return Value

If the method succeeds, the return value is the priority for the specified server. If the method fails, the return value is INET_PRIORITY_INVALID. To get extended error information, call the **GetLastError** method.

Remarks

The **GetPriority** method can be used to determine the current priority assigned to the server. It will return one of the following values:

Value	Description
INET_PRIORITY_BACKGROUND	This priority significantly reduces the memory, processor and network resource utilization for the server. It is typically used with lightweight services running in the background that are designed for few client connections. The server thread will be assigned a lower scheduling priority and will be frequently forced to yield execution to other threads.
INET_PRIORITY_LOW	This priority lowers the overall resource utilization for the server and meters the processor utilization for the server thread. The server thread will be assigned a lower scheduling priority and will occasionally be forced to yield execution to other threads.
INET_PRIORITY_NORMAL	The default priority which balances resource and processor utilization. This is the priority that is initially assigned to the server when it is started, and it is recommended that most applications use this priority.
INET_PRIORITY_HIGH	This priority increases the overall resource utilization for the server and the thread will be given higher scheduling priority. It is not recommended that this priority be used on a system with a single processor.
INET_PRIORITY_CRITICAL	This priority can significantly increase processor, memory and network utilization. The server thread will be given higher scheduling priority and will be more responsive to client connection requests. It is not recommended that this priority be used on a system with a single processor.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

CInternetServer::GetStackSize Method

```
DWORD GetStackSize();
```

Return the initial size of the stack allocated for threads created by the server.

Parameters

None.

Return Value

If the method succeeds, the return value is the amount of memory that will be allocated for the stack in bytes. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetStackSize** method returns the initial amount of memory that is committed to the stack for each thread created by the server. By default, the stack size for each thread is set to 256K for 32-bit processes and 512K for 64-bit processes.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

CInternetServer::GetStatus Method

```
INT GetStatus();
```

Return the current status of the server.

Parameters

None.

Return Value

An integer value that specifies the server status.

Remarks

The return value is one of the following values:

Value	Description
INET_SERVER_INACTIVE	The server is currently inactive.
INET_SERVER_STARTED	The server has initialized and is preparing to listen for client connections.
INET_SERVER_LISTENING	The server is actively listening for incoming client connections.
INET_SERVER_SUSPENDED	The server has been suspended and is no longer accepting client connections.
INET_SERVER_SHUTDOWN	The server has been stopped and is in the process of terminating all active client connections.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

CInternetServer::GetStreamInfo Method

```
BOOL GetStreamInfo(
   SOCKET hSocket
   LPINETSTREAMINFO lpStreamInfo
);

BOOL GetStreamInfo(
   LPINETSTREAMINFO lpStreamInfo
);
```

The **GetStreamInfo** function fills a structure with information about the current stream I/O operation.

Parameters

hSocket

An optional parameter that specifies the handle to the client socket. If this parameter is omitted, the socket handle for the active client session will be used. If this method is called outside of a server event handler, the socket handle must be specified.

lpSecurityInfo

A pointer to an **INETSTREAMINFO** structure which contains information about the status of the current operation.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetStreamInfo** method returns information about the current streaming socket operation, including the average number of bytes transferred per second and the estimated amount of time until the operation completes. If there is no operation currently in progress, this method will return the status of the last successful streaming read or write performed by the client.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

CInternetServer::GetThreadClient Method

```
SOCKET WINAPI InetGetThreadClient(
    DWORD dwThreadId
);
```

The **GetThreadClient** method returns the socket handle for the client session that is being managed by the specified thread.

Parameters

dwThreadId

An unsigned integer value which identifies the thread managing the client session. If this parameter has a value of zero, then the client handle for the current thread is returned.

Return Value

If the method succeeds, the return value is the socket handle for the specified client session. If the method fails, the return value is INVALID_SOCKET. To get extended error information, call **InetGetLastError**.

Remarks

The **GetThreadClient** is used to obtain the socket handle for the client session that is being managed by the specified thread. If the specified thread ID is zero, then the method will return the client socket for the current thread, otherwise it will search the internal table of all active client sessions and return the handle to the session that is being managed by that thread.

This method will fail if the thread ID does not specify an active client session thread.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

CInternetServer::GetTimeout Method

```
INT GetTimeout();
```

Return the timeout interval for blocking network operations in seconds.

Parameters

None.

Return Value

The return value is the timeout period in seconds. If there is no active server, this will return the timeout period that will be used when the server is started. A value of zero specifies that a reasonable default timeout period will be automatically selected.

Remarks

The **GetTimeout** method returns the number of seconds the server will wait for a blocking network operation to complete, such as sending or receiving data. This value also determines the amount of time that the server will wait for the client to send data before invoking the **OnTimeout** event handler for that session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

CInternetServer::IsActive Method

```
BOOL IsActive();
```

Determine if the server has been started.

Return Value

This method returns a non-zero value if the server has been started. If the server is stopped this method will return zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::IsAddressNull Method

```
BOOL IsAddressNull(
   LPCTSTR lpszAddress
);

BOOL IsAddressNull(
   LPINTERNET_ADDRESS lpAddress
);
```

The **IsAddressNull** method determines if the IP address is null.

Parameters

lpszAddress

A string that specifies the IP address.

lpAddress

A pointer to an INTERNET_ADDRESS structure that specifies the IP address.

Return Value

If the method succeeds and the IP address is null, or the parameter is a NULL pointer, the return value is non-zero. If the method fails or the address is not null, the return value is zero. If the address family is not supported, the last error code will be updated. If the address is valid but not null, the last error code will be set to NO_ERROR.

Remarks

A null IP address is one where all bits for the address (32 bits for IPv4 or 128 bits for IPv6) are zero. This is a special address that is typically used when creating a passive socket that should listen for connections on all available network interfaces.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

GetAddress, IsAddressRoutable, INTERNET_ADDRESS

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::IsAddressRoutable Method

```
BOOL IsAddressRoutable(
   LPCTSTR lpszAddress
);
```

```
BOOL IsAddressRoutable(
   LPINTERNET_ADDRESS lpAddress
);
```

The **IsAddressRoutable** method determines if the IP address is routable over the Internet.

Parameters

lpszAddress

A string that specifies the IP address.

lpAddress

A pointer to an INTERNET_ADDRESS structure that specifies the IP address.

Return Value

If the method succeeds and the IP address is routable over the Internet, the return value is non-zero. If the method fails or the address is not routable, the return value is zero. If the parameter is NULL, or the address family is not supported, the last error code will be updated. If the address is valid but not routable, the last error code will be set to NO_ERROR.

Remarks

A routable IP address is one that can be reached by anyone over the public Internet. These are also commonly referred to as "public addresses" which are typically assigned to networks and individual hosts by an Internet service provider. There are also certain addresses that are not routable over the Internet, and used to address systems over a local network or private intranet. This function can be used to determine if a given IP address is public (routable) or private.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

CInternetServer::IsInitialized Method

```
BOOL IsInitialized();
```

The **IsInitialized** method returns whether or not the class object has been successfully initialized.

Parameters

None.

Return Value

This method returns a non-zero value if the class object has been successfully initialized. A return value of zero indicates that the runtime license key could not be validated or the networking library could not be loaded by the current process.

Remarks

When an instance of the class is created, the class constructor will attempt to initialize the component with the runtime license key that was created when SocketTools was installed. If the constructor is unable to validate the license key or load the networking libraries, this initialization will fail.

If SocketTools was installed with an evaluation license, the application cannot be redistributed to another system. The class object will fail to initialize if the application is executed on another system, or if the evaluation period has expired. To redistribute your application, you must purchase a development license which will include the runtime key that is needed to redistribute your software to other systems. Refer to the Developer's Guide for more information.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

CInternetServer, IsListening, IsLocked

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::IsListening Method

```
BOOL IsListening();
```

Determine if the server is listening for client connections.

Parameters

None.

Return Value

If the server has started and is listening for client connections, the method returns a non-zero value. If the server is not listening for connections, the return value is zero.

Remarks

The **IsListening** method determines if the server has been started and is actively listening for incoming connection requests from client applications. This method will return zero if the server is not active, if it has been suspended using the **Suspend** method or if the **Stop** method has been called to shutdown the server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

IsActive, Start, Stop, Suspend

CInternetServer::IsLocked Method

```
BOOL IsLocked();
```

Determine if the server is currently in a locked state.

Parameters

None.

Return Value

If the server is locked, the method returns a non-zero value. If the server is not locked, the return value is zero.

Remarks

The **IsLocked** method determines if a server has been locked using the **Lock** method. Only the thread that has locked the server may interact with it and all other threads will block when they attempt to perform a network operation. After the server is unlocked, the blocked threads will resume normal execution. If the application has created multiple instances of the **CInternetServer** class, this method will return a non-zero value if any of those servers have been locked, not only the current instance.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

CInternetServer::IsProtocolAvailable Method

```
BOOL IsProtocolAvailable(
   INT nAddressFamily,
   INT nProtocol
);
```

The **IsProtocolAvailable** method determines if the operating system supports creating a socket for the specified address family and protocol.

Parameters

nAddressFamily

An integer which identifies the address family that should be checked. It should be one of the following values:

Value	Description
INET_ADDRESS_IPV4	Specifies that the function should determine if it can create an Internet Protocol version 4 (IPv4) socket. This requires that the system have an IPv4 TCP/IP stack bound to at least one network adapter on the local system. All Windows systems include support for IPv4 by default.
INET_ADDRESS_IPV6	Specifies that the function should determine if it can create an Internet Protocol version 6 (IPv6) socket. This requires that the system have an IPv6 TCP/IP stack bound to at least one network adapter on the local system. Windows XP and Windows Server 2003 includes support for IPv6, however it is not installed by default. Windows Vista and later versions include support for IPv6 and enable it by default.

nProtocol

An integer which identifies the protocol that should be checked. It should be one of the following values:

Value	Description
INET_PROTOCOL_TCP	Specifies the Transmission Control Protocol. This protocol provides a reliable, bi-directional byte stream. This requires that the system be capable of creating a stream socket using the specified address family.
INET_PROTOCOL_UDP	Specifies the User Datagram Protocol. This protocol is message oriented, sending data in discrete packets. This requires that the system be capable of creating a datagram socket using the specified address family.

Return Value

If the system is capable of creating a socket using the specified address family and protocol, this method will return a non-zero value. If the combination of address family and protocol is not supported, this method will return a value of zero.

Remarks

The **IsProtocolAvailable** method is used to determine if the operating system supports creating a particular type of socket. Typically it is used by an application to determine if the system has an IPv6 TCP/IP stack installed and configured. By default, all Windows systems will have an IPv4 stack installed if the system has a network adapter. However, not all systems may have an IPv6 stack installed, particularly older Windows XP and Windows Server 2003 systems. Note that if an IPv6 stack is not installed, the library will not recognize IPv6 addresses and cannot resolve host names that only have an IPv6 (AAAA) record, even if the address or host name is valid.

Example

```
if (!pSocket->IsProtocolAvailable(INET_ADDRESS_IPV6, INET_PROTOCOL_TCP))
{
    AfxMessageBox(_T("This system does not support IPv6"), MB_ICONEXCLAMATION);
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

GetAddress, GetHostAddress, GetHostName

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::IsReadable Method

```
BOOL IsReadable();

BOOL IsReadable(
   SOCKET hSocket
);

BOOL IsReadable(
   SOCKET hSocket,
   INT nTimeout,
   LPDWORD lpdwAvail
);
```

The **IsReadable** method is used to determine if data is available to be read from the client.

Parameters

hSocket

An optional parameter that specifies the handle to the client socket. If this parameter is omitted, the socket handle for the active client session will be used. If this method is called outside of a server event handler, the socket handle must be specified.

nTimeout

Timeout for remote host response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

lpdwAvail

A pointer to an unsigned integer which will contain the number of bytes available to read. This parameter may be NULL if this information is not required.

Return Value

If the server can read data from the client within the specified timeout period, the method returns a non-zero value. If there is no data available to be read, the method returns zero.

Remarks

On some platforms, this value will not exceed the size of the receive buffer (typically 64K bytes). Because of differences between TCP/IP stack implementations, it is not recommended that your application exclusively depend on this value to determine the exact number of bytes available. Instead, it should be used as a general indicator that there is data available to be read.

If the connection is secure, the value returned in ***lpdwAvail*** will reflect the number of bytes available in the encrypted data stream. The actual amount of data available to the application after it has been decrypted will vary.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

IsWritable, Peek, Read, ReadLine, ReadStream

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::IsWritable Method

```
BOOL IsWritable(
   INT nTimeout
);
```

The **IsWritable** method is used to determine if data can be written to the remote host.

Parameters

nTimeout

Timeout for remote host response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

Return Value

If data can be sent to the client within the specified timeout period, the method returns a non-zero value. The method will return zero if the socket send buffer is full.

Remarks

The **IsWritable** method cannot be used to determine the amount of data that can be sent to the client without blocking the current thread. A non-zero return value only indicates that the send buffer is not full and can accept some data. In most cases, it is recommended that larger blocks of data be broken into smaller logical blocks rather than attempting to send it all of the data at once. For very large streams of data, it is recommended that you use the **WriteStream** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

IsReadable, Write, WriteLine, WriteStream

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::Lock Method

```
BOOL Lock();
```

Lock the server, causing other client threads to block until it is unlocked.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **Lock** method causes the specified server to enter a locked state where only the current thread may interact with the server and the clients that are connected to it. While a server is locked, all other threads will block when they attempt to perform a network operation. When the server is unlocked, the blocked threads will resume normal execution.

This method should be used carefully, and a server should never be left in a locked state for an extended period of time. It is meant to be used when the server process updates a global data structure and it must prevent any other threads from performing a network operation during the update. Only one server can be locked at any one time, and once a server has been locked, it can only be unlocked by the same thread.

The program should always check the return value from this method, and should never assume that the lock has been established. If more than one thread attempts to lock a server at the same time, there is no guarantee as to which thread will actually establish the lock. If a potential deadlock situation is detected, this method will fail and return a value of zero.

Every time the **Lock** method is called, an internal lock counter is incremented, and the lock will not be released until the lock count drops to zero. This means that each call to the **Lock** method must be matched by an equal number of calls to the **Unlock** method. Failure to do so will result in the server becoming non-responsive as it remains in a locked state.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

IsLocked, Unlock

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::MatchHostName Method

```
BOOL MatchHostName(
   LPCTSTR lpszHostName,
   LPCTSTR lpszHostMask
   BOOL bResolve
);
```

The **MatchHostName** method matches a host name against one more strings that may contain wildcards.

Parameters

lpszHostName

A null-terminated string which specifies the host name or IP address to match.

lpszHostMask

A null-terminated string which specifies one or more values to match against the host name. The asterisk character can be used to match any number of characters in the host name, and the question mark can be used to match any single character. Multiple values may be specified by separating them with a semicolon.

bResolve

A boolean value which specifies if the host name or IP address should be resolved when matching the host against the mask string. If this parameter is non-zero, two checks against the host mask string will be performed; once for the host name specified and once for its IP address. If this parameter is zero, then the match is made only against the host name string provided.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **MatchHostName** method provides a convenient way for an application to determine if a given host name matches one or more mask strings which may contain wildcard characters. For example, the host name could be "www.microsoft.com" and the host mask string could be "*.microsoft.com". In this example, the method would return a non-zero value indicating the host name matched the mask. However, if the mask string was "*.net" then the method would return zero, indicating that there was no match. Multiple mask values can be combined by separating them with a semicolon; for example, the mask "*.com;*.org" would match any host name in either the .com or .org top-level domains.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CInternetServer::Peek Method

```
INT Peek(
   SOCKET hSocket,
   LPBYTE lpBuffer,
   INT cbBuffer
);

INT Peek(
   LPBYTE lpBuffer,
   INT cbBuffer
);
```

Read data from the client without removing it from the socket buffer.

Parameters

hSocket

An optional parameter that specifies the handle to the client socket. If this parameter is omitted, the socket handle for the active client session will be used. If this method is called outside of a server event handler, the socket handle must be specified.

lpBuffer

Pointer to the buffer in which the data will be stored. This argument may be NULL, in which case no data is copied from the socket buffers, however the function will return the number of bytes available to read.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. If the ***lpBuffer*** parameter is not NULL, this value must be greater than zero.

Return Value

If the function succeeds, the return value is the number of bytes available to read from the socket. A return value of zero indicates that there is no data available to read at that time. If the function fails, the return value is INET_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **Peek** method returns data that is available to read from the socket, up to the number of bytes specified. The data returned by this method is not removed from the socket buffers. It must be consumed by a subsequent call to the **Read** method. The return value indicates the number of bytes that can be read in a single operation, up to the specified buffer size. However, it is important to note that it may not indicate the total amount of data available to be read from the socket at that time.

If no data is available to be read, the method will return a value of zero. To determine if there is data available to be read, use the **IsReadable** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

IsReadable, IsWritable, Read, ReadLine, Write, WriteLine

CInternetServer::PreProcessEvent Method

```
virtual LONG PreProcessEvent(
    SOCKET hServer,
    UINT nClientId,
    UINT nEventId,
    DWORD dwError,
    BOOL& bHandled
);
```

A virtual method that is invoked for each event generated by the server.

Parameters

hServer

The server handle. The application should treat this as an opaque value that is only valid as long as the server is active. This value should not be stored by the application and the handle value will change if the server is restarted.

nClientId

An unsigned integer which uniquely identifies the client that has issued a request to the server. This value is guaranteed to be unique to the client session throughout the life of the server and is never reused. The application should never make assumptions about the order in which IDs are allocated to the client sessions.

nEventId

An unsigned integer which specifies which event occurred. For a list of events, see Server Event Constants.

dwError

An unsigned integer which specifies any error that occurred. If no error occurred, then this parameter will be zero.

bHandled

An integer which specifies if the event has been handled by the application. If this parameter is set to a non-zero value, the default event handler will not be invoked for the event.

Return Value

The method should return a value of zero to indicate that the default event handler should be invoked for the event. If the method returns a non-zero value, this value is passed back to the event dispatcher and the default handler will not be invoked.

Remarks

The **PreProcessEvent** method is invoked for each event that is generated, prior to the default handler for that event. To implement an event handler, the application should create a class derived from the **CInternetServer** class, and then override this method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::Read Method

```
INT Read(
   SOCKET hSocket,
   LPBYTE lpBuffer,
   INT cbBuffer
);

INT Read(
   LPBYTE lpBuffer,
   INT cbBuffer
);
```

Read data from the client.

Parameters

hSocket

An optional parameter that specifies the handle to the client socket. If this parameter is omitted, the socket handle for the active client session will be used. If this method is called outside of a server event handler, the socket handle must be specified.

lpBuffer

Pointer to the buffer in which the data will be stored. This parameter cannot be NULL.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

Return Value

If the method succeeds, the return value is the number of bytes read. A return value of zero indicates that the client has closed the connection and there is no more data available to be read. If the method fails, the return value is INET_ERROR. To get extended error information, call the **GetLastError** method.

Remarks

The **Read** method will read up to the specified number of bytes and store the data in the buffer provided by the caller. If there is no data available to be read at the time this method is invoked, the session thread will block until at least one byte of data becomes available, the timeout period elapses or an error occurs. This method will return if any amount of data is sent by the client, and will not block until the entire buffer has been filled.

The application should never make an assumption about the amount of data that will be available to read. TCP considers all data to be an arbitrary stream of bytes and does not impose any structure on the data itself. For example, if the client is sending data to the server in fixed 512 byte blocks of data, it is possible that a single call to the **Read** method will return only a partial block of data, or it may return multiple blocks combined together. It is the responsibility of the application to buffer and process this data appropriately.

For applications that are built using the Unicode character set, it is important to note that the buffer is an array of bytes, not characters. If the client is sending string data to the server, it must be read as a stream of bytes and converted using the **MultiByteToWideChar** function. If the client is sending lines of text terminated with a linefeed or carriage return and linefeed pair, the **ReadLine** method will return a line of text at a time and perform this conversion for you.

To determine if there is data available to be read without causing the session thread to block, call the **IsReadable** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

IsReadable, IsWritable, Peek, ReadLine, Write, WriteLine

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::ReadLine Method

```
BOOL ReadLine(
   SOCKET hSocket,
   LPTSTR lpszBuffer,
   LPINT lpnLength
);

BOOL ReadLine(
   LPTSTR lpszBuffer,
   LPINT lpnLength
);

BOOL ReadLine(
   SOCKET hSocket,
   CString& strBuffer,
   INT nMaxLength
);

BOOL ReadLine(
   CString& strBuffer,
   INT nMaxLength
);
```

Read up to a line of data from the socket and return it in a string buffer.

Parameters

hSocket

An optional parameter that specifies the handle to the client socket. If this parameter is omitted, the socket handle for the active client session will be used. If this method is called outside of a server event handler, the socket handle must be specified.

lpszBuffer

Pointer to the string buffer that will contain the data when the method returns. The string will be terminated with a null character, and will not contain the end-of-line characters. An alternate form of the method accepts a **CString** argument which will contain the line of text returned by the server.

lpnLength

A pointer to an integer value which specifies the length of the buffer. The value should be initialized to the maximum number of characters that can be copied into the string buffer, including the terminating null character. When the method returns, its value will updated with the actual length of the string.

nMaxLength

An integer value which specifies the maximum length of the buffer.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **ReadLine** method reads data from the socket and copies into a specified string buffer. Unlike the **Read** method which reads arbitrary bytes of data, this method is specifically designed to return a

single line of text data in a string. When an end-of-line character sequence is encountered, the method will stop and return the data up to that point. The string buffer is guaranteed to be null-terminated and will not contain the end-of-line characters. This method will force the thread to block until an end-of-line character sequence is processed, the read operation times out or the remote host closes its end of the socket connection.

There are some limitations when using **ReadLine**. The method should only be used to read text, never binary data. In particular, the method will discard nulls, linefeed and carriage return control characters. The Unicode version of this method will return a Unicode string, however it does not support reading raw Unicode data from the socket. Any data read from the socket is internally buffered as octets (eight-bit bytes) and converted to Unicode using the **MultiByteToWideChar** function.

The **Read** and **ReadLine** method calls can be intermixed, however be aware that **Read** will consume any data that has already been buffered by the **ReadLine** method and this may have unexpected results.

Unlike the **Read** method, it is possible for data to be returned in the string buffer even if the return value is zero. Applications should check the length of the string to determine if any data was copied into the buffer. For example, if a timeout occurs while the method is waiting for more data to arrive on the socket, it will return zero; however, data may have already been copied into the string buffer prior to the error condition. It is the responsibility of the application to process that data, regardless of the return value.

Example

```
CString strBuffer;
BOOL bResult;

do
{
    bResult = pServer->ReadLine(strBuffer);

    if (strBuffer.GetLength() > 0)
    {
        // Process the line of data returned in the string
        // buffer; the string is always null-terminated
    }
} while (bResult);

DWORD dwError = pServer->GetLastError();

if (dwError == ST_ERROR_CONNECTION_CLOSED)
{
    // The remote host has closed its side of the connection and
    // there is no more data available to be read
}
else if (dwError != 0)
{
    // An error has occurred while reading a line of data
}

CInternetServer::ReadStream Method

```
BOOL ReadStream(
   SOCKET hSocket,
   LPVOID lpvBuffer,
   LPDWORD lpdwLength,
   DWORD dwOptions,
   LPBYTE lpMarker,
   DWORD cbMarker
);

BOOL ReadStream(
   LPVOID lpvBuffer,
   LPDWORD lpdwLength,
   DWORD dwOptions,
   LPBYTE lpMarker,
   DWORD cbMarker
);
```

Read a stream of data from the client and store it in the specified buffer.

Parameters

hSocket

An optional parameter that specifies the handle to the client socket. If this parameter is omitted, the socket handle for the active client session will be used. If this method is called outside of a server event handler, the socket handle must be specified.

lpvBuffer

Pointer to the buffer that will contain or reference the data when the method returns. The actual argument depends on the value of the ***dwOptions*** parameter which specifies how the data stream will be stored.

lpdwLength

A pointer to an unsigned integer value which specifies the maximum length of the buffer and contains the number of bytes read when the method returns. This argument should should always point to an initialized value. If the lpvBuffer argument specifies a memory buffer, then this argument cannot point to an initialized value of zero; if any other type of stream buffer is used and the initialized value is zero, that indicates that all available data from the socket should be returned until the end-of-stream marker is encountered or the remote host disconnects.

dwOptions

An unsigned integer value which specifies both the stream buffer type and any options to be used when reading the data stream.

Value	Description
INET_STREAM_DEFAULT	The default stream buffer type is determined by the value passed as the ***lpvBuffer*** parameter. If the argument specifies a pointer to a global memory handle initialized to NULL, then the method will return a handle which references the data; otherwise, the method will consider the parameter a pointer to a block of pre-allocated memory which will contain the stream data when the method returns. In most cases, it is recommended that an application explicitly specify the stream

	buffer type rather than using the default value.
INET_STREAM_MEMORY	The ***lpvBuffer*** argument specifies a pointer to a pre-allocated block of memory which will contain the data read from the socket when the method returns. If this stream buffer type is used, the ***lpdwLength*** argument must point to an unsigned integer which has been initialized with the maximum length of the buffer.
INET_STREAM_HGLOBAL	The ***lpvBuffer*** argument specifies a pointer to a global memory handle. When the method returns, the handle will reference a block of memory that contains the stream data. The application should take care to make sure that the handle passed to the method does not currently reference a valid block of memory; it is recommended that the handle be initialized to NULL prior to calling this method.
INET_STREAM_HANDLE	The ***lpvBuffer*** argument specifies a Windows handle to an open file, console or pipe. This should be the same handle value returned by the **CreateFile** function in the Windows API. The data read from the socket will be written to this handle using the WriteFile function.
INET_STREAM_SOCKET	The ***lpvBuffer*** argument specifies a socket handle. The data read from the socket specified by the ***hSocket*** argument will be written to this socket. The socket handle passed to this method must have been created by this library; if it is a socket created by an third-party library or directly by the Windows Sockets API, you should either create another instance of the class and attach the socket using the **AttachHandle** method or use the INET_STREAM_HANDLE stream buffer type instead.
INET_STREAM_CONVERT	The data stream is considered to be textual and will be modified so that end-of-line character sequences are converted to follow standard Windows conventions. This will ensure that all lines of text are terminated with a carriage-return and linefeed sequence. Because this option modifies the data stream, it should never be used with binary data. Using this option may result in the amount of data returned in the buffer to be larger than the source data. For example, if the source data only terminates a line of text with a single linefeed, this option will have the effect of inserting a carriage-return character before each linefeed.
INET_STREAM_UNICODE	The data stream should be converted to Unicode. This option should only be used with text data, and will result in the stream data being returned as 16-bit wide characters rather than 8-bit bytes. The amount of data returned will be twice the amount read from the source data stream; if the application is using a pre-allocated memory buffer, this must be considered before calling this method.

lpMarker

A pointer to an array of bytes which marks the end of the data stream. When this byte sequence is encountered by the method, it will stop reading and return to the caller. The buffer will contain all of the data read from the socket up to and including the end-of-stream marker. If this argument is NULL, then the method will continue to read from the socket until the maximum buffer size is reached, the remote host closes its socket or an error is encountered.

cbMarker

An unsigned integer value which specifies the length of the end-of-stream marker in bytes. If the *lpMarker* parameter is NULL, then this value must be zero.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **ReadStream** method enables an application to read an arbitrarily large stream of data and store it in memory, write it to a file or even another socket. Unlike the **Read** method, which will return immediately when any amount of data has been read, **ReadStream** will only return when the buffer is full as specified by the *lpdwLength* parameter, the logical end-of-stream marker has been read, the socket closed by the remote host or when an error occurs. This method will force the session thread to block until the operation completes.

It is possible for data to be returned in the buffer even if the method returns a value of zero. Applications should also check the value of the *lpdwLength* argument to determine if any data was copied into the buffer. For example, if a timeout occurs while the method is waiting for more data to arrive on the socket, it will return zero; however, data may have already been copied into the buffer prior to the error condition. It is the responsibility of the application to process that data, regardless of the method return value.

Example

```
HGLOBAL hgblBuffer = NULL; // Return data in a global memory buffer
DWORD cbBuffer = 102400;   // Read up to 100K bytes
BOOL bResult;

bResult = pServer->ReadStream(&hgblBuffer, &cbBuffer,
                              INET_STREAM_HGLOBAL | INET_STREAM_CONVERT);

if (bResult && cbBuffer > 0)
{
    LPBYTE lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // Use data in the stream buffer

    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

CInternetServer::Reject Method

```
BOOL Reject();
```

Reject a pending client connection.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **Reject** method rejects a pending client connection and the remote host will see this as the connection being aborted. If there are no pending client connections at the time, this method will immediately return with an error indicating that the operation would cause the server thread to block. This method should only be invoked from within an **OnAccept** event handler if the application wishes to reject the incoming connection before a client session is created.

To determine the IP address of a client that is attempting to connect to the server from within the **OnAccept** event, use the **GetClientAddress** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

GetClientAddress, OnAccept

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::Restart Method

```
BOOL Restart();
```

Restart the server, terminating all active client sessions.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **Restart** method will restart the specified server, terminating all active client sessions. If the method is unable to restart the server for any reason, the server thread is terminated. The server retains all of the options specified for the previous instance.

If an application calls this method from within an event handler, the active client session (the client for which the event handler was invoked) may not get a disconnect notification. It is recommended that this method only be called by the same thread that created the server using the **Start** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

Start, Stop

CInternetServer::Resume Method

```
BOOL Resume();
```

Resume accepting client connections.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **Resume** method instructs the server to resume accepting new client connections after the **Suspend** method has been called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

Restart, Start, Stop, Suspend, Throttle

CInternetServer::SetBacklog Method

```
BOOL SetBacklog(
   UINT nBacklog
);
```

Set the size of the backlog connection queue for the server.

Parameters

nBacklog

An integer value that specifies the size of the connection backlog queue.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero.

Remarks

The **SetBacklog** method specifies the size of the queue allocated for pending client connections. A value of zero specifies that the queue should be set to a reasonable default value. On Windows server platforms, the maximum value is large enough to queue several hundred pending connections. This method should only be called prior to invoking the **Start** method, it does not have any effect on an active server. To get the current size of the backlog queue, use the **GetBacklog** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CInternetServer::SetCertificate Method

```
BOOL SetCertificate(
   DWORD dwProtocol,
   LPCTSTR lpszCertStore,
   LPCTSTR lpszCertName,
   LPCTSTR lpszPassword
);

BOOL SetCertificate(
   LPCTSTR lpszCertStore,
   LPCTSTR lpszCertName,
   LPCTSTR lpszPassword
);

BOOL SetCertificate(
   LPCTSTR lpszCertName,
   LPCTSTR lpszPassword
);
```

Specify the server certificate that should be used with secure connections.

Parameters

dwProtocol

An optional bitmask of supported security protocols. If this parameter is not specified, then a default set of security protocols will be automatically selected. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
SECURITY_PROTOCOL_DEFAULT	The default selection of security protocols will be used when establishing a connection. The TLS 1.2, TLS 1.1 and TLS 1.0 protocols will be negotiated with the client, in that order of preference. This option will always request the latest version of the preferred security protocols and is the recommended value.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the client. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Note that SSL 2.0 has been deprecated and will never be used by default.
SECURITY_PROTOCOL_TLS	The TLS 1.0, 1.1 or 1.2 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the client. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some clients that reject any attempt to use the older SSL protocol and require that only TLS be used.

lpszCertStore

An optional string value that specifies the name of the certificate store that contains the server certificate. If the certificate is stored in the registry, this parameter must specify a valid local certificate store name. If the certificate is stored in a file, this parameter should specify the full path to the file that contains the certificate. If this parameter is omitted, the personal certificate store for the current process will be used.

lpszCertName

A string value that specifies the name of the certificate. This parameter is required and cannot be NULL. Either the common name or the name assigned to the certificate may be specified. In most cases, this will be the fully qualified domain name of the host that the server is running on.

lpszPassword

An optional string value that specifies a password associated with the server certificate. This parameter is usually only required when the ***lpszCertStore*** parameter specifies a certificate stored in a file. If the server certificate does not have a password associated with it, this parameter or omitted.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

CInternetServer::SetClientData Method

```
BOOL SetClientData(
   SOCKET hClient,
   LPVOID lpvData
);

BOOL SetClientData(
   LPVOID lpvData
);
```

Associate application defined data with the specified client session.

Parameters

hClient

An optional parameter that specifies the handle to the client socket. If this parameter is omitted, the socket handle for the active client session will be used. If this method is called outside of a server event handler, the socket handle must be specified.

lpvData

Pointer to the application defined data associated with the specified client session.

Return Value

If the method succeeds, the return value is non-zero. A return value of zero indicates that application defined data for the client session could not be modified. To get extended error information, call the **GetLastError** method.

Remarks

The **SetClientData** method is used to associate application defined data with a specific client session. This is typically used to associate a pointer to a data structure or a class instance with the client socket. The data can be retrieved using the **GetClientData** method.

You should never specify a pointer to a local variable or data structure that will go out of scope when the calling method exits. If you do this, the pointer will no longer be valid after the method exits and attempting to dereference that pointer at some later time can cause an exception to be thrown and terminate the program. You should always allocate a block of memory for the data using a method such as **HeapAlloc** or **LocalAlloc**. If you specify the address of a static or global data structure, you must use thread synchronization methods when dereferencing and modifying that structure.

Example

```
UINT *pnValue1 = new UINT;
UINT *pnValue2 = NULL;

*pnValue1 = 1234;

if (!pServer->SetClientData(hClient, pnValue1))
{
    // Unable to associate the data with this session
    return;
}

if (!pServer->GetClientData(hClient, (LPVOID *)&pnValue2))
{
    // Unable to retrieve the data associated with this session
```

```
    return;
}

// pnValue2 == pnValue1
printf("The value of the user defined data is %u\n", *pnValue2);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

GetClientData

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::SetClientMoniker Method

```
INT SetClientMoniker(
   SOCKET hSocket,
   LPCTSTR lpszMoniker
);

INT SetClientMoniker(
   LPCTSTR lpszMoniker
);
```

Associate a unique string alias with the specified client session.

Parameters

hSocket

An optional parameter that specifies the handle to the client socket. If this parameter is omitted, the socket handle for the active client session will be used. If this method is called outside of a server event handler, the socket handle must be specified.

lpszMoniker

Pointer to a string which specifies the moniker for the specified client socket. If this parameter is NULL or specifies an empty string, a moniker will no longer be associated with the client session.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is INET_ERROR. To get extended error information, call the **GetLastError** method.

Remarks

A client moniker is a string which can be used to uniquely identify a specific client session aside from its socket handle. The **GetClientMoniker** method will return the moniker that was previously assigned to the client, if any. To obtain the socket handle associated with a given moniker, use the **FindClient** method.

Monikers are not case-sensitive, and they must be unique so that no client socket for a particular server can have the same moniker. The maximum length for a moniker is 127 characters.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

FindClient, GetClientHandle, GetClientId, GetClientMoniker

CInternetServer::SetLastError Method

```
VOID SetLastError(
   DWORD dwErrorCode
);
```

The **SetLastError** method sets the last error code for the current thread. This method is typically used to clear the last error by specifying a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_SOCKET or INET_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

Applications can retrieve the value saved by this method by using the **GetLastError** method. The use of **GetLastError** is optional; an application can call the method to determine the specific reason for a method failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

GetErrorString, GetLastError, ShowError

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::SetOptions Method

```
BOOL SetOptions(
   DWORD dwOptions
);
```

Set one or more server options.

Parameters

dwOptions

An unsigned integer that specifies one or more option bit flags.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero.

Remarks

The **SetOptions** method sets the server options for the class instance. For a list of the available options, see Server Option Constants. This method should only be called prior to invoking the **Start** method, it does not have any effect on an active server. The **GetOptions** method returns the options that are currently specified for the server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

GetOptions, Data Members

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::SetPriority Method

```
INT SetPriority(
   INT nPriority
);
```

Set the priority assigned to the specified server.

Parameters

nPriority

An integer that specifies the server priority. It may be one of the following values:

Value	Description
INET_PRIORITY_BACKGROUND	This priority significantly reduces the memory, processor and network resource utilization for the server. It is typically used with lightweight services running in the background that are designed for few client connections. The server thread will be assigned a lower scheduling priority and will be frequently forced to yield execution to other threads.
INET_PRIORITY_LOW	This priority lowers the overall resource utilization for the server and meters the processor utilization for the server thread. The server thread will be assigned a lower scheduling priority and will occasionally be forced to yield execution to other threads.
INET_PRIORITY_NORMAL	The default priority which balances resource and processor utilization. This is the priority that is initially assigned to the server when it is started, and it is recommended that most applications use this priority.
INET_PRIORITY_HIGH	This priority increases the overall resource utilization for the server and the thread will be given higher scheduling priority. It is not recommended that this priority be used on a system with a single processor.
INET_PRIORITY_CRITICAL	This priority can significantly increase processor, memory and network utilization. The server thread will be given higher scheduling priority and will be more responsive to client connection requests. It is not recommended that this priority be used on a system with a single processor.

Return Value

If the method succeeds, the return value is the previous priority assigned to the server. If the method fails, the return value is INET_ERROR.

Remarks

The **SetPriority** method changes the current priority assigned to the specified server. Client connections that are accepted after this method is called will inherit the new priority as their default priority. Previously existing client connections will not be affected by this function.

Higher priority values increase the thread priority and processor utilization for each client session. You should only change the server priority if you understand the impact it will have on the system and have thoroughly tested your application. Configuring the server to run with a higher priority can have a negative effect on the performance of other programs running on the system.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

GetPriority

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::SetStackSize Method

```
BOOL SetStackSize(
   DWORD dwStackSize
);
```

Change the initial size of the stack allocated for threads created by the server.

Parameters

dwStackSize

The amount of memory that will be committed to the stack for each thread created by the server. If this value is zero, a default stack size will be used.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **SetStackSize** method changes the initial amount of memory that is committed to the stack for each thread created by the server. By default, the stack size for each thread is set to 256K for 32-bit processes and 512K for 64-bit processes. Increasing or decreasing the stack size will only affect new threads that are created by the server, it will not affect those threads that have already been created to manage active client sessions. It is recommended that most applications use the default stack size.

You should not change this value unless you understand the impact that it will have on your system and have thoroughly tested your application. Increasing the initial commit size of the stack will remove pages from the total system commit limit, and every page of memory that is reserved for stack cannot be used for any other purpose.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

GetStackSize, Start

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::SetTimeout Method

```
INT SetTimeout(
   UINT nTimeout
);
```

Set the timeout interval used when waiting for a blocking operation to complete.

Parameters

nTimeout

The number of seconds to wait for a blocking operation to complete.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is INET_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **SetTimeout** method sets the amount of time that the server will wait for data to become available to read, and the default timeout for blocking network operations for each client session. If this method is invoked before the server has started, it will change the default timeout period for the entire server. If this method is invoked within a server event handler, it will change the timeout period for the active client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

GetTimeout, IsReadable, IsWritable, OnTimeout

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::ShowError Method

```
INT ShowError(
   LPCTSTR lpszAppTitle,
   UINT uType,
   DWORD dwErrorCode
);
```

Display a message box which describes the specified error.

Parameters

lpszAppTitle

A null-terminated string which specifies the title of the message box that is displayed. If this argument is NULL or omitted, then the default title of "Error" will be displayed.

uType

An unsigned integer which specifies the type of message box that will be displayed. This is the same value that is used by the **MessageBox** method in the Windows API. If a value of zero is specified, then a message box with a single OK button will be displayed. Refer to that method for a complete list of options.

dwErrorCode

Specifies the error code that will be used when displaying the message box. If this argument is zero, then the last error that occurred in the current thread will be displayed.

Return Value

If the method is successful, the return value will be the return value from the **MessageBox** function. If the method fails, it will return a value of zero.

Remarks

The **ShowError** method will display a modal message box with an error message that corresponds to the specified error code. All top-level windows belonging to the current thread will be disabled until the user responds to the message box. An application should only invoke this method from within the main UI thread, never from within a server event handler such as **OnConnect**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetErrorString, GetLastError, SetLastError

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::Start Method

```
BOOL Start(
   LPCTSTR lpszLocalHost,
   UINT nLocalPort,
   UINT nMaxClients,
   DWORD dwOptions
);

BOOL Start(
   LPCTSTR lpszLocalHost,
   UINT nLocalPort,
   DWORD dwOptions
);

BOOL Start(
   UINT nLocalPort,
   DWORD dwOptions
);

BOOL Start(
   UINT nLocalPort
);
```

The **Start** method begins listening for client connections on the specified local address and port number. The server is started in its own thread and manages the client sessions independently of the calling thread. All interaction with the server and its client sessions takes place inside the class event handlers.

Parameters

lpszLocalHost

A null-terminated string which specifies the local hostname or IP address address that the server should be bound to. If this parameter is omitted or specifies a NULL pointer an appropriate address will automatically be used. If a specific address is used, the server will only accept client connections on the network interface that is bound to that address.

nLocalPort

The port number the server should use to listen for client connections. The port number used by the application must be unique and multiple instances of a server cannot use the same port number. It is recommended that a port number greater than 5000 be used for private, application-specific implementations.

nMaxClients

The maximum number of client connections that can be established with the server. A value of zero specifies that there should not be any fixed limit on the number of active client connections. This value can be adjusted after the server has been created by calling the **Throttle** method.

dwOptions

An unsigned integer value that specifies one or more options to be used when creating an instance of the server. For a list of the available options, see Server Option Constants. If this parameter is omitted, the default options for the server instance will be used.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To

get extended error information, call **GetLastError**.

Remarks

In most cases, the *lpszLocalHost* parameter should be omitted or a NULL pointer. On a multihomed system, this will enable the server to accept connections on any appropriately configured network adapter. Specifying a hostname or IP address will limit client connections to that particular address. Note that the hostname or address must be one that is assigned to the local system, otherwise an error will occur.

If an IPv6 address is specified as the local address, the system must have an IPv6 stack installed and configured, otherwise the method will fail.

To listen for connections on any suitable IPv4 interface, specify the special dotted-quad address "0.0.0.0". You can accept connections from clients using either IPv4 or IPv6 on the same socket by specifying the special IPv6 address "::0", however this is only supported on Windows 7 and Windows Server 2008 R2 or later platforms. If no local address is specified, then the server will only listen for connections from clients using IPv4. This behavior is by design for backwards compatibility with systems that do not have an IPv6 TCP/IP stack installed.

The server instance is managed in another thread, and all interaction with the server and active client connections are performed inside the event handlers. To disconnect all active connections, close the listening socket and terminate the server thread, call the **Stop** method.

Example

```
// EchoServer implementation
class CEchoServer : public CInternetServer
{
    void OnRead(SOCKET hSocket)
    {
        // Read data sent by the client to the server
        BYTE ioBuffer[1024];
        INT nBytesRead = Read(hSocket, ioBuffer, sizeof(ioBuffer));

        // Send a copy of the data back to the client
        if (nBytesRead > 0)
            Write(hSocket, ioBuffer, nBytesRead);
    }
};

int _tmain(int argc, _TCHAR* argv[])
{
    CEchoServer myServer;

    // Start the server listening for connections on port 7000
    if (myServer.Start(7000))
    {
        TCHAR szCommand[128], *pszCommand;

        // Process commands entered by the user at the console
        while (TRUE)
        {
            if ((pszCommand = _fgetts(szCommand, 128, stdin)) == NULL)
                break;

            if (_tcsicmp(pszCommand, _T("quit")) == 0)
                break;
        }
```

```
        // Stop the server and terminate all clients
        myServer.Stop();
    }

    return 0;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

CInternetServer::Stop Method

```
BOOL Stop();
```

Stop the server, terminating all active client sessions and releasing the resources that were allocated for the server.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it will return a value of zero.

Remarks

The **Stop** method instructs the server to stop accepting client connections, disconnects all active client connections and terminates the thread that is managing the server session. The handle is no longer valid after the server has been stopped and should no longer be used. Note that it is possible that the actual handle value may be re-used at a later point when a new server is started. An application should always consider the server handle to be opaque and never depend on it being a specific value.

If an application calls this method from within an event handler, the active client session (the client for which the event handler was invoked) may not get a disconnect notification. It is recommended that this method only be called by the same thread that created the server using the **Start** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

CInternetServer::StoreStream Method

```
BOOL StoreStream(
   LPCTSTR lpszFileName,
   DWORD dwLength,
   LPDWORD lpdwCopied
   DWORD dwOffset,
   DWORD dwOptions
);
```

The **StoreStream** method reads the socket data stream and stores the contents in the specified file.

Parameters

lpszFileName

Pointer to a string which specifies the name of the file to create or overwrite.

dwLength

An unsigned integer which specifies the maximum number of bytes to read from the socket and write to the file. If this value is zero, then the method will continue to read data from the socket until the remote host disconnects or an error occurs.

lpdwCopied

A pointer to an unsigned integer value which will contain the number of bytes written to the file when the method returns.

dwOffset

An unsigned integer which specifies the byte offset into the file where the method will start storing data read from the socket. Note that all data after this offset will be truncated. A value of zero specifies that the file should be completely overwritten if it already exists.

dwOptions

An unsigned integer value which specifies one or more options. Programs can use a bitwise operator to combine any of the following values:

Value	Description
INET_STREAM_CONVERT	The data stream is considered to be textual and will be modified so that end-of-line character sequences are converted to follow standard Windows conventions. This will ensure that all lines of text are terminated with a carriage-return and linefeed sequence. Because this option modifies the data stream, it should never be used with binary data. Using this option may result in the amount of data written to the file to be larger than the source data. For example, if the source data only terminates a line of text with a single linefeed, this option will have the effect of inserting a carriage-return character before each linefeed.
INET_STREAM_UNICODE	The data stream should be converted to Unicode. This option should only be used with text data, and will result in the stream data being written as 16-bit wide characters rather than 8-bit bytes. The amount of data returned will be twice the amount read from the

	source data stream. If the *dwOffset* parameter has a value of zero, the Unicode byte order mark (BOM) will be written to the beginning of the file.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **StoreStream** method enables an application to read an arbitrarily large stream of data and store it in a file. This method is essentially a simplified version of the **ReadStream** method, designed specifically to be used with files rather than memory buffers or handles.

Example

```
// Store all data sent by the client in a file
DWORD dwCopied = 0;
BOOL bResult = pServer->StoreStream(lpszFileName, 0, &dwCopied, 0,
INET_STREAM_CONVERT);

// Close the client connection to the server
pServer->Disconnect();

if (bResult && dwCopied > 0)
{
    // Process the data has been written to the file
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

CInternetServer::Suspend Method

```
BOOL Suspend();
```

Suspend the server and reject new client connections.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **Suspend** method instructs the server to suspend accepting new client connections. Any incoming client connections will be rejected with an error message indicating that the server is currently unavailable. To resume accepting client connections, call the **Resume** method. Suspending the server will have no effect on clients that have already established a connection with the server.

It is recommended that you only suspend a server if absolutely necessary, and only for brief periods of time. If you want to limit the number of active client connections or control the connection rate for clients, use the **Throttle** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

Restart, Resume, Start, Stop, Throttle

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::Throttle Method

```
BOOL Throttle(
   UINT nMaxClients,
   UINT nMaxClientsPerAddress,
   DWORD dwConnectionRate
);
```

The **Throttle** method limits the number of active client connections, connections per address and connection rate.

Parameters

nMaxClients

A value which specifies the maximum number of clients that may connect to the server. A value of zero specifies that there is no fixed limit to the number of client connections. A value of -1 specifies that the maximum number of clients should not be changed.

nMaxClientsPerAddress

A value which specifies the maximum number of clients that may connect to the server from the same IP address. A value of zero specifies that there is no fixed limit to the number of client connections per address. By default, there is a limit of four client connections per address. A value of -1 specifies that the maximum number of clients should not be changed.

dwConnectionRate

A value which specifies a restriction on the rate of client connections, limiting the number of connections that will be accepted within that period of time. A value of zero specifies that there is no restriction on the rate of client connections. The higher this value, the fewer the number of connections that will be accepted within a specific period of time. By default, there is no limit on the client connection rate. A value of -1 specifies that the connection rate should not be changed.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **Throttle** method is used to limit the number of connections and the connection rate to minimize the potential impact of a large number of client connections over a short period of time. This can be used to protect the server from a client application that is malfunctioning or a deliberate denial-of-service attack in which the attacker attempts to flood the server with connection attempts.

If the maximum number of client connections or maximum number of connections per address is exceeded, the server will reject subsequent connection attempts until the number of active client sessions drops below the specified threshold. Note that adjusting these values lower than the current connection limits will not affect clients that have already connected to the server. For example, if the **Start** method is called with the maximum number of clients set to 100, and then **Throttle** is called lowering that value to 75, no existing client connections will be affected by the change. However, the server will not accept any new connections until the number of active clients drops below 75.

Increasing the connection rate value will force the server to slow down the rate at which it will accept incoming client connection requests. For example, setting this parameter to a value of 1000 would limit the server to accepting one client connection every second, while a value of 250 would allow the server to accept four client connections per second. Note that significantly increasing the amount of

time the server must wait to accept client connections can exceed the connection backlog queue, resulting in client connections being rejected.

It is recommended that you always specify conservative connection limits for your server application based on expected usage. Allowing an unlimited number of client connections can potentially expose the system to denial-of-service attacks and should never be done for servers that are accessible over the Internet.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

CInternetServer::Unlock Method

```
BOOL Unlock();
```

Unlock the server, allowing other client threads to resume execution.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **Unlock** method releases the lock on the specified server and allows any blocked threads to resume execution. Only one server may be locked at any one time, and only the thread which established the lock can unlock the server.

Every time the **Lock** method is called, an internal lock counter is incremented, and the lock will not be released until the lock count drops to zero. This means that each call to the **Lock** method must be matched by an equal number of calls to the **Unlock** method. Failure to do so will result in the server becoming non-responsive as it remains in a locked state.

The program should always check the return value from this method, and should never assume that the lock has been released. If a potential deadlock situation is detected, this method will fail and return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

CInternetServer::ValidateCertificate Method

```
BOOL ValidateCertificate(
   LPCTSTR lpszCertStore,
   LPCTSTR lpszCertPassword,
   LPCTSTR lpszCertName
);
```

The **ValidateCertificate** method determines if the specified security certificate is installed on the local system.

Parameters

lpszCertStore

A null-terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the personal certificate store will be used as the default. This parameter may also specify the name of a certificate file in PKCS #12 (PFX) format.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

lpszCertPassword

A null-terminated string which specifies the password associated with a certificate file. This parameter is only used if the ***lpszCertStore*** parameter specifies a certificate file, otherwise it is ignored. If the certificate file is not protected with a password, this parameter should be a NULL pointer or empty string.

lpszCertName

A null-terminated string which specifies the name of the certificate to validate. The method will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the method will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the method will return an error indicating that the certificate could not be found.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To

get extended error information, call **InetGetLastError**.

Remarks

If you are checking the validity of a certificate installed in the local certificate store, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, then it will default to the certificate store for the current user.

It is possible to validate a certificate file rather than one stored in the local certificate store. The *lpszCertStore* member should specify the name of a file in Private Information Exchange (PFX) format, also known as PKCS #12.These certificate files typically have an extension of .pfx or .p12. If a password was specified when the certificate file was created, it must be provided in with the *lpszCertPassword* parameter or this method will be unable to access the certificate.

This method can only validate certificate files in PFX format and cannot be used to validate a certificate file in another format, such as PEM (base64 encoded) or DER (binary).

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

CInternetServer::Write Method

```
INT Write(
   SOCKET hSocket,
   LPBYTE lpBuffer,
   INT cbBuffer
);

INT Write(
   LPBYTE lpBuffer,
   INT cbBuffer
);
```

Send the contents of the specified buffer to to the client.

Parameters

hSocket

An optional parameter that specifies the handle to the client socket. If this parameter is omitted, the socket handle for the active client session will be used. If this method is called outside of a server event handler, the socket handle must be specified.

lpBuffer

The pointer to the buffer which contains the data that is to be sent to the client.

cbBuffer

The number of bytes to send from the specified buffer. This value must be greater than zero.

Return Value

If the method succeeds, the return value is the number of bytes actually written. If the method fails, the return value is INET_ERROR. To get extended error information, call the **GetLastError** method.

Remarks

The return value may be less than the number of bytes specified by the ***cbBuffer*** parameter. In this case, the data has been partially written and it is the responsibility of the client application to send the remaining data at some later point.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

IsReadable, IsWritable, Read, ReadLine, WriteLine

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::WriteLine Method

```
BOOL WriteLine(
   SOCKET hSocket,
   LPCTSTR lpszBuffer,
   LPINT lpnLength
);

BOOL WriteLine(
   LPCTSTR lpszBuffer,
   LPINT lpnLength
);
```

Write a line of data to the client, terminated with a carriage-return and linefeed.

Parameters

hSocket

An optional parameter that specifies the handle to the client socket. If this parameter is omitted, the socket handle for the active client session will be used. If this method is called outside of a server event handler, the socket handle must be specified.

lpszBuffer

The pointer to a string buffer which contains the data that will be sent to the remote host. All characters up to, but not including, the terminating null character will be written to the socket. The data will always be terminated with a carriage-return and linefeed control character sequence. If this parameter points to an empty string or NULL pointer, then a only a carriage-return and linefeed are written to the socket.

lpnLength

A pointer to an integer value which will contain the number of characters written to the socket, including the carriage-return and linefeed sequence. If this information is not required, a NULL pointer may be specified.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **WriteLine** method writes a line of text to the remote host and terminates the line with a carriage-return and linefeed control character sequence. Unlike the **Write** method which writes arbitrary bytes of data to the socket, the **WriteLine** method is specifically designed to write a single line of text data from a null-terminated string. This method will force the session thread to block until the complete line of text has been written, the write operation times out or the remote host aborts the connection.

There are some limitations when using **WriteLine**. This method should only be used to send text, never binary data. In particular, it will discard nulls and append linefeed and carriage return control characters to the data stream. The Unicode version of this method will accept a Unicode string, however it does not support writing raw Unicode data to the socket. Unicode strings will be automatically converted to UTF-8 encoding using the **WideCharToMultiByte** function and then written to the socket as a stream of bytes.

The **Write** and **WriteLine** methods can be safely intermixed.

Unlike the **Write** method, it is possible for data to have been written to the socket if the return value is

zero. For example, if a timeout occurs while the method is waiting to send more data to the remote host, it will return zero; however, some data may have already been written prior to the error condition. If this is the case, the ***lpnLength*** argument will specify the number of characters actually written up to that point.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

IsWritable, Read, ReadLine, ReadStream, Write, WriteStream

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::WriteStream Method

```
BOOL WriteStream(
   SOCKET hSocket,
   LPVOID lpvBuffer,
   LPDWORD lpdwLength,
   DWORD dwOptions
);

BOOL WriteStream(
   LPVOID lpvBuffer,
   LPDWORD lpdwLength,
   DWORD dwOptions
);
```

Write a stream of data to the client.

Parameters

hSocket

An optional parameter that specifies the handle to the client socket. If this parameter is omitted, the socket handle for the active client session will be used. If this method is called outside of a server event handler, the socket handle must be specified.

lpvBuffer

Pointer to the buffer that contains or references the data to be written to the socket. The actual argument depends on the value of the ***dwOptions*** parameter which specifies how the data stream will be accessed.

lpdwLength

A pointer to an unsigned integer value which specifies the size of the buffer and contains the number of bytes written when the method returns. This argument should should always point to an initialized value. If the ***lpvBuffer*** argument specifies a memory buffer or global memory handle, then this argument cannot point to an initialized value of zero.

dwOptions

An unsigned integer value which specifies the stream buffer type to be used when writing the data stream to the socket. One of the following stream types may be specified:

Value	Description
INET_STREAM_DEFAULT	The default stream buffer type is determined by the value passed as the ***lpvBuffer*** parameter. If the argument specifies a a global memory handle, then the method will write the data referenced by that handle; otherwise, the method will consider the parameter a pointer to a block of memory which contains data to be written. In most cases, it is recommended that an application explicitly specify the stream buffer type rather than using the default value.
INET_STREAM_MEMORY	The ***lpvBuffer*** argument specifies a pointer to a block of memory which contains the data to be written to the socket. If this stream buffer type is used, the ***lpdwLength*** argument must point to an unsigned

	integer which has been initialized with the size of the buffer.
INET_STREAM_HGLOBAL	The ***lpvBuffer*** argument specifies a global memory handle that references the data to be written to the socket. The handle must have been created by a call to the GlobalAlloc or GlobalReAlloc function. If this stream buffer type is used, the ***lpdwLength*** argument must point to an unsigned integer which has been initialized with the size of the buffer.
INET_STREAM_HANDLE	The ***lpvBuffer*** argument specifies a Windows handle to an open file, console or pipe. This should be the same handle value returned by the CreateFile function in the Windows API. The data read using the ReadFile function with this handle will be written to the socket.
INET_STREAM_SOCKET	The ***lpvBuffer*** argument specifies a socket handle. The data read from the socket specified by this handle will be written to the socket specified by the ***hSocket*** parameter. The socket handle passed to this method must have been created by this library; if it is a socket created by an third-party library or directly by the Windows Sockets API, you should either create another instance of the class and attach the socket using the AttachHandle method or use the INET_STREAM_HANDLE stream buffer type instead.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The **WriteStream** method enables an application to write an arbitrarily large stream of data from memory or a file to the specified socket. Unlike the **Write** method, which may not write all of the data in a single method call, **WriteStream** will only return when all of the data has been written or an error occurs. This method will force the thread to block until the operation completes.

It is possible for some data to have been written even if the method returns a value of zero. Applications should also check the value of the ***lpdwLength*** argument to determine if any data was sent. For example, if a timeout occurs while the method is waiting to write more data, it will return zero; however, some data may have already been written to the socket prior to the error condition.

Example

```
CFile *pFile = new CFile();
DWORD dwLength = 0;

if (!pFile->Open(strFileName, CFile::modeRead | CFile::shareDenyWrite))
    return;

dwLength = pFile->GetLength();
```

```
if (dwLength > 0)
{
    BOOL bResult = pServer->WriteStream(
                      pFile->m_hFile,
                      &dwLength,
                      INET_STREAM_HANDLE);
}

delete pFile;
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

CInternetServer Event Handlers

Method	Description
OnAccept	The client is attempting to establish a connection to the server
OnConnect	The client has established a connection to the server
OnDisconnect	The client has disconnected from the server
OnError	The event handler encountered an error when processing a client event
OnRead	The client has sent data to the server
OnTimeout	The client has not sent data within the specified timeout period
OnWrite	The client is ready to receive data from the server

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::OnAccept Method

```
virtual void OnAccept(
   SOCKET hSocket
);
```

A virtual method that is invoked when a client attempts to connect to the server.

Parameters

hSocket

A handle to the server socket.

Return Value

None.

Remarks

The **OnAccept** event handler is invoked when a client attempts to connect to the server, but prior to the connection being accepted. To implement an event handler, the application should create a class derived from the **CInternetServer** class, and then override this method.

This event only occurs before the server has checked the active client limits. This event is typically used to reject a connection based on some criteria established by the server, such as the IP address of the client attempting to make the connection. To obtain the IP address of the client that is attempting to connect to the server, use the **GetClientAddress** method using the server handle.

If this event handler is not implemented, the server will permit the client connection to complete. To reject the connection attempt, call the **Reject** method using the handle to the server socket. Rejecting the client connection within the **OnAccept** event handler may cause unexpected behavior by the client application because the connection process will not complete normally. Instead of rejecting the client connection within the **OnAccept** handler, it is recommended that most server applications implement an **OnConnect** event handler, perform any required checks and then gracefully disconnect the client using the **Disconnect** method if needed.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

Disconnect, OnConnect, OnDisconnect

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::OnConnect Method

```
virtual void OnConnect(
   SOCKET hSocket,
   UINT nClientId,
   LPCTSTR lpszAddress,
   UINT nPort
);
```

A virtual method that is invoked after the client has connected to the server.

Parameters

hSocket

A handle to the client socket.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszAddress

A string that specifies the IP address of the client. This address may either be in IPv4 or IPv6 format, depending on how the server was configured and the address the client used to establish the connection.

nPort

An integer that specifies the port number that the client socket is bound to.

Return Value

None.

Remarks

The **OnConnect** event handler is invoked after the client has connected to the server. To implement an event handler, the application should create a class derived from the **CInternetServer** class, and then override this method.

This event only occurs after the server has checked the active client limits and the TLS handshake has been performed, if security has been enabled. If the server has been suspended, or the limit on the maximum number of client sessions has been exceeded, the server will reject the connection prior to this event handler being invoked.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

Disconnect, OnAccept, OnDisconnect

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::OnDisconnect Method

```
virtual void OnDisconnect(
   SOCKET hSocket
);
```

A virtual method that is invoked when a client disconnects from the server.

Parameters

hSocket

A handle to the client socket.

Return Value

None.

Remarks

The **OnDisconnect** event handler is invoked when a client disconnects from the server, immediately before the client session is terminated. To implement an event handler, the application should create a class derived from the **CInternetServer** class, and then override this method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

Disconnect, OnConnect

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::OnError Method

```
virtual void OnConnect(
   SOCKET hSocket,
   UINT nEventId,
   DWORD dwError
);
```

A virtual method that is invoked when the server encounters an error while handling a client request.

Parameters

hSocket

An unsigned integer which uniquely identifies the client session.

nEventId

An unsigned integer which identifies the client event that was being processed when the error occurred. For a list of event identifiers, see Server Event Constants.

dwError

An unsigned integer value that specifies the error code.

Return Value

None.

Remarks

The **OnError** event handler is invoked whenever an error occurs while an event is being processed by the server. To implement an event handler, the application should create a class derived from the **CInternetServer** class, and then override this method.

It is important to note that this event is not raised for every error that occurs. The event only occurs when another event is being processed and an unhandled error occurs that must be reported back to the server application. The following are some common situations in which this event handler may be invoked:

- A network error occurs when the client connection is being accepted by the server. This could be the result of an aborted connection or some other lower-level failure reported by the networking subsystem on the server.
- The server is configured to use implicit TLS but cannot obtain the security credentials required to create the security context for the session. Usually this indicates that the server certificate cannot be found, or the certificate does not have a private key associated with it. It could also indicate a general problem with the cryptographic subsystem where the client and server could not successfully negotiate a cipher suite.
- Network errors that may occur when attempting to buffer data sent by the client. This usually indicates that the connection to the client has been aborted, either because the client is not acknowledging the data that has been exchanged with the server, or the client has terminated abnormally. This event will not occur if the client terminates the connection normally.

In most situations where this event handler is invoked, the error is not recoverable and the only action that can be taken is to terminate the client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

OnConnect, OnDisconnect, OnTimeout

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::OnRead Method

```
virtual void OnRead(
   SOCKET hSocket
);
```

A virtual method that is invoked when a client sends data to the server.

Parameters

hSocket

A handle to the client socket.

Return Value

None.

Remarks

The **OnRead** event handler is invoked when a client sends data to the server. To implement an event handler, the application should create a class derived from the **CInternetServer** class, and then override this method. All server applications must implement an **OnRead** event handler to process the data sent by the client.

This event occurs whenever there is data available to be read from the client. The server application reads the data using the **Read** or **ReadLine** method, and can then send data back to the client using the **Write** or **WriteLine** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

Read, ReadLine, Write, WriteLine, OnWrite

CInternetServer::OnTimeout Method

```
virtual void OnTimeout(
   SOCKET hSocket
);
```

A virtual method that is invoked when the client has not sent any data to the server within the timeout period.

Parameters

hSocket

A handle to the client socket.

Return Value

None.

Remarks

The **OnTimeout** event handler is invoked when a client has not sent any data to the server within the timeout period specified when the server was started. To implement an event handler, the application should create a class derived from the **CInternetServer** class, and then override this method.

This event handler is typically used to monitor the amount of time that a client is idle. The default timeout period for the server is 20 seconds, which would cause this event handler to be invoked whenever a client has not sent any data to the server in the last 20 seconds. The server may take no action, or it may disconnect the client after it has been idle for an extended period of time. To get the total amount of time that the client has been idle, call the **GetClientIdleTime** method. Note that while the server timeout period is specified in seconds, the **GetClientIdleTime** method returns the client idle time in milliseconds.

The default implementation for this event handler is to take no action. It is recommended that most server applications disconnect clients that are inactive. For typical client-server implementations that use transitory connections (where the client sends a single request to the server, the server responds and the connection is terminated) the amount of time that a client should be permitted to remain idle should be relatively low, usually 60 seconds or less. For persistent connections where there are multiple requests issued by the client over the lifetime of the session, a longer idle timeout period may be preferable.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetClientIdleTime

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CInternetServer::OnWrite Method

```
virtual void OnWrite(
   SOCKET hSocket
);
```

A virtual method that is invoked when the client is ready to receive data.

Parameters

hSocket

A handle to the client socket.

Return Value

None.

Remarks

The **OnWrite** event handler is invoked when a client is ready to receive data. To implement an event handler, the application should create a class derived from the **CInternetServer** class, and then override this method. All server applications must implement an **OnRead** event handler to process the data sent by the client.

This event occurs immediately after the **OnConnect** event and if security is enabled, after the TLS handshake has completed. It is used to notify the server application that the client is ready to receive data, and may be used to send an initial message to the client, typically identifying the server that it has connected to. In most cases, the **OnWrite** event handler will only be invoked once over the lifetime of the client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

Internet Server Data Structures

- INETSTREAMINFO
- INTERNET_ADDRESS

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

INETSTREAMINFO

This structure contains information about the data stream being currently read or written.

```
typedef struct _INETSTREAMINFO
{
    DWORD   dwStreamThread;
    DWORD   dwStreamSize;
    DWORD   dwStreamCopied;
    DWORD   dwStreamMode;
    DWORD   dwStreamError;
    DWORD   dwBytesPerSecond;
    DWORD   dwTimeElapsed;
    DWORD   dwTimeEstimated;
} INETSTREAMINFO, *LPINETSTREAMINFO;
```

Members

dwStreamThread

Specifies the numeric ID for the thread that created the socket.

dwStreamSize

The maximum number of bytes that will be read or written. This is the same value as the buffer length specified by the caller, and may be zero which indicates that no maximum size was specified. Note that if this value is zero, the application will be unable to calculate a completion percentage or estimate the amount of time for the operation to complete.

dwStreamCopied

The total number of bytes that have been copied to or from the stream buffer.

dwStreamMode

A numeric value which specifies the stream operation that is current being performed. It may be one of the following values:

Value	Description
INET_STREAM_READ	Data is being read from the socket and stored in the specified stream buffer.
INET_STREAM_WRITE	Data is being written from the specified stream buffer to the socket.

dwStreamError

The last error that occurred when reading or writing the data stream. If no error has occurred, this value will be zero.

dwBytesPerSecond

The average number of bytes that have been copied per second.

dwTimeElapsed

The number of seconds that have elapsed since the file transfer started.

dwTimeEstimated

The estimated number of seconds until the operation is completed. This is based on the average number of bytes transferred per second and requires that a maximum stream buffer size be specified by the caller.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h

INTERNET_ADDRESS

This structure represents a numeric IPv4 or IPv6 address in network byte order.

```
typedef struct _INTERNET_ADDRESS
{
     INT    ipFamily;
     BYTE   ipNumber[16];
}  INTERNET_ADDRESS, *LPINTERNET_ADDRESS;
```

Members

ipFamily

An integer which identifies the type of IP address. It will be one of the following values:

Value	Description
INET_ADDRESS_UNKNOWN	The address has not been specified or the bytes in the ***ipNumber*** array does not represent a valid address. Functions which populate this structure will use this value to indicate that the address cannot be determined.
INET_ADDRESS_IPV4	Specifies that the address is in IPv4 format. The first four bytes of the ***ipNumber*** array are significant and contains the IP address. The remaining bytes are not significant and an application should not depend on them having any particular value, including zero.
INET_ADDRESS_IPV6	Specifies that the address is in IPv6 format. All bytes in the ***ipNumber*** array are significant. Note that it is possible for an IPv6 address to actually represent an IPv4 address. This is indicated by the first 10 bytes of the address being zero.

ipNumber

A byte array which contains the numeric form of the IP address. This array is large enough to store both IPv4 (32 bit) and IPv6 (128 bit) addresses. The values are stored in network byte order.

Remarks

The **INTERNET_ADDRESS** structure is used by some functions to represent an Internet address in a binary format that is compatible with both IPv4 and IPv6 addresses. Applications that use this structure should consider it to be opaque, and should not modify the contents of the structure directly.

For compatibility with legacy applications that expect an IP address to be 32 bits and stored in an unsigned integer, you can copy the first four bytes of the ***ipNumber*** array using the **CopyMemory** function or equivalent. Note that if this is done, your application should always check the ***ipFamily*** member first to make sure that it is actually an IPv4 address.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

CLlmClient Class Library

The **CLlmClient** class provides a unified, high-level interface for integrating large language model capabilities into applications. It simplifies working with different providers by handling connections, messaging, and conversation state internally, while still giving developers control over configuration, performance, and behavior. The class is designed to support both simple use cases and more advanced scenarios involving model selection, token management, and session control.

- Data Structures
- Providers
- Error Codes

Library Information

Class Name	CLlmClient
File Name	CSLLMV12.DLL
Version	12.0.3024.1286
LibID	E77A6A0A-3B86-49D9-9A3D-A0B425BDA66D
Import Library	CSLLMV12.LIB
Dependencies	None

Overview

The **CLlmClient** class is built around a session-based architecture that encapsulates all aspects of interacting with a language model, including connection details, configuration settings, and conversation history. This design allows developers to treat each interaction as part of a managed context, making it easier to maintain state across multiple requests without needing to manually track prior messages or model parameters. Sessions can be configured with defaults or customized with options such as system prompts, token limits, and behavioral settings, depending on the needs of the application.

A central goal of the class is to abstract the differences between providers and models, presenting a unified interface that works consistently regardless of the underlying service. Developers can discover available providers and models, query their capabilities, and select appropriate configurations at runtime. This flexibility makes it possible to switch between services or adapt to new models with minimal code changes, while still exposing enough detail to fine-tune behavior when needed.

The class also provides robust support for managing conversation data. It maintains a structured history of messages and responses, enabling applications to iterate through prior interactions, search for specific content, or limit the amount of retained context to control memory usage and token consumption. This is particularly important when working with models that have strict context limits, as it allows developers to balance response quality with performance and cost considerations.

In addition to core messaging functionality, the class includes a range of utility features that help developers monitor and optimize their applications. These include estimating and tracking token

usage, managing cache lifetimes for model metadata, handling errors in a consistent way, and optionally logging network activity for debugging purposes. Together, these capabilities provide insight into how the application is interacting with the model and help identify potential performance or configuration issues.

Overall, the **CLlmClient** class is designed to provide a practical balance between simplicity and control. It enables developers to quickly add AI-powered features to their applications while retaining the flexibility to customize behavior, manage resources, and integrate with different providers as requirements evolve.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). You should install all updates for your development tools and have the current Windows SDK installed. The minimum supported version of Visual Studio is Visual Studio 2010 with Service Pack 1 (SP1) installed. The SocketTools header files are designed to be compatible with all modern C/C++ compilers and we also provide function definitions for several additional languages such as Object Pascal and Visual Basic.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are deploying applications to Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. If you are deploying applications to Windows 8, you must have the 8.1 update installed. If you are targeting the Windows on ARM platform, the minimum required version is Windows 10 build 1709.

SocketTools includes support for both 64-bit and 32-bit Windows platforms. All current versions of Windows are 64-bit, and we include 32-bit x86 libraries to maintain compatibility with legacy development tools. SocketTools also provides native ARM64 libraries for systems running Windows on ARM. Note that 32-bit applications on ARM use x86 emulation, and Microsoft no longer supports native 32-bit ARM (ARM32) applications. Embarcadero's C++Builder and Delphi compilers (as of version 12.3) do not support building native ARM64 applications for Windows. For developing applications targeting the Windows on ARM platform, we recommend using Visual Studio 2019 or later.

The import libraries included with SocketTools are provided in several different formats. The most commonly used format is COFF, which is available for x64, x86 and native ARM64 platforms. For compatibility with older Borland (Embarcadero) compilers, we also provide OMF libraries for x86 platforms and ELF libraries for x64 platforms. If you are using Visual Studio, you will want to use the standard COFF import libraries. Note that some languages may not require import libraries and will link to the exported functions in the DLL based on the method declaration itself.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

CLlmClient Methods

Class	Description
CLlmClient	Constructor which initializes the current instance of the class.
~CLlmClient	Destructor which releases resources allocated by the class.
Method	Description
AskModel	Sends a prompt to the specified service provider and model.
AttachHandle	Attaches the specified client handle to this instance of the class.
AttachThread	Attaches the specified client handle to another thread.
Cancel	Cancels the current blocking request.
ClearHeaders	Clears the custom HTTP request headers for the client session.
ClearHistory	Clears the current conversation history for the client.
Connect	Establishes a connection using the specified provider, URL, model, API key, and options.
ConnectEx	Establishes a connection using an existing session structure.
ConvertTimestamp	Converts a message or response timestamp value into a SYSTEMTIME structure.
CreateSession	Creates an internal session object using the specified provider settings.
DeleteSession	Deletes an internal session object and releases its resources.
DetachHandle	Detaches the handle for the current instance of this class.
DisableTrace	Disables logging of network function calls.
Disconnect	Disconnects from the provider and releases the session handle.
EnableTrace	Enables logging of network function calls to a file.
EnumModels	Enumerates the models available for the connected provider.
EnumProviders	Enumerates the supported LLM providers.
EstimateTokenCount	Estimates the number of tokens in a text string for a specific provider.
ExportHistory	Exports the current conversation history to a JSON-formatted file.
FindMessage	Searches the conversation history for a message matching the specified text or flags.
FormatTimestamp	Formats a message timestamp as a ISO 8601 date and time string.
GetCacheTime	Returns the current model or metadata cache lifetime for the client.
GetDefaultModelFlags	Returns the default capability flags for the specified model.
GetDefaultModelName	Returns the default model name for the specified provider.
GetDefaultUrl	Returns the default endpoint URL for the specified provider.
GetErrorString	Returns a text description for the specified error code.
GetFirstMessage	Retrieves the first message in the conversation history.
GetHandle	Returns the client handle used by this instance of the class.
GetHeader	Returns the value of an HTTP header from the server response.
GetHistorySize	Returns the maximum number of messages which can be stored in the conversation history.
GetIdleTime	Returns the current idle timeout period for the client.
GetLastError	Returns the last error code for the current thread.

GetMemoryUsage	Returns the amount of memory currently used for the client session.
GetMessage	Retrieves a specific message prompt and response using the history index.
GetMessageById	Retrieves a specific message prompt and response pair by message ID.
GetMessageCount	Returns the current number of messages in the conversation history.
GetModelContextSize	Returns the context window size for the specified model.
GetModelFlags	Returns the current model behavior flags for the client.
GetModelInfo	Returns detailed information about a specific model.
GetModelName	Returns the name of the current model used with a client session.
GetNextMessage	Retrieves the next message in the conversation history.
GetOptions	Returns the current client option flags.
GetProviderUrl	Returns the provider base URL used for client requests.
GetProviderFlags	Returns the capability flags associated with a provider.
GetProviderId	Returns the current provider ID or one based on a provider name, endpoint URL or model name.
GetProviderInfo	Retrieves detailed information about a provider.
GetProviderName	Returns the display name of a provider.
GetProviderUrl	Returns the provider endpoint URL for the current session.
GetSession	Returns a pointer to the current LLM_SESSION structure.
GetStatusCode	Returns the most recent HTTP status code for the client request.
GetSystemPrompt	Returns the current system prompt for the client session.
GetTimeout	Returns the number of seconds until a request times out.
GetTokenUsage	Returns token usage statistics for the client session.
GetUserAgent	Returns the current user-agent string used by the client.
ImportHistory	Imports a conversation history from the specified JSON-formatted file.
IsBlocking	Returns whether the client is currently processing a blocking operation.
IsConnected	Returns whether the client session is valid and connected to a server.
IsInitialized	Determines if the class has been successfully initialized.
NormalizeText	Normalizes message text into a consistent format.
ResetSession	Resets the current client session to its initial state.
SendMessage	Sends a prompt to the model and returns the response as a string.
SendMessageEx	Sends a structured message to the model and returns a structured response.
SetCacheTime	Sets the cache lifetime used by the client for model or provider data.
SetHeader	Sets the value of a custom HTTP header issued with subsequent requests.
SetHistorySize	Sets the maximum number of messages retained in the conversation history.
SetIdleTime	Sets the idle timeout period for the client session.
SetLastError	Sets the last error code for the current thread.
SetModelFlags	Sets model behavior flags for the client session.
SetModelName	Changes the current model for a client session.
SetOptions	Sets the current client option flags.
SetSystemPrompt	Sets the system prompt for the client session.

SetTimeout	Sets the number of seconds until a blocking operation times out.
SetUserAgent	Sets the user-agent string used by the client.
ShowError	Displays a message box with a description of the specified error.
TrimHistory	Removes older messages from the conversation history, optionally constrained by token usage.
ValidateModel	Validates that a model name is recognized or supported by the current provider.
ValidateText	Performs basic validation on message text before it is submitted to a model.

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CLlmClient::~CLlmClient

```
~CLlmClient();
```

The **CLlmClient** destructor releases resources allocated by the current instance of the **CLlmClient** object. It also uninitializes the library if there are no other concurrent uses of the class.

Remarks

When a **CLlmClient** object goes out of scope, the destructor is automatically called to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all handles that were created for the client session are destroyed.

The destructor is not called explicitly by the application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

See Also

CLlmClient

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CLlmClient::AttachHandle Method

```
VOID AttachHandle(
   HCLIENT hClient
);
```

The **AttachHandle** method attaches the specified client handle to the current instance of the class.

Parameters

hClient

The handle to the client session that will be attached to the current instance of the class object.

Return Value

None.

Remarks

This method is used to attach a client handle created outside of the class using the SocketTools API. Once the client handle is attached to the class, the other class methods may be used with that client session.

If a client handle has already been created for the class, that handle will be released when the new handle is attached to the class object. If you want to prevent the previous client session from being terminated, you must call the **DetachHandle** method. Failure to release the detached handle may result in a resource leak in your application.

Note that the ***hClient*** parameter is presumed to be a valid client handle and no checks are performed to ensure that the handle is valid. Specifying an invalid client handle will cause subsequent method calls to fail.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

See Also

AttachThread, DetachHandle, GetHandle

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CLlmClient::AttachThread Method

```
DWORD AttachThread(
   DWORD dwThreadId
);
```

The **AttachThread** method attaches the specified client handle to another thread.

Parameters

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the method succeeds, the return value is the thread ID of the previous owner. If the method fails, the return value is LLM_ERROR. To get extended error information, call **GetLastError**.

Remarks

When a client handle is created, it is associated with the thread that created it. If another thread attempts to use the handle, the method will fail because that thread does not own the handle. This prevents other threads from interfering with an operation being performed by the owner thread. The **AttachThread** method changes the thread that owns the client handle. This is useful when one thread creates the client session and then passes it to a worker thread for processing. The method returns the thread ID of the previous owner, which can be saved and used later to restore ownership of the handle.

This method should normally be called by the new owner thread immediately after it has been created. If the worker thread does not release the handle itself, ownership should be restored to the original thread before the worker thread terminates. Do not use **AttachThread** to forcibly take ownership of a handle from another thread while a blocking operation is in progress. The handle should only be transferred when no other thread is actively using it.

The ***dwThreadId*** parameter is assumed to be a valid thread ID. This method does not verify that the specified thread exists. Specifying an invalid thread ID will orphan the handle until the destructor is called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

See Also

Connect, Disconnect

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CLlmClient::Cancel Method

```
BOOL Cancel();
```

The **Cancel** method cancels the current blocking request.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **Cancel** method cancels the current blocking request by closing the active HTTP connection associated with the client session. This causes the blocking operation to fail and return control to the calling thread. The last error code for the blocking function will be set to indicate the operation was canceled.

This method cancels the request locally. It does not guarantee that the provider will stop processing a request that has already been received. The provider may still complete the request and may charge for any processing or tokens used before the connection was closed.

Canceling a request does not delete the client session or clear the conversation history. The client handle remains valid, and a new HTTP connection will be established automatically if it is needed for a subsequent request.

If no blocking request is currently in progress, this method succeeds and has no effect.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

See Also

IsBlocking, SendMessage, SendMessageEx

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CLlmClient::ClearHeaders Method

```
BOOL ClearHeaders();
```

The **ClearHeaders** method removes all custom HTTP request headers for the client session.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **ClearHeaders** method removes all custom request header values set using the **SetHeader** method. This is useful when you want to ensure that custom headers used for a previous call to **SendMessage** are not included with subsequent requests made during the same session.

This method does not clear authentication credentials, organization identifiers, project identifiers, or any required headers automatically generated by the control.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

See Also

GetHeader, ResetSession, SendMessage, SetHeader

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CLlmClient::ClearHistory Method

```
BOOL ClearHistory();
```

The **ClearHistory** method clears the conversation history for the current client session.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **ClearHistory** method removes all messages and responses stored in the conversation history for the specified client session. This can be used to begin a new conversation while preserving the current connection, provider settings, model selection, timeout, system prompt and other session options.

This method only clears the local history maintained by the client. It does not reset provider-specific settings, delete cached model information or close the active HTTP connection. It also does not change the current system prompt.

After the history has been cleared, subsequent calls to **SendMessage** or **SendMessageEx** will not include any previous messages from the conversation history.

Clearing the conversation history invalidates any string pointers previously returned in LLM_RESPONSE structures or by message history methods. Applications must not use those pointers after this method returns. If the application needs to keep any message or response text, it should make its own copy before clearing the history.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

See Also

GetHistorySize, SetHistorySize, GetFirstMessage, GetNextMessage, ResetSession, TrimHistory

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CLlmClient::CLlmClient

```
CLlmClient();
```

The **CLlmClient** constructor initializes the class library and validates the runtime license key.

Remarks

If the constructor fails to validate the runtime license, subsequent methods in this class will fail. If the product is installed with an evaluation license, then the application will only function on the development system and cannot be redistributed.

The constructor calls the **LlmInitialize** function to initialize the library, which dynamically loads other system libraries and allocates thread local storage. If you are using this class within another DLL, it is important that you do not create or destroy an instance of the class from within the **DllMain** function because it can result in deadlocks or access violation errors. You should not declare static or global instances of this class within another DLL if it is linked with the C runtime library (CRT) because it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

See Also

~CLlmClient, IsInitialized

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CLlmClient::Connect Method

```
BOOL Connect(
   DWORD dwProviderId,
   DWORD dwOptions,
   INT nTimeout,
   LPCTSTR lpszBaseUrl,
   LPCTSTR lpszModelName,
   LPCTSTR lpszApiKey
);
```

The **Connect** method establishes a connection to the specified large language model service provider and creates a client session.

Parameters

dwProviderId

Specifies the service provider. This parameter must be one of the **LLM_PROVIDER** constants. See the remarks below for more information about service providers.

dwOptions

Specifies one or more option flags that control how the connection is established. This parameter can be zero or a combination of the following values:

Value	Description
LLM_OPTION_NONE	A standard connection to the server is established using the default behavior for the selected provider. No additional options are enabled, and the connection will use the provider's default protocol, caching behavior and request headers.
LLM_OPTION_NOCACHE	Disables provider and model metadata caching for the client session. When this option is specified, the library will not reuse cached metadata, and provider or model information will be retrieved from the server each time it is required. This may be useful when testing or when current data is required.
LLM_OPTION_KEEPALIVE	Enables persistent HTTP connections using the keep-alive mechanism. When enabled, the underlying HTTP connection may be reused for multiple requests, reducing connection overhead and improving performance. If this option is not specified, the connection may be closed after each request.
LLM_OPTION_PROXY	Specifies that the connection should be made using the current Windows proxy server configuration. If the user does not have a proxy server configuration, this option is ignored. This option is typically used in environments where direct internet access is restricted.
LLM_OPTION_NOUSERAGENT	Prevents the library from sending a User-Agent header with requests to the provider. By default, a User-Agent string is included to identify the client. This option may be

	used when a provider does not require a User-Agent header.
LLM_OPTION_SECURE	Forces the use of a secure HTTPS connection when communicating with the provider. If the specified base URL or provider default would normally use an insecure protocol, it will be upgraded to a secure connection. Connections to providers such as OpenAI, Google and Anthropic will always be secure.
LLM_OPTION_DEFAULT	Specifies the default option set, which is equivalent to `LLM_OPTION_NONE`. No additional flags are enabled and the connection uses standard behavior.

nTimeout

The timeout period for connection and request operations, in seconds. A value of zero indicates that the default timeout should be used.

lpszBaseUrl

A pointer to a null-terminated string that specifies the base URL for the provider endpoint. This parameter may be NULL to use the default endpoint for the selected provider. Some providers, such as Microsoft Foundry or local services, require a specific base URL.

lpszModelName

A pointer to a null-terminated string that specifies the model name to use for the session. This parameter may be NULL to use the provider default model, if one is defined. Providers without a default model require an explicit model name.

lpszApiKey

A pointer to a null-terminated string that specifies the API key used to authenticate with the provider. The API key may be provided using a literal string, an environment variable, or a value stored in the Windows Credential Manager. Using an environment variable or secure credential storage is recommended for production applications to avoid exposing sensitive information in source code or application binaries.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **Connect** method creates a client session that is used for all subsequent operations with the selected provider. The returned handle maintains the connection settings, authentication information, selected model, and conversation history for the session.

The *dwProviderId* parameter specifies the numeric identifier assigned to a supported provider. Provider identifiers are predefined constants built into the library and are assigned fixed values beginning at 1 and increasing sequentially for each provider. These identifiers are stable and are intended to uniquely identify a provider regardless of its display name. Applications should use the predefined constants (such as `LLM_PROVIDER_OPENAI` or `LLM_PROVIDER_MICROSOFT`) rather than hard-coding numeric values directly in source code.

Refer to the providers page for a list of supported service providers and their default models.

If the *lpszBaseUrl* parmeter is NULL or a zero-length string, the library will use a provider-specific default endpoint. Some providers, such as Microsoft Foundry services or locally hosted models,

require an explicit endpoint and will fail if one is not provided.

If the *lpszModelName* parameter is NULL or a zero-length string, the library will attempt to use a default model for the selected provider. Not all providers define a default model, and in those cases an explicit model name must be provided when establishing the connection. This typically includes models accessed using the Microsoft Foundry or locally hosted inference providers.

If the service provider requires authentication, the API key can be provided in several formats, allowing applications to provide credentials in a way that balances convenience and security:

- **Literal string**
  The API key is provided directly as a string. This is the simplest approach and is convenient for testing or small internal tools, but it is not recommended for production applications. A literal key may be exposed in source code, configuration files, diagnostic logs or the compiled application binary.
- **Environment variable**
  The name of an environment variable enclosed in percent symbols, for example `"%OPENAI_API_KEY%"`. The value of the environment variable is used as the API key. This avoids embedding the key directly in the application and is useful for development, scripts and deployment environments. However, environment variables may still be visible to the current user, inherited by child processes or exposed through system configuration, so they should still be protected appropriately.
- **Windows credential**
  A credential name enclosed in braces, for example `"{MyAppName/OpenAI}"`. The API key is retrieved from the Windows Credential Manager using the specified name. This is the recommended approach for most Windows applications because the secret is stored outside the application and managed by the operating system. The credential can be created manually using Credential Manager, or programmatically by the application using the Windows Credential Management API. Applications should choose a unique credential name and document it clearly if users or administrators are expected to configure the value themselves.

For production applications, it is recommended that you avoid using literal API key strings and instead use an environment variable or a value stored in the Windows Credential Manager. If you must provide the API key as a literal string, you should take additional steps to protect it, such as storing the key in an encrypted form and limiting access to authorized users or processes. Avoid embedding API keys directly in application source code, configuration files, installers or other content that could be exposed through version control systems, logs or public repositories.

This method will block the calling thread until the connection has been established or the timeout period has elapsed. The connection established by this method represents a logical session. Depending on the provider and options specified, the underlying HTTP connection may be reused across requests or recreated as needed. Options such as `LLM_OPTION_KEEPALIVE` can be used to control connection behavior.

If the class instance is connected to another provider, this method will explicitly close that connection by calling the **Disconnect** method prior to establishing the new connection. If the connection fails, the **GetHandle** method will return INVALID_HANDLE.

The client handle returned by this method is owned by the thread that created it. To transfer ownership to another thread, use the **AttachThread** method.

Example

```
#include "cstools12.h"
#include <stdio.h>

int _tmain(void)
{
    CLlmClient llmClient;

    // Establish a connection to OpenAI using the default endpoint
    // and a lightweight model
    BOOL bConnected = llmClient.Connect(
        LLM_PROVIDER_OPENAI,
        LLM_OPTION_DEFAULT,
        LLM_TIMEOUT,
        NULL,                   // Default endpoint
        _T("gpt-5.4-nano"),     // Model name
        _T("%OPENAI_API_KEY%") // Environment variable
    );

    if (!bConnected)
    {
        DWORD dwError = llmClient.GetLastError();
        _tprintf(_T("Unable to connect, error %lu\n"), dwError);
        return 1;
    }

    TCHAR szResponse[4096] = {0};
    DWORD dwResponseLength = _countof(szResponse); // number of TCHARs
    DWORD dwMessageId = 0;

    // Send a simple message to the model
    if (llmClient.SendMessage(
            _T("What is the capital city of Denmark?"),
            szResponse,
            &dwResponseLength,
            &dwMessageId))
    {
        _tprintf(_T("The response was %lu characters:\n"), dwResponseLength);
        _putts(szResponse);
    }
    else
    {
        DWORD dwError = llmClient.GetLastError();
        _tprintf(_T("Request failed, error %lu\n"), dwError);
    }

     // Close the connection explicitly
    llmClient.Disconnect();
    return 0;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

CLlmClient::ConnectEx Method

```
BOOL ConnectEx(
   DWORD dwProviderId,
   DWORD dwOptions,
   LPLLM_SESSION lpSession
);

BOOL ConnectEx();
```

The **ConnectEx** method establishes a connection to the specified large language model service provider using an extended session configuration.

Parameters

dwProviderId

Specifies the service provider. This parameter must be one of the **LLM_PROVIDER** constants. See the remarks below for more information about service providers.

dwOptions

Specifies one or more option flags that control how the connection is established. This parameter can be zero or a combination of **LLM_OPTION** values. These options control behavior such as connection security, proxy usage, and HTTP connection handling.

Value	Description
LLM_OPTION_NONE	A standard connection to the server is established using the default behavior for the selected provider. No additional options are enabled, and the connection will use the provider's default protocol, caching behavior and request headers.
LLM_OPTION_NOCACHE	Disables provider and model metadata caching for the client session. When this option is specified, the library will not reuse cached metadata, and provider or model information will be retrieved from the server each time it is required. This may be useful when testing or when current data is required.
LLM_OPTION_KEEPALIVE	Enables persistent HTTP connections using the keep-alive mechanism. When enabled, the underlying HTTP connection may be reused for multiple requests, reducing connection overhead and improving performance. If this option is not specified, the connection may be closed after each request.
LLM_OPTION_PROXY	Specifies that the connection should be made using the current Windows proxy server configuration. If the user does not have a proxy server configuration, this option is ignored. This option is typically used in environments where direct internet access is restricted.
LLM_OPTION_NOUSERAGENT	Prevents the library from sending a User-Agent header with requests to the provider. By default, a User-Agent string is included to identify the client. This option may be

	used when a provider does not require a User-Agent header.
LLM_OPTION_SECURE	Forces the use of a secure HTTPS connection when communicating with the provider. If the specified base URL or provider default would normally use an insecure protocol, it will be upgraded to a secure connection. Connections to providers such as OpenAI, Google and Anthropic will always be secure.
LLM_OPTION_DEFAULT	Specifies the default option set, which is equivalent to `LLM_OPTION_NONE`. No additional flags are enabled and the connection uses standard behavior.

lpSession

A pointer to an optional `LLM_SESSION` structure that specifies extended configuration options for the client session. This structure can be used to define parameters such as the base URL, model name, authentication information, timeout values, token limits and sampling settings. If this parameter is omitted, or is NULL, the method will use session information from a previous call to **CreateSession**.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **ConnectEx** method creates a client session using the configuration specified in the *lpSession* structure. This provides more control over how the connection is established compared to **Connect**, and is intended for applications that require advanced configuration.

A version of this method can be called without any parameters. In this case, it will use default options and the session information specified with a previous call to the **CreateSession** method.

The *dwProviderId* parameter specifies the numeric identifier assigned to a supported provider. Provider identifiers are predefined constants built into the library and are assigned fixed values beginning at 1 and increasing sequentially for each provider. These identifiers are stable and are intended to uniquely identify a provider regardless of its display name. Applications should use the predefined constants (such as `LLM_PROVIDER_OPENAI` or `LLM_PROVIDER_MICROSOFT`) rather than hard-coding numeric values directly in source code.

Refer to the providers page for a list of supported service providers and their default models.

The *lpSession* parameter allows the application to specify connection parameters such as the provider endpoint, model name, API key, timeout values, token limits and sampling options. Any values not explicitly specified will use provider defaults. If this parameter is NULL, the method will use the internal LLM_SESSION structure allocated using the **CreateSession** method. If the *lpSession* parameter is NULL, and you have not called **CreateSession**, the method will fail.

The library makes an internal copy of the string members in the LLM_SESSION structure when the connection is established. The application does not need to retain them after the call to **ConnectEx** returns.

This method will block the calling thread until the connection has been established or the timeout period has elapsed. Applications should avoid calling this method on the main user interface thread. For best results, create a worker thread to establish the connection, especially when multiple

connections are required.

The connection established by this method represents a logical session. Depending on the provider and options specified, the underlying HTTP connection may be reused across requests or recreated as needed. Options such as `LLM_OPTION_KEEPALIVE` can be used to control connection behavior.

If the class instance is connected to another provider, this method will explicitly close that connection by calling the **Disconnect** method prior to establishing the new connection. If the connection fails, the **GetHandle** method will return INVALID_HANDLE.

The client handle returned by this method is owned by the thread that created it. To transfer ownership to another thread, use the **AttachThread** method.

Example

```
#include "cstools12.h"
#include <stdio.h>

int _tmain(void)
{
    CLlmClient llmClient;

    // Provide basic session information
    // Additional options such as temperature, token limits and timeouts
    // can be configured using members of the LLM_SESSION structure
    LLM_SESSION sessionInfo;

    ZeroMemory(&sessionInfo, sizeof(sessionInfo));
    sessionInfo.dwSize = sizeof(sessionInfo);
    sessionInfo.lpszModelName = _T("gpt-5.4-nano");
    sessionInfo.lpszApiKey = _T("%OPENAI_API_KEY%");
    sessionInfo.lpszSystemPrompt = _T("You are a helpful assistant.");

    // Establish a connection to OpenAI using a lightweight model
    // with the default connection options
    BOOL bConnected = llmClient.ConnectEx(
                          LLM_PROVIDER_OPENAI,
                          LLM_OPTION_DEFAULT,
                          &sessionInfo);

    if (!bConnected)
    {
        DWORD dwError = LlmGetLastError();
        _tprintf(_T("Unable to connect, error %lu\n"), dwError);
        return 1;
    }

    TCHAR szResponse[4096] = {0};
    DWORD dwResponseLength = _countof(szResponse); // number of TCHARs
    DWORD dwMessageId = 0;

    // Send a simple message to the model
    if (llmClient.SendMessage(
                      _T("What is the capital city of Denmark?"),
                      szResponse,
                      &dwResponseLength,
                      &dwMessageId))
    {
        _tprintf(_T("Response:\n%s\n"), szResponse);
```

```
    }
    else
    {
        dwError = llmClient.GetLastError();
        _tprintf(_T("Request failed, error %lu\n"), dwError);
    }

    // Close the connection explicitly
    llmClient.Disconnect();
    return 0;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

CLlmClient::ConvertTimestamp Method

```
BOOL ConvertTimestamp(
   TIME_T tTimestamp,
   LPSYSTEMTIME lpSystemTime
   BOOL bLocalTime
);
```

The **ConvertTimestamp** method converts a message or response timestamp to a SYSTEMTIME structure.

Parameters

tTimestamp

A 64-bit timestamp value associated with a message or response. This value represents the number of seconds that have elapsed since January 1, 1970 UTC.

lpSystemTime

A pointer to a `SYSTEMTIME` structure that receives the converted date and time value.

bLocalTime

If this parameter is non-zero, the timestamp is converted to the local system time. If this parameter is zero, the timestamp is converted to Coordinated Universal Time (UTC).

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **ConvertTimestamp** method converts an internal timestamp value used by the library into a standard `SYSTEMTIME` structure. This allows applications to display message and response times in a human-readable format. These timestamps are used in the client history of requests sent to the model and the responses it returned.

The *tTimestamp* parameter is a standard 64-bit Unix time value and can be used interchangeably with functions in the C standard library such as **gmtime** or **localtime**. Because it is a 64-bit integer, it is not impacted by the Year 2038 problem. Timestamps are returned by functions such as **LlmSendMessage** and can be converted into a local date and time using the **LlmConvertTimestamp** function.

The converted time can be returned as either local time or UTC by specifying the *bLocalTime* parameter. Applications should use local time for display purposes and UTC when storing or comparing timestamps across systems. The SYSTEMTIME value can be formatted using standard Windows functions such as **GetDateFormatEx** and **GetTimeFormatEx** to display locale-specific date and time values.

If you wish to convert the message timestamp to a standardized ISO 8601 string value, use the **FormatTimestamp** method.

Example

```
// Enumerate the message history and display message details
LLM_MESSAGE clientMessage = { sizeof(LLM_MESSAGE), 0 };
LLM_RESPONSE serverResponse = { sizeof(LLM_RESPONSE), 0 };
```

```
if (llmClient.GetFirstMessage(&clientMessage, &serverResponse))
{
    do
    {
        SYSTEMTIME stMessage = {0};
        TCHAR szDate[64] = {0};
        TCHAR szTime[64] = {0};

        llmClient.ConvertTimestamp(clientMessage.tTimestamp, &stMessage, TRUE);

        GetDateFormat(LOCALE_USER_DEFAULT, 0,
                      &stMessage, NULL,
                      szDate, _countof(szDate));

        GetTimeFormat(LOCALE_USER_DEFAULT, 0,
                      &stMessage, NULL,
                      szTime, _countof(szTime));

        _tprintf(_T("\nMessage %u\n"), clientMessage.dwMessageId);
        _tprintf(_T("  Timestamp:       %s %s\n"), szDate, szTime);
        _tprintf(_T("  Input Tokens:    %u\n"), clientMessage.nInputTokens);
        _tprintf(_T("  Content Length:  %u\n"), clientMessage.nContentLength);
        _tprintf(_T("  Content:         \"%s\"\n"), clientMessage.lpszContent);

        SYSTEMTIME stResponse = {0};
        llmClient.ConvertTimestamp(serverResponse.tTimestamp, &stResponse, TRUE);

        GetDateFormat(LOCALE_USER_DEFAULT, 0,
                      &stResponse, NULL,
                      szDate, _countof(szDate));

        GetTimeFormat(LOCALE_USER_DEFAULT, 0,
                      &stResponse, NULL,
                      szTime, _countof(szTime));

        _tprintf(_T("\nResponse %u\n"), serverResponse.dwMessageId);
        _tprintf(_T("  Timestamp:       %s %s\n"), szDate, szTime);
        _tprintf(_T("  Elapsed:         %u ms\n"), serverResponse.dwElapsed);
        _tprintf(_T("  Output Tokens:   %u\n"), serverResponse.nOutputTokens);
        _tprintf(_T("  Content Length:  %u\n"), serverResponse.nContentLength);
        _tprintf(_T("  Content:         \"%s\"\n"), serverResponse.lpszContent);
        _tprintf(_T("  Response ID:     %s\n"), (serverResponse.lpszResponseId ?
serverResponse.lpszResponseId : _T("None")));
        _tprintf(_T("  Model Name:      %s\n"), (serverResponse.lpszModelName ?
serverResponse.lpszModelName : _T("None")));
        _tprintf(_T("  Status Text:     %s\n"), (serverResponse.lpszStatusText ?
serverResponse.lpszStatusText : _T("None")));
    }
    while (llmClient.GetNextMessage(&clientMessage, &serverResponse));
}
```

This example uses the **GetDateFormat** and **GetTimeFormat** functions for simplicity and compatibility with both ANSI and Unicode builds. On current Windows platforms, applications should prefer using **GetDateFormatEx** and **GetTimeFormatEx**, which provide improved locale support and are recommended for new development. Note that these newer functions are implemented as Unicode-only APIs.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

CLlmClient::CreateSession Method

```
BOOL CreateSession(
   DWORD dwProviderId,
   LPCTSTR lpszBaseUrl,
   LPCTSTR lpszModelName,
   LPCTSTR lpszApiKey,
   LPCTSTR lpszApiVersion
);

BOOL CreateSession(
   DWORD dwProviderId,
   LPCTSTR lpszBaseUrl,
   LPCTSTR lpszModelName,
   LPCTSTR lpszApiKey,
   LPCTSTR lpszApiVersion,
   LPCTSTR lpszSystemPrompt,
   LONG nMaxTokens,
   FLOAT fTemperature,
   FLOAT fTopP
);
```

The **CreateSession** method allocates and initializes an internal `LLM_SESSION` structure using the specified connection parameters.

Parameters

dwProviderId

Specifies the service provider. This parameter must be one of the `LLM_PROVIDER` constants. Refer to the providers page for a list of supported providers and their default models.

lpszBaseUrl

A pointer to a null-terminated string that specifies the base URL for the provider endpoint. This parameter may be NULL to use the default endpoint for the selected provider. Some providers, such as Microsoft Foundry or local services, require a specific base URL.

lpszModelName

A pointer to a null-terminated string that specifies the model name to use for the session. This parameter may be NULL to use the provider default model, if one is defined. Providers without a default model require an explicit model name.

lpszApiKey

A pointer to a null-terminated string that specifies the API key used to authenticate with the provider. The API key may be provided using a literal string, an environment variable, or a value stored in the Windows Credential Manager. Using an environment variable or secure credential storage is recommended for production applications to avoid exposing sensitive information in source code or application binaries.

lpszApiVersion

A pointer to a null-terminated string that specifies the API version required by the provider. This parameter may be NULL if the provider does not require an explicit version. Some providers, such as Anthropic or Microsoft, may require a version string when establishing a connection.

lpszSystemPrompt

A pointer to a null-terminated string that specifies the system prompt used to provide instructions

to the model. This parameter may be NULL if no system prompt is required.

nMaxTokens

The maximum number of tokens that may be generated in the response. Specify zero to use the provider or model default.

fTemperature

The temperature value used to control response variability. Lower values produce more predictable responses, while higher values allow more variation. Specify `LLM_TEMPERATURE_DEFAULT` to use the default value.

fTopP

The nucleus sampling value used to limit token selection based on probability. Specify `LLM_TOP_P_DEFAULT` to use the default behavior. Most applications should leave this value at the default unless they specifically need to tune sampling behavior.

lppSession

A pointer to a variable that receives a pointer to an allocated `LLM_SESSION` structure. On successful return, this parameter will contain a pointer to a structure that can be passed to **ConnectEx**. The structure must be released using the **DeleteSession** method when it is no longer needed.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **CreateSession** method allocates and initializes an internal `LLM_SESSION` structure for the class instance using the specified parameters. This method is used in conjunction with the **ConnectEx** method when an application requires extended session configuration.

The memory allocated for the session structure will be released when the class destructor is invoked. The **DeleteSession** method can be used to immediately free this memory after a connection has been established, but this is not required.

It is important to note that the class owns the memory allocated for this structure, and there can only be one session structure allocated for each class instance. Your application should never attempt to explicitly free the pointer returned by this method and you should not retain a copy of the pointer. The **GetSession** method can be used to retrieve a pointer to the current session structure if one has been allocated.

Example

```
#include "cstools12.h"
#include <stdio.h>

int _tmain(void)
{
    CLlmClient llmClient;
    DWORD dwError = NO_ERROR;

    // Create a session for the class instance
    if (!llmClient.CreateSession(
            LLM_PROVIDER_OPENAI,
            NULL,                       // Default URL
            _T("gpt-5.4-nano"),         // Model name
            _T("%OPENAI_API_KEY%"))     // API key
```

```
    {
        dwError = llmClient.GetLastError();
        _tprintf(_T("Unable to create session, error %lu\n"), dwError);
        return 1;
    }

    // Establish a connection using the ConnectEx method;
    // when called without any arguments, it will use the
    // session that was just created
    if (!llmClient.ConnectEx())
    {
        dwError = llmClient.GetLastError();
        _tprintf(_T("Unable to connect, error %lu\n"), dwError);
        return 1;
    }

    TCHAR szResponse[4096] = {0};
    DWORD dwResponseLength = _countof(szResponse);
    DWORD dwMessageId = 0;

    if (llmClient.SendMessage(
                        _T("What is the capital city of Denmark?"),
                        szResponse,
                        &dwResponseLength,
                        &dwMessageId))
    {
        _tprintf(_T("Response:\n%s\n"), szResponse);
    }
    else
    {
        dwError = LlmGetLastError();
        _tprintf(_T("Request failed, error %lu\n"), dwError);
    }

    llmClient.Disconnect();
    return 0;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

ConnectEx, DeleteSession, GetSession, SendMessage, LLM_SESSION

CLlmClient::DeleteSession Method

```
BOOL DeleteSession();
```

The **DeleteSession** method releases an `LLM_SESSION` structure previously allocated by **CreateSession**.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **DeleteSession** method releases the memory allocated for an `LLM_SESSION` structure created by **CreateSession**.

After a session structure has been used with **ConnectEx**, it may be deleted immediately. The library makes an internal copy of the session configuration when the client session is created, so the original structure does not need to remain allocated for the lifetime of the client handle.

This method does not disconnect an active client session. To close a connection created by **Connect** or **ConnectEx**, call **Disconnect**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

CLImClient::DetachHandle Method

```
HCLIENT DetachHandle();
```

The **DetachHandle** method detaches the client handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the client handle associated with the current instance of the class object. If there is no active client session, the value INVALID_CLIENT will be returned.

Remarks

This method is used to detach a client handle created by the class for use with the SocketTools API. Once the client handle is detached from the class, no other class methods may be called. Note that the handle must be explicitly released at some later point by the process or a resource leak will occur.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

See Also

AttachHandle, GetHandle

CLlmClient::DisableTrace Method

```
BOOL DisableTrace();
```

The **DisableTrace** method disables the logging of network function calls.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, a value of zero is returned.

Remarks

This method will disable output to the log file for the current thread or process, depending on the flags used when logging was enabled. If this method is not called, the resources that were allocated for the logging session will be released when the process ends.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

CLlmClient::Disconnect Method

```
INT Disconnect();
```

The **Disconnect** method closes the connection and releases the memory allocated for the client session.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is LLM_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **Disconnect** method closes the active connection and releases all memory and resources associated with the specified client session, including the conversation history, cached message and response data, provider information and any other state maintained by the class instance. To preserve information from the session, retrieve it before calling this method.

Avoid calling this method while a blocking request is in progress. If a request must be canceled, call the **Cancel** method first and wait for the blocking operation to return before disconnecting the client session. The **IsBlocking** method can tell you if the class is in the middle of processing a blocking operation, such as retrieving the response to a message prompt.

Requirements

CLlmClient::EnableTrace Method

```
BOOL EnableTrace(
   LPCTSTR lpszTraceFile,
   DWORD dwTraceFlags
);
```

The **EnableTrace** method enables the logging of network function calls to a file.

Parameters

lpszTraceFile

A null-terminated string which specifies the name of the logfile which will be appended to or created. It is recommended that this file always specify an absolute path to avoid any ambiguity. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
TRACE_INFO	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
TRACE_ERROR	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
TRACE_HEXDUMP	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
TRACE_TRUNCATE	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for

	multithreaded applications that are using worker threads.

Return Value

If the method succeeds, the return value is non-zero. A return value of zero indicates an error, typically because the file could not be opened or created by the current process.

Remarks

Logging is enabled and disabled at the thread or process level, depending on the flags passed to this method, and is not associated with a specific client session. When logging is enabled, the information is appended to the specified file. If the file does not exist, it will be created. To limit the size of the file, enable and disable logging only around those sections of code that you wish to debug. If you do not provide a full path to the file, it will be relative to the current working directory for the process. This can produce unexpected results in multithreaded applications because the current directory is global to the entire process and can be changed by any thread at any time.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

The TRACE_HEXDUMP option can generate very large files because it includes all of the data exchanged between your application and the remote host. The TRACE_TRUNCATE option is only evaluated when logging is first enabled for a thread or process. If logging is already active, specifying this option will have no effect.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the method and the method's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "**0x**". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxxx:xxxx::xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, a connection is being made to a system with the IPv4 address 192.0.0.1 on port 1234.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

CLlmClient::EnumModels Method

```
LONG EnumModels(
   LPLLM_MODEL_INFO lpModelList,
   LONG nMaxModels,
   DWORD dwOptions
);
```

The **EnumModels** method returns a list of available models which match the provided options.

Parameters

lpModelList

A pointer to an array of LLM_MODEL_INFO structures that will receive information about the models which match the specified options. This parameter may be NULL, in which case the method only returns the number of matching models.

nMaxModels

The maximum number of LLM_MODEL_INFO structures in the array specified by the ***lpModelList*** parameter. If ***lpModelList*** is NULL, this value should be zero.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
LLM_MODEL_OPTION_DEFAULT	Returns the default list of chat models for the connected provider.
LLM_MODEL_OPTION_PREVIEW	Include preview or experimental models.
LLM_MODEL_OPTION_STREAMING	Include models that support streaming responses.
LLM_MODEL_OPTION_STRUCTURED	Include models that support structured output, such as JSON mode or schema-constrained responses.
LLM_MODEL_OPTION_REASONING	Include models that support reasoning-oriented generation.
LLM_MODEL_OPTION_VISION	Include models that support image input.
LLM_MODEL_OPTION_AUDIO	Include models that support audio output, such as text-to-speech.
LLM_MODEL_OPTION_IMAGE	Include models that support image generation.
LLM_MODEL_OPTION_VIDEO	Include models that support video generation.
LLM_MODEL_OPTION_TRANSCRIPTION	Include models that support audio transcription, such as speech-to-text.
LLM_MODEL_OPTION_DEPRECATED	Include deprecated, retired, or legacy models that are not normally returned.
LLM_MODEL_OPTION_ALL_MODELS	Include all known model types for the connected provider.

Return Value

If the method succeeds, the return value is the number of models which match the specified options. If the method fails, the return value is LLM_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **EnumModels** method enumerates the models available for the provider associated with the client session. The client must have been successfully connected before calling this method. The returned list is based on the provider metadata available to the library and, when supported by the provider, information returned by the provider itself.

To determine how many models match the specified options, call this method with the *lpModelList* parameter set to NULL and the *nMaxModels* parameter set to zero. If the method succeeds, the return value is the number of matching models. You can then allocate an array of LLM_MODEL_INFO structures and call the method again to retrieve the model information.

Each LLM_MODEL_INFO structure should have its *dwSize* member initialized to the size of the structure before calling this method. This enables the library to validate the structure version and maintain compatibility with future releases.

The model list may be cached for a limited period of time to avoid unnecessary requests to the provider. Use **GetCacheTime** and **SetCacheTime** to determine or change the cache lifetime for the client session.

The model capabilities reported by this method are intended to help an application select an appropriate model. Providers may change their model availability, capabilities, or status over time, and the provider remains the final authority on whether a specific model can be used for a request.

Example

```
LONG nModels = llmClient.EnumModels(LLM_MODEL_OPTION_DEFAULT);

if (nModels > 0)
{
    LPLLM_MODEL_INFO lpModelList;

    lpModelList = (LPLLM_MODEL_INFO)calloc(nModels, sizeof(LLM_MODEL_INFO));

    if (lpModelList != NULL)
    {
        for (LONG nIndex = 0; nIndex < nModels; nIndex++)
            lpModelList[nIndex].dwSize = sizeof(LLM_MODEL_INFO);

        nModels = llmClient.EnumModels(lpModelList, nModels,
LLM_MODEL_OPTION_DEFAULT);

        if (nModels != LLM_ERROR)
        {
            for (LONG nIndex = 0; nIndex < nModels; nIndex++)
                _tprintf(_T("%s\n"), lpModelList[nIndex].szName);
        }

        free(lpModelList);
    }
}
else if (nModels == LLM_ERROR)
```

```
{
    DWORD dwError = LlmGetLastError();
    _tprintf(_T("Unable to enumerate models, error 0x%08lx\n"), dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

CLlmClient::EnumProviders Method

```
LONG EnumProviders(
   LPLLM_PROVIDER_INFO lpProviderList,
   LONG nMaxProviders
);
```

The **EnumProviders** method returns a list of supported service providers.

Parameters

lpProviderList

A pointer to an array of LLM_PROVIDER_INFO structures that will receive information about the supported providers. This parameter may be NULL, in which case the method only returns the number of providers.

nMaxProviders

The maximum number of LLM_PROVIDER_INFO structures in the array specified by the *lpProviderList* parameter. If *lpProviderList* is NULL, this value should be zero.

Return Value

If the method succeeds, the return value is the number of providers. If the method fails, the return value is LLM_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **EnumProviders** method returns information about the LLM service providers supported by the library. This includes the provider identifier, provider name, host name, default model name, protocol, port number, and capability flags.

To determine how many providers are available, call this method with the *lpProviderList* parameter set to NULL and the *nMaxProviders* parameter set to zero. If the method succeeds, the return value is the number of providers. You can then allocate an array of LLM_PROVIDER_INFO structures and call the method again to retrieve the provider information.

Each LLM_PROVIDER_INFO structure should have its *dwSize* member initialized to the size of the structure before calling this method. This enables the library to validate the structure version and maintain compatibility with future releases.

The list returned by this method only identifies providers that are known to the library. It does not verify that the provider is currently reachable, that an account is active, or that a valid API key has been configured.

Example

```
LONG nProviders = llmClient.EnumProviders();

if (nProviders > 0)
{
    LPLLM_PROVIDER_INFO lpProviderList;

    lpProviderList = (LPLLM_PROVIDER_INFO)calloc(nProviders,
sizeof(LLM_PROVIDER_INFO));

    if (lpProviderList != NULL)
    {
        for (LONG nIndex = 0; nIndex < nProviders; nIndex++)
```

```
            lpProviderList[nIndex].dwSize = sizeof(LLM_PROVIDER_INFO);

        nProviders = llmClient.EnumProviders(lpProviderList, nProviders);

        if (nProviders != LLM_ERROR)
        {
            for (LONG nIndex = 0; nIndex < nProviders; nIndex++)
                _tprintf(_T("%s\n"), lpProviderList[nIndex].szDisplayName);
        }

        free(lpProviderList);
    }
}
else if (nProviders == LLM_ERROR)
{
    DWORD dwError = LlmGetLastError();
    _tprintf(_T("Unable to enumerate providers, error 0x%08lx\n"), dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

CLlmClient::EstimateTokenCount Method

```
LONG EstimateTokenCount(
   DWORD dwProviderId
   LPCTSTR lpszMessageText,
   INT cchMessageText
);
```

The **EstimateTokenCount** method estimates the number of tokens in a string.

Parameters

dwProviderId

The identifier of the provider used to estimate the token count. This value determines the tokenization rules that are applied, as different providers may use different tokenization algorithms.

lpszMessageText

A pointer to a null-terminated string containing the text to be analyzed. This parameter cannot be NULL.

cchMessageText

The number of characters in the string specified by the ***lpszMessageText*** parameter. If this value is -1, the string is assumed to be null-terminated.

Return Value

If the method succeeds, the return value is the estimated number of tokens in the specified string. If there are no text characters, or the string only contains whitespace, the method will return zero. If the method fails, the return value is LLM_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **EstimateTokenCount** method provides an approximate count of the number of tokens that would be required to represent the specified text for a given provider. This can be useful when estimating prompt size and ensuring that requests remain within model limits.

The ***lpszMessageText*** parameter must contain valid Unicode text and cannot contain arbitrary binary data or embedded null characters. If malformed Unicode is detected, the method will fail and return LLM_ERROR, with the last error code set to ST_ERROR_INVALID_UNICODE. If the string consists only of whitespace characters, including non-breaking spaces, the method will return zero.

The ANSI version of this method expects the input string to contain either ASCII or UTF-8 encoded text. Strings encoded using a localized ANSI code page are not supported and may fail validation if they contain non-ASCII characters. To ensure internationalized text is processed correctly, it is recommended that your project use Unicode whenever possible.

A token is a unit of text used internally by large language models. Tokens are not the same as characters or words. In general, a token may represent a single word, part of a word, or a short sequence of characters. For example, common words may be represented as a single token, while less common or longer words may be split into multiple tokens. Punctuation and whitespace may also be represented as separate tokens.

As a general rule of thumb, one token corresponds to approximately three to four characters of English text. This can vary significantly depending on the content, language, and tokenization rules used by the provider.

Most providers distinguish between input tokens (the text sent to the model) and output tokens (the

text generated by the model in response). Usage and billing are typically based on the total number of tokens processed, including both the prompt and the generated response. Monitoring token usage can help applications control costs and ensure that requests remain within the limits imposed by the selected model.

The tokenization rules used by each provider can vary, and the exact number of tokens used in a request is determined by the provider at runtime. The value returned by this method is an estimate only and should not be relied on as an exact measurement.

This method does not require an active client session and can be used independently to estimate token usage before establishing a connection or sending a request.

To determine how many input and output tokens have been used in a session, use the **GetTokenUsage** method.

Example

```
LPCTSTR lpszText = _T("Explain how a TCP connection is established.");

LONG nTokens = llmClient.EstimateTokenCount(LLM_PROVIDER_OPENAI, lpszText, -1);

if (nTokens != LLM_ERROR)
{
    _tprintf(_T("Estimated token count: %d\n"), nTokens);
}
else
{
    DWORD dwError = LlmGetLastError();
    _tprintf(_T("Unable to estimate token count, error 0x%08lx\n"), dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

CLlmClient::ExportHistory Method

```
BOOL ExportHistory(
   LPCTSTR lpszFileName,
   LONG nMessageCount,
   LPLONG lpnExported
);

BOOL ExportHistory(
   LPCTSTR lpszFileName,
   LPLONG lpnExported
);
```

The **ExportHistory** method exports the conversation history to a JSON-formatted file.

Parameters

lpszFileName

A pointer to a null-terminated string which specifies the name of the file to be created. This parameter cannot be NULL or a zero-length string.

nMessageCount

The number of the most recent messages and responses which should be exported. If this parameter is omitted or the value is zero, all messages in the current conversation are exported.

lpnExported

A pointer to an integer which will receive the number of messages which were exported when the method returns. If this information is not required, this parameter may be omitted.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **ExportHistory** method exports the current conversation history associated with the client session to a JSON-formatted file. The exported history includes both client messages and model responses stored in the current session history.

This method only exports conversation history currently stored in memory for the client session. It cannot be used if the conversation history has been disabled by setting the history size to zero.

If the *lpszFileName* parameter specifies a directory or device name, the method will fail. It is permitted to use environment variables in the file name by surrounding the variable name with the percent symbol. If the file name contains any leading or trailing space characters, they will be removed. If the file already exists, the current process must have permission to overwrite the file. If the file has the read-only attribute set, the method will fail and the last error code will be set to `ST_ERROR_ACCESS_DENIED`.

If the *nMessageCount* parameter is non-zero, the method exports only the most recent messages in the conversation history. Older messages are skipped. If the specified count exceeds the number of available messages, all available messages are exported.

The exported file uses UTF-8 encoded JSON text and is intended to be human-readable. Applications should not depend on the exact formatting or internal structure of the file because future versions of the library may include additional metadata or fields. To help prevent data loss, the method writes the

exported history to a temporary file and only replaces the destination file after the export operation has completed successfully. If the export fails, any existing file specified by the *lpszFileName* parameter is left unchanged.

The exported file is intended to provide a simple mechanism for persisting conversation state between application sessions. A previously exported history file can later be restored using the **ImportHistory** method.

Important: The conversation history may contain sensitive or private information. Applications should take reasonable precautions to protect exported history files, such as limiting access permissions or encrypting the exported file. Applications which allow users to export conversation history should consider informing users that the exported file may contain private information.

Example

```
LONG nExported = 0;

// Export the complete conversation history to a JSON file
if (llmClient.ExportHistory(
                    _T("%USERPROFILE%\\Documents\\conversation.json"),
                    &nExported))
{
    _tprintf(_T("Exported %ld messages\n"), nExported);
}
else
{
    DWORD dwError = llmClient.GetLastError();
    _tprintf(_T("Unable to export conversation history, error 0x%08lX\n"),
dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

CLlmClient::FindMessage Method

```
DWORD FindMessage(
   LPCTSTR lpszPattern,
   DWORD dwStartMessageId,
   DWORD dwOptions
);
```

The **FindMessage** method searches the client conversation history for matching text.

Parameters

lpszPattern

A null-terminated string which specifies the text that should be searched for. This may be a literal string or it may specify a simplified regular expression. The search options can be used to specify if the search is case-sensitive. This parameter cannot be NULL or a string which only contains whitespace.

dwStartMessageId

An unsigned integer which specifies the message ID that the search should begin with. If this parameter value is zero, the search begins with the oldest message in the client history.

dwOptions

An unsigned integer that specifies one or more search options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
LLM_SEARCH_DEFAULT	Search the entire message history for matching text.
LLM_SEARCH_PROMPT	Search the history of message prompts for matching text.
LLM_SEARCH_CASE_SENSITIVE	The pattern match will be case-sensitive. If this option is not specified, matches are not case-sensitive.
LLM_SEARCH_LITERAL_MATCH	Perform a literal string search instead of using a regular expression.

Return Value

If a matching message is found, the method returns a non-zero message ID. If no message prompts and/or responses match the search pattern, the method returns zero. To get extended error information, call **GetLastError**.

Remarks

The **FindMessage** method searches the message history for text that matches a specific pattern. The search can be limited to prompts, responses, or both, depending on the options specified by the *dwOptions* parameter. The pattern you are matching against must be a null-terminated string and it cannot consist of only whitespace characters (spaces, tabs, carriage returns and linefeeds).

If the *dwStartMessageId* parameter is non-zero, the method will begin searching with the first message whose identifier is equal to or greater than the specified value. Message identifiers are unique within a client session and are assigned incrementally, so newer messages will always have higher identifier values than older messages.

If the *lpszPattern* parameter does not contain any regular expression constructs (such as **^**, **$**, **[ ]**, or quantifiers like and), the search is performed using a simple substring comparison. Regular

* +
expression matching is automatically enabled when the pattern contains recognized regular expression constructs, unless the LLM_SEARCH_LITERAL_MATCH option is specified.

If a regular expression pattern is specified, the method compiles the pattern and searches the message content for a match. The regular expression matching uses a simplified version which only supports anchors, wildcards, match classes (enclosed in brackets) and a limited number of escape sequences such as **\d** to match any digit or **\s** to match any space character. It does not support grouping or replacement.

Supported regular expression constructs include:

- The caret **^** and dollar symbol **$** for the beginning and end of the content.
- The period **.** to match any character.
- Character classes such as **[abc]** which would match any of the characters enclosed in brackets.
- Negated classes such as **[^abc]** which would match if none of those characters are found.
- Escaped matches such as **\d** for digits, **\w** for word characters and **\s** for whitespace characters
- The **+** quantifier can be used to match one or more occurrences.
- The ***** quantifier will match zero or more occurrences.

This method uses a minimal regular expression parser and does not include support for complex constructs such as grouping, backreferences or alternation using the pipe **|** character. If you want to search for text which may contain characters typically used in regular expressions such as **[** or **$**, you can either escape them using a backslash, or you can use the LLM_SEARCH_LITERAL_MATCH option which forces the method to only perform a substring search.

Applications searching for arbitrary user-entered text should usually specify the LLM_SEARCH_LITERAL_MATCH option to avoid unintended interpretation of regular expression characters. This will avoid situations where a user may unexpectedly enter search text which appears to be a regular expression pattern.

Regular expression matches are performed against the entire prompt or response text and are not implicitly anchored. It is also important to keep in mind that matches can span multiple lines (they do not end at line breaks) and will attempt to match as much text as possible (this is sometimes referred to as a "greedy match"). This can yield unexpected results if you use wildcards in the pattern which are overly broad, matching large sections of the prompt or response text. For example, a pattern like ".*abc" will match everything until the last instance of "abc" is found.

If you are calling this method in C, C++ or another C-like language and want to use a backslash in your regular expression, remember you will need to escape the backslash (in other words, use double backslashes). For example, if you wanted to use the regular expression \d+\s+ in your pattern, the C string literal would look like "\\d+\\s+", otherwise the compiler will probably warn you about unrecognized escape sequences.

If neither the LLM_SEARCH_PROMPT nor LLM_SEARCH_RESPONSE options are explicitly specified, the search will match against both message prompts and responses.

The **GetMessageById** method can be used to obtain the complete contents of the prompt and/or response for a matching message.

Example

```
LPCTSTR lpszPattern = _T("exception.*handler");
DWORD dwOptions = LLM_SEARCH_DEFAULT;
DWORD dwMessageId = 0;
```

```
// Find the first message that contains the specified text
dwMessageId = llmClient.FindMessage(lpszPattern, dwMessageId, dwOptions))

if (dwMessageId != 0)
{
    _tprintf(_T("Found match in message ID %lu\n"), dwMessageId);

    // Continue searching for additional matches
    do
    {
        dwMessageId = llmClient.FindMessage(lpszPattern, dwMessageId + 1,
dwOptions);

        if (dwMessageId != 0)
            _tprintf(_T("Found another match in message ID %lu\n"), dwMessageId);
    }
    while (dwMessageId != 0);
}
else
{
    _tprintf(_T("No matching messages were found.\n"));
}
```

CLlmClient::FormatTimestamp Method

```
BOOL INT LlmFormatTimestamp(
   TIME_T tTimestamp,
   LPTSTR lpszDateTime,
   INT nMaxLength,
   BOOL bLocalTime
);

BOOL INT LlmFormatTimestamp(
   TIME_T tTimestamp,
   CString &strDateTime,
   BOOL bLocalTime
);
```

The **FormatTimestamp** method returns a timestamp value as an ISO 8601 formatted date and time string.

Parameters

tTimestamp

A 64-bit timestamp value associated with a message or response. This value represents the number of seconds that have elapsed since January 1, 1970 UTC.

lpszDateTime

A pointer to a buffer that receives the formatted date and time string. This parameter cannot be NULL and must be large enough to store the entire string, including the terminating null character. An alternate version of this method accepts a **CString** object which will contain the formatted timestamp when the method returns.

nMaxLength

The size of the buffer specified by the lpszDateTime parameter, in characters. This value must be large enough to store the formatted string. A buffer of at least 32 characters is recommended.

bLocalTime

If this parameter is non-zero, the timestamp is converted to the local system time before formatting. If this parameter is zero, the timestamp is formatted as Coordinated Universal Time (UTC).

Return Value

If the method succeeds, the return value is the number of characters copied into the string buffer. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **FormatTimestamp** method converts a timestamp value returned by the library into a human-readable date and time string using the ISO 8601 format. This format is consistent, unambiguous, and suitable for logging, display, or storage.

The *tTimestamp* parameter is a standard 64-bit Unix time value and can be used interchangeably with functions in the C standard library such as `gmtime` or `localtime`. Because it is a 64-bit integer, it is not impacted by the Year 2038 problem. Timestamps are returned by methods such as **SendMessage** and can be converted into a local date and time using the **ConvertTimestamp** method.

The formatted string is returned in the form "YYYY-MM-DDThh:mm:ssZ" when UTC is specified. When local time is specified, the string is returned in the form "YYYY-MM-DDThh:mm:ss+hh:mm" or "YYYY-MM-DDThh:mm:ss-hh:mm", depending on the current time zone offset.

When ***bLocalTime*** is non-zero, the formatted string includes the local time zone offset. This ensures that the resulting value is not ambiguous and preserves the ISO 8601 format.

Applications that require locale-specific formatting or alternative date and time representations should convert the timestamp using **ConvertTimestamp** and apply additional formatting as needed. If you need to display the date and time using conventions for the current locale, use functions such as **GetDateFormatEx** and **GetTimeFormatEx** in the Windows API.

Example

```
// Enumerate the message history and display message details
LLM_MESSAGE clientMessage = { sizeof(LLM_MESSAGE), 0 };
LLM_RESPONSE serverResponse = { sizeof(LLM_RESPONSE), 0 };

if (llmClient.GetFirstMessage(&clientMessage, &serverResponse))
{
    do
    {
        TCHAR szDateTime[64] = {0};

        llmClient.FormatTimestamp(clientMessage.tTimestamp, szDateTime,
_countof(szDateTime), FALSE);

        _tprintf(_T("\nMessage %u\n"), clientMessage.dwMessageId);
        _tprintf(_T("  Timestamp:       %s\n"), szDateTime);
        _tprintf(_T("  Input Tokens:    %u\n"), clientMessage.nInputTokens);
        _tprintf(_T("  Content Length:  %u\n"), clientMessage.nContentLength);
        _tprintf(_T("  Content:         \"%s\"\n"), clientMessage.lpszContent);

        llmClient.FormatTimestamp(serverResponse.tTimestamp, szDateTime,
_countof(szDateTime), FALSE);

        _tprintf(_T("\nResponse %u\n"), serverResponse.dwMessageId);
        _tprintf(_T("  Timestamp:       %s\n"), szDateTime);
        _tprintf(_T("  Elapsed:         %u ms\n"), serverResponse.dwElapsed);
        _tprintf(_T("  Output Tokens:   %u\n"), serverResponse.nOutputTokens);
        _tprintf(_T("  Content Length:  %u\n"), serverResponse.nContentLength);
        _tprintf(_T("  Content:         \"%s\"\n"), serverResponse.lpszContent);
        _tprintf(_T("  Response ID:     %s\n"), (serverResponse.lpszResponseId ?
serverResponse.lpszResponseId : _T("None")));
        _tprintf(_T("  Model Name:      %s\n"), (serverResponse.lpszModelName ?
serverResponse.lpszModelName : _T("None")));
        _tprintf(_T("  Status Text:     %s\n"), (serverResponse.lpszStatusText ?
serverResponse.lpszStatusText : _T("None")));
    }
    while (llmClient.GetNextMessage(&clientMessage, &serverResponse));
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

CLlmClient::GetCacheTime Method

```
INT GetCacheTime();
```

The **GetCacheTime** method returns the current cache lifetime, in seconds, for the specified client session.

Parameters

None.

Return Value

If the method succeeds, the return value is the current cache time in seconds. If the method fails, the return value is LLM_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetCacheTime** method retrieves the amount of time, in seconds, that provider and model information is cached by the client session. Caching this information reduces the number of requests made to the provider and can improve performance when repeatedly querying for models or provider metadata.

By default, the cache lifetime for a client session is one hour (3600 seconds). The cache time can be adjusted using the **SetCacheTime** method. Shorter cache times will refresh provider and model information more frequently, while longer cache times can reduce network activity.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

CLlmClient::GetDefaultModelFlags Method

```
BOOL GetDefaultModelFlags(
   DWORD dwProviderId
   LPCTSTR lpszModelName,
   LPDWORD lpdwFlags
);
```

The **GetDefaultModelFlags** method returns the default capability flags for the specified model.

Parameters

dwProviderId

The identifier of the provider associated with the model.

lpszModelName

A null-terminated string which contains the name of the new model. If this parameter is NULL or a zero-length string, the default model for the specified provider will be used.

lpdwFlags

A pointer to an unsigned integer which may have one or more bit flags set when the function returns. If there are no capabilities defined for the specified model, this value will be set to `LLM_MODEL_FLAG_NONE`. This parameter cannot be NULL and the value does not need to be initialized by the caller.

Constant	Description
LLM_MODEL_FLAG_NONE	No model capabilities defined
LLM_MODEL_FLAG_CHAT	Supports conversational text generation
LLM_MODEL_FLAG_SYSTEM_ROLE	Accepts a system role message in the input
LLM_MODEL_FLAG_STREAMING	Supports streaming responses
LLM_MODEL_FLAG_STRUCTURED	Supports structured output (e.g., JSON or schema)
LLM_MODEL_FLAG_VISION	Supports image inputs (multimodal)
LLM_MODEL_FLAG_TOOLS	Supports tool or function calling
LLM_MODEL_FLAG_REASONING	Supports reasoning-oriented generation
LLM_MODEL_FLAG_RESPONSES	Supports the Responses API (unified endpoint)
LLM_MODEL_FLAG_FUNCTIONS	Supports OpenAI-style function calling with schemas
LLM_MODEL_FLAG_AUDIO	Supports audio output (text-to-speech)
LLM_MODEL_FLAG_IMAGE	Supports image generation
LLM_MODEL_FLAG_VIDEO	Supports video generation
LLM_MODEL_FLAG_TRANSCRIPTION	Supports speech-to-text transcription

LLM_MODEL_FLAG_INSTRUCTIONS	Supports a dedicated instruction field outside message lists
LLM_MODEL_FLAG_MAX_COMPLETION_TOKENS	Uses `max_completion_tokens` instead of `max_tokens` in requests
LLM_MODEL_FLAG_INFERRED	Capabilities are inferred rather than explicitly defined

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **LlmGetLastError**.

Remarks

The **GetDefaultModelFlags** method returns the default capability flags for a model associated with the specified provider. If the model name is recognized, the library will return the inferred capabilities associated with that model. If the model name is not recognized, the *dwFlags* parameter will return `LLM_MODEL_FLAG_NONE`.

This method does not require the application to be connected to a service provider. These capabilities are inferred from an internal table of recognized models and may not always reflect the current behavior of a provider, particularly when providers update, rename or replace models. The **GetModelFlags** method can be used to determine the capabilities of the model that was selected when a connection was established with a provider.

Because the capability flags are derived from the model name rather than explicitly provided by the service provider, the `LLM_MODEL_FLAG_INFERRED` flag will be set for recognized models.

To obtain the name of the default model the library uses for a specific provider, call the **GetDefaultModelName** method.

Example

```
DWORD dwProviderId = LLM_PROVIDER_OPENAI;
TCHAR szModelName[LLM_MODEL_NAMELEN] = _T("");

if (llmClient.GetDefaultModelName(dwProviderId, szModelName, _countof(szModelName))
> 0)
{
    DWORD dwFlags = LLM_MODEL_FLAG_NONE;

    if llmClient.GetDefaultModelFlags(dwProviderId, szModelName, &dwFlags))
    {
        if (dwFlags & LLM_MODEL_FLAG_REASONING)
            _tprintf(_T("The %s model has reasoning capability\n"), szModelName);
    }
    else
    {
        DWORD dwError = llmClient.GetLastError();
       _tprintf(_T("Unable to retrieve default model flags, error 0x%08lx\n"),
dwError);
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

EnumModels, GetDefaultModelName, GetModelInfo, ValidateModel

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CLlmClient::GetDefaultModelName Method

```
INT GetDefaultModelName(
   DWORD dwProviderId
   LPCTSTR lpszModelName,
   INT nMaxLength
);

INT GetDefaultModelName(
   DWORD dwProviderId
   CString &strModelName
);
```

The **GetDefaultModelName** method returns the name of the default model for a service provider.

Parameters

dwProviderId

The identifier of the provider whose default model name will be returned.

lpszModelName

A pointer to a buffer that receives the default model name. This parameter may be NULL, in which case the method returns the length of the model name without copying it. An alternate version of this method accepts a **CString** object which will contain the model name when the method returns.

nMaxLength

The size of the buffer specified by the ***lpszModelName*** parameter, in characters. If ***lpszModelName*** is NULL, this value should be zero.

Return Value

If the method succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetDefaultModelName** method returns the default model name associated with the specified provider. This is the model that will be used if a session is created or connected without explicitly specifying a model name. In most cases, the default model is selected to provide a balance of performance and cost, typically favoring smaller, faster models that are suitable for general use. For more information about providers and their default models, refer to the Large Language Model Providers section.

Applications can call this method to determine a suitable default model for a provider, or to present a default selection to the user. The default model may change over time as providers update or replace their models.

If the ***lpszModelName*** parameter is NULL, the method returns the length of the model name, in characters, not including the terminating null character. This allows an application to determine the required buffer size before retrieving the string.

The model name is returned as a null-terminated string. If a buffer is provided but is not large enough to receive the entire string, the method fails and sets the error code to ST_ERROR_BUFFER_TOO_SMALL. A buffer of 128 characters is typically sufficient for most model names.

Example

```
INT cchModelName = llmClient.GetDefaultModelName(LLM_PROVIDER_OPENAI);

if (cchModelName > 0)
{
    LPTSTR lpszModelName;
    lpszModelName = (LPTSTR)malloc((cchModelName + 1) * sizeof(TCHAR));

    if (lpszModelName != NULL)
    {
        if (llmClient.GetDefaultModelName(LLM_PROVIDER_OPENAI, lpszModelName,
cchModelName + 1) > 0)
        {
             _tprintf(_T("The default model is %s\n"), lpszModelName);
        }

        free(lpszModelName);
    }
}
else
{
    DWORD dwError = llmClient.GetLastError();
    _tprintf(_T("Unable to retrieve default model name, error 0x%08lx\n"),
dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

CLlmClient::GetDefaultUrl Method

```
INT GetDefaultUrl(
   DWORD dwProviderId,
   LPCTSTR lpszBaseUrl,
   INT nMaxLength
);

INT GetDefaultUrl(
   DWORD dwProviderId,
   CString &strBaseUrl
);
```

The **GetDefaultUrl** method returns the default endpoint URL for the specified provider.

Parameters

dwProviderId

Specifies the service provider. This parameter must be one of the **LLM_PROVIDER** constants. Refer to the providers page for a list of supported providers and their default models.

lpszBaseUrl

A pointer to a buffer that receives the default base endpoint URL used when making requests to the provider. If this parameter is NULL, the method will return the length of the URL without copying to the string buffer. An alternate version of this method accepts a reference to a **CString** object which will contain the endpoint URL when the method returns.

nMaxLength

The size of the buffer specified by the ***lpszBaseUrl*** parameter, in characters. If ***lpszBaseUrl*** is NULL, this value should be zero. If a buffer is provided, it must be large enough to store the complete URL, including the terminating null character.

Return Value

If the method succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetDefaultUrl** method returns the default base endpoint URL used when a client makes a request to the provider. If the provider ID is unknown or does not have a default endpoint, this method will return zero. If the provider does not have a default endpoint, the last error code will be set to ST_ERROR_NO_PROVIDER_BASE_URL. In this case, a client must always provide a URL endpoint.

To return the base endpoint URL being used with the current client session, use the **GetProviderUrl** method. The **GetDefaultUrl** method does not require an active client session and will only return the default endpoint for a specific provider. It will not return a custom endpoint specified for a provider.

The base URL is returned as a null-terminated string. If the buffer is not large enough to receive the entire string, the method fails and sets the error code to ST_ERROR_BUFFER_TOO_SMALL. We recommend a buffer size of at least 256 characters when retrieving the base URL.

Example

```
DWORD dwProviderId = LLM_PROVIDER_OPENAI;
TCHAR szDefaultUrl[256] = {0};
```

```
INT cchDefaultUrl = llmClient.GetDefaultUrl(dwProviderId, szDefaultUrl,
_countof(szDefaultUrl));

if (cchDefaultUrl > 0)
{
    _tprintf(_T("The default endpoint for provider %lu is %s\n"), dwProviderId,
szDefaultUrl);
}
else
{
    DWORD dwError = LlmGetLastError();
    _tprintf(_T("Unable to get the provider endpoint, error 0x%08lx\n"), dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

CLlmClient::GetErrorString Method

```
INT GetErrorString(
   DWORD dwErrorCode,
   LPTSTR lpszDescription,
   INT nMaxLength
);

INT GetErrorString(
   DWORD dwErrorCode,
   CString &strDescription
);
```

The **GetErrorString** method returns the description of a specific error code.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

The buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length.

nMaxLength

The maximum number of characters that may be copied into the description buffer.

Return Value

If the method succeeds, the return value is the length of the description string. If the method fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the method is invalid.

Remarks

This method is used in conjunction with the **GetLastError** method for use with warning dialogs or as diagnostic messages. Applications should not rely on the returned description text for program logic. Use the numeric error code for comparisons and handling specific conditions.

The error descriptions returned by this method are provided in English only. Applications that require localized error messages should provide their own translations based on the returned error code.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetLastError, SetLastError

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CLlmClient::GetFirstMessage Method

```
BOOL GetFirstMessage(
   LPLLM_MESSAGE lpMessage,
   LPLLM_RESPONSE lpResponse
);
```

The **GetFirstMessage** method returns the first available message in the conversation history.

Parameters

lpMessage

A pointer to an LLM_MESSAGE structure that receives information about the client request. This parameter may be NULL, in which case no message information is returned.

lpResponse

A pointer to an LLM_RESPONSE structure that receives information about the server response. This parameter may be NULL, in which case no response information is returned.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**. If there are no messages in the client history, the error code will be set to `ST_ERROR_END_OF_MESSAGES`.

Remarks

The **GetFirstMessage** method retrieves the first message and associated response from the client conversation history. This method is typically used in conjunction with the **GetNextMessage** method to enumerate all messages in the session.

If the *lpMessage* and/or *lpResponse* parameters are specified, their respective structures must be initialized with the *dwSize* member set to the size of the structure before calling this method. This enables the library to validate the structure version and maintain compatibility with future releases.

Messages are returned in chronological order, beginning with the oldest message in the client history. New messages are always appended to the end of the history, and if the history is trimmed, older messages are removed first. The order of messages is stable and reflects the sequence in which they were submitted.

If there are no messages in the client history, the method fails and sets the error code to ST_ERROR_END_OF_MESSAGES. Applications can use this condition to determine that no messages are available for enumeration.

Either the *lpMessage* or *lpResponse* parameter may be NULL if only one type of information is required. At least one of these parameters must be specified. If both parameters are NULL, the method fails and sets the error code to ST_ERROR_INVALID_PARAMETER.

Example

```
// Enumerate the message history and display message details
LLM_MESSAGE clientMessage = { sizeof(LLM_MESSAGE), 0 };
LLM_RESPONSE serverResponse = { sizeof(LLM_RESPONSE), 0 };

if (llmClient.GetFirstMessage(&clientMessage, &serverResponse))
{
    do
    {
```

```
        _tprintf(_T("\nMessage %u\n"), clientMessage.dwMessageId);
        _tprintf(_T("  Input Tokens:    %u\n"), clientMessage.nInputTokens);
        _tprintf(_T("  Content Length:  %u\n"), clientMessage.nContentLength);
        _tprintf(_T("  Content:         \"%s\"\n"), clientMessage.lpszContent);

        _tprintf(_T("\nResponse %u\n"), serverResponse.dwMessageId);
        _tprintf(_T("  Elapsed:         %u ms\n"), serverResponse.dwElapsed);
        _tprintf(_T("  Output Tokens:   %u\n"), serverResponse.nOutputTokens);
        _tprintf(_T("  Content Length:  %u\n"), serverResponse.nContentLength);
        _tprintf(_T("  Content:         \"%s\"\n"), serverResponse.lpszContent);
        _tprintf(_T("  Response ID:     %s\n"), (serverResponse.lpszResponseId ?
serverResponse.lpszResponseId : _T("None")));
        _tprintf(_T("  Model Name:      %s\n"), (serverResponse.lpszModelName ?
serverResponse.lpszModelName : _T("None")));
        _tprintf(_T("  Status Text:     %s\n"), (serverResponse.lpszStatusText ?
serverResponse.lpszStatusText : _T("None")));
    }
    while (llmClient.GetNextMessage(&clientMessage, &serverResponse));
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

CLlmClient::GetHandle Method

```
HCLIENT GetHandle();
```

The **GetHandle** method returns the client handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the client handle associated with the current instance of the class object. If there is no active client session, the value INVALID_CLIENT will be returned.

Remarks

This method is used to obtain the client handle created by the class for use with the SocketTools API.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

See Also

AttachHandle, DetachHandle, IsInitialized

CLlmClient::GetHeader Method

```
INT GetHeader(
   LPCTSTR lpszHeaderName,
   LPTSTR lpszHeaderValue,
   INT nMaxLength
);
```

The **GetHeader** method returns the value of an HTTP header from the server response.

Parameters

lpszHeaderName

A pointer to a null-terminated string which specifies the name of the HTTP response header. The header names are not case-sensitive. Header names may only contain ASCII letters, numbers and a restricted subset of punctuation characters. Header names cannot contain Unicode or ANSI multi-byte character sequences.

lpszHeaderValue

A pointer to a string buffer which will contain the header value when the method returns. If this parameter is NULL, the header value will not be copied and the method will return the length. If the buffer is not large enough to contain the entire header value, it will be truncated.

nMaxLength

An integer which specifies the maximum number of characters which can be copied into the *lpszHeaderValue* string buffer. If *lpszHeaderValue* is NULL, this value should be zero. The maximum length must include room for the terminating null character.

Return Value

If the method succeeds, the return value is the length of the header value in characters, not including the terminating null character. If the header is undefined or the method fails, the return value is zero. To get extended error information, call **GetLastError**. If the header field does not exist, the error code will be `ST_ERROR_HEADER_NOT_FOUND`.

Remarks

The **GetHeader** method returns the value of a response header from the last request made to the service provider.

This method is intended for applications that need lower-level access to provider-specific response headers. Most applications do not need to call this method. Standard response information, such as the HTTP status code, response text, token usage, model name, and elapsed time, is available through the API.

The headers returned by a service provider can vary depending on the provider, model, endpoint, account configuration, and the specific request being made. Applications should not assume that a particular header will always be present unless it is documented by the service provider.

If the header field specified by *lpszHeaderName* was not returned by the server, this method will return zero. If the *lpszHeaderValue* parameter is not NULL, it will contain an empty string when the method returns. The response headers are only available after a request has been sent to the server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

ResetSession, SendMessage, SetHeader

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CLlmClient::GetHistorySize Method

```
LONG GetHistorySize();
```

The **GetHistorySize** method returns the maximum number of message exchanges that can be stored in the conversation history.

Parameters

None.

Return Value

If the method succeeds, the return value is the maximum size of the conversation history for the client session. If the method fails, the return value is LLM_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetHistorySize** method returns the maximum number of messages which can be stored in the client conversation history. Each message represents a single request submitted to the model and its associated response.

The conversation history is maintained on a per-session basis and reflects the sequence of interactions performed using the client handle. Messages are stored in chronological order, with new messages appended to the end of the history. To retrieve the contents of a specific message and response from the history, use either the **GetMessage** or **GetMessageById** methods.

It is possible to disable the conversation history by calling the **SetHistorySize** method and specifying a maximum history size of zero. In this case, this method will always return zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

See Also

CLlmClient::GetIdleTime Method

```
INT GetIdleTime();
```

The **GetIdleTime** method returns the current idle time for the specified client session.

Parameters

None.

Return Value

If the method succeeds, the return value is the current idle timeout period in seconds. If the method fails, the return value is LLM_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetIdleTime** method returns the current idle timeout period, in seconds, for the specified client session. This value determines how long a connection can remain idle between requests before the library automatically closes and re-establishes the underlying HTTP connection.

Idle time is used to balance performance and reliability. Reusing an existing connection can reduce overhead and improve performance, particularly when multiple requests are made in quick succession. However, connections that remain idle for extended periods may be closed by the server or by intermediate network infrastructure. When the idle time is exceeded, the library will proactively establish a new connection before sending the next request.

This value is distinct from the timeout period and cache time. The timeout period specifies how long the client will wait for a response to a request before failing, while the cache time controls how long certain responses or metadata may be reused without making a new request. The idle time only affects how long an existing connection is retained between requests.

The idle time can be modified using the **SetIdleTime** method. If a value of zero is specified, a new connection is established for each request. In most cases, the default idle time provides a good balance between performance and compatibility.

It is important to note that this setting only affects client-side behavior. Increasing the idle time does not guarantee that a server will keep the connection open for that duration. Many servers will close idle connections after a shorter period of time, in which case the library will automatically reconnect as needed.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

CLlmClient::GetLastError Method

```
DWORD GetLastError();
```

Parameters

None.

Return Value

The return value is the last error code value for the current thread.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call **GetLastError** immediately when a method's return value indicates that an error has occurred. Functions set this value by calling **SetLastError**. The Return Value section of each reference page notes the conditions under which a function sets the last error code.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or LLM_ERROR. Those functions which call **SetLastError** when they succeed are noted on the method reference page.

This method should only be called when a preceding function indicates failure. Calling this method after a successful call may return a value unrelated to the most recent operation.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

CLlmClient::GetMemoryUsage Method

```
BOOL GetMemoryUsage(
   PLARGE_INTEGER lpMemUsage
);

BOOL GetMemoryUsage(
   LONGLONG *lpMemUsage
);
```

The **GetMemoryUsage** method returns the number of bytes of memory allocated for the client session.

Parameters

lpMemUsage

A pointer to a **LARGE_INTEGER** variable which will contain the number of bytes allocated for the client session when the method returns. This parameter cannot be NULL.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetMemoryUsage** method returns an approximate amount of memory currently allocated for the specified client session. This includes the client session structure, dynamically allocated session data, cached model information, and message history retained by the session.

This method is primarily intended for diagnostics, monitoring, and testing. Applications that maintain long-running sessions or retain large message histories can use this method to monitor how much memory is being used by a client session.

The value returned by this method is rounded up to the nearest system page size and should be treated as an estimate of memory usage rather than an exact byte-for-byte allocation total.

The *lpMemUsage* parameter points to a LARGE_INTEGER structure. The memory usage value is returned in the QuadPart member. In languages that support 64-bit integer values directly, it is safe to pass a pointer to a compatible 64-bit integer variable.

The memory usage reported by this method is limited to memory allocated for the specified client session. It does not include memory used internally by the operating system, networking libraries, provider services, or other process-wide resources.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

CLlmClient::GetMessage Method

```
BOOL LlmGetMessage(
   LONG nMessageIndex,
   LPLLM_MESSAGE lpMessage,
   LPLLM_RESPONSE lpResponse
);
```

The **GetMessage** method retrieves a message turn in the client history using an index value.

Parameters

nMessageIndex

An integer value which identifies the message using a zero-based index value. This value cannot be less than zero or greater than the number of messages in the conversation history.

lpMessage

A pointer to an LLM_MESSAGE structure that receives information about the client request. This parameter may be NULL, in which case no message information is returned.

lpResponse

A pointer to an LLM_RESPONSE structure that receives information about the server response. This parameter may be NULL, in which case no response information is returned.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetMessage** method retrieves a message and its corresponding response from the client history using a zero-based index value. The index value of zero refers to the oldest message currently stored in the history.

The message history is managed as a first-in, first-out (FIFO) queue. When the number of messages exceeds the configured history size, older messages are automatically removed. As a result, the index value for a given message may change over time. Applications that need to reliably reference a specific message should use the **GetMessageById** method instead.

If message history has been disabled, the library does not retain previous messages. However, the most recent message and response are still available and may be retrieved using an index value of zero. This also means the data returned in the LLM_MESSAGE and LLM_RESPONSE structures will only remain valid until the next call to **SendMessage**, **SendMessageEx**, or until the session is reset or disconnected. Applications that need to preserve this information should make a copy of the data before issuing another request.

If the *lpMessage* and/or *lpResponse* parameters are specified, their respective structures must be initialized with the *dwSize* member set to the size of the structure before calling this method. This enables the library to validate the structure version and maintain compatibility with future releases.

Either the *lpMessage* or *lpResponse* parameter may be NULL if only one type of information is required. At least one of these parameters must be specified. If both parameters are NULL, the method fails and sets the error code to ST_ERROR_INVALID_PARAMETER.

Example

```
LLM_MESSAGE clientMessage = { sizeof(LLM_MESSAGE) };
LLM_RESPONSE serverResponse = { sizeof(LLM_RESPONSE) };
LONG nMessageIndex = 0;

// If conversation history is enabled, retrieve the most recent message.
// If history is disabled, an index of 0 refers to the most recent
// message and response from the previous request.

LONG nCount = llmClient.GetMessageCount();

if (llmClient.GetHistorySize() > 0 && nCount > 0)
    nMessageIndex = nCount - 1;

if (llmClient.GetMessage(nMessageIndex, &clientMessage, &serverResponse))
{
    _tprintf(_T("\nMessage %u\n"), clientMessage.dwMessageId);
    _tprintf(_T("  Input Tokens:    %u\n"), clientMessage.nInputTokens);
    _tprintf(_T("  Content Length:  %u\n"), clientMessage.nContentLength);
    _tprintf(_T("  Content:         \"%s\"\n"), clientMessage.lpszContent);

    _tprintf(_T("\nResponse %u\n"), serverResponse.dwMessageId);
    _tprintf(_T("  Elapsed:         %u ms\n"), serverResponse.dwElapsed);
    _tprintf(_T("  Output Tokens:   %u\n"), serverResponse.nOutputTokens);
    _tprintf(_T("  Content Length:  %u\n"), serverResponse.nContentLength);
    _tprintf(_T("  Content:         \"%s\"\n"), serverResponse.lpszContent);
    _tprintf(_T("  Response ID:     %s\n"), (serverResponse.lpszResponseId ?
serverResponse.lpszResponseId : _T("None")));
    _tprintf(_T("  Model Name:      %s\n"), (serverResponse.lpszModelName ?
serverResponse.lpszModelName : _T("None")));
    _tprintf(_T("  Status Text:     %s\n"), (serverResponse.lpszStatusText ?
serverResponse.lpszStatusText : _T("None")));
}
else
{
    DWORD dwError = llmClient.GetLastError();
    _tprintf(_T("Unable to retrieve message at index %ld (error 0x%08lX)\n"),
nMessageIndex, dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

GetFirstMessage, GetMessageById, GetNextMessage, SendMessage, SendMessageEx, SetHistorySize, LLM_MESSAGE, LLM_RESPONSE

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CLlmClient::GetMessageById Method

```
BOOL LlmGetMessageById(
   DWORD dwMessageId,
   LPLLM_MESSAGE lpMessage,
   LPLLM_RESPONSE lpResponse
);
```

The **GetMessageById** method retrieves a message turn in the client history based on a numeric identifier.

Parameters

dwMessageId

A numeric value which identifies a specific message and response.

lpMessage

A pointer to an LLM_MESSAGE structure that receives information about the client request. This parameter may be NULL, in which case no message information is returned.

lpResponse

A pointer to an LLM_RESPONSE structure that receives information about the server response. This parameter may be NULL, in which case no response information is returned.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetMessageById** method retrieves a specific message and its associated response from the client session history. This method can be used when an application has stored a message identifier or has obtained one using methods such as **FindMessage**. Message identifiers are returned when sending requests using **SendMessage** or **SendMessageEx**.

If message history has been disabled, the library does not retain previous messages. However, the most recent message and response are still available and may be retrieved specifying its message identifier. This also means the data returned in the LLM_MESSAGE and LLM_RESPONSE structures will only be valid until the next call to **SendMessage**, **SendMessageEx**, or until the session is reset or disconnected. Applications that need to preserve this information should make a copy of the data before issuing another request.

If the *lpMessage* and/or *lpResponse* parameters are specified, their respective structures must be initialized with the *dwSize* member set to the size of the structure before calling this method. This enables the library to validate the structure version and maintain compatibility with future releases.

Either the *lpMessage* or *lpResponse* parameter may be NULL if only one type of information is required. At least one of these parameters must be specified. If both parameters are NULL, the method fails and sets the error code to ST_ERROR_INVALID_PARAMETER.

Message identifiers are session-specific and are guaranteed to be unique only within the client session in which they were created. Applications must not rely on the internal assignment strategy used to generate these identifiers. The only guaranteed behavior is that message identifiers are assigned values which ensure newer messages always receive larger values than older messages.

If the specified message identifier does not match a message currently stored in the client history, the

method fails. This can occur if the message has been removed because the history was cleared or trimmed.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

FindMessage, GetFirstMessage, GetMessage, GetNextMessage, SendMessage, SendMessageEx

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CLlmClient::GetMessageCount Method

```
LONG GetMessageCount();
```

The **GetMessageCount** method returns the current number of messages in the client history.

Parameters

None.

Return Value

If the method succeeds, the return value is the number of messages in the client history. If the method fails, the return value is LLM_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetMessageCount** method returns the number of messages currently stored in the client session history. Each message represents a single request submitted to the model and its associated response.

The conversation history is maintained on a per-session basis and reflects the sequence of interactions performed using the client handle. Messages are stored in chronological order, with new messages appended to the end of the history. To retrieve the contents of a specific message and response from the history, use either the **GetMessage** or **GetMessageById** methods.

It is possible to disable the conversation history by calling the **SetHistorySize** method and specifying a maximum history size of zero. In this case, this method will always return zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

CLlmClient::GetModelContextSize Method

```
LONG GetModelContextSize(
   LPCTSTR lpszModelName
);
```

The **GetModelContextSize** method returns the context size for the specified model.

Parameters

lpszModelName

A pointer to a null-terminated string that specifies the name of the model. This parameter may be NULL or an empty string, in which case the context size is returned for the model selected for the current client session. If a model name is specified, it must be valid for the provider associated with the client session.

Return Value

If the method succeeds, the return value is the context size for the model. If the method fails, the return value is LLM_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetModelContextSize** method returns the maximum number of tokens that can be processed by the specified model in a single request. This value is commonly referred to as the model's context size or context window.

The context size includes both the input provided to the model and the output generated in response. This means that the total number of tokens in a request, including the prompt, conversation history, and generated response, must not exceed this limit.

If the combined number of tokens exceeds the model's context size, the request may be rejected by the provider or the response may be truncated. Applications should take this limit into account when constructing prompts or maintaining long conversation histories.

In general, larger context sizes allow a model to retain more information from previous interactions, but may also increase latency and cost depending on the provider and model being used.

The context size returned by this method should be treated as an approximate limit rather than an absolute value. For some providers, particularly locally hosted models, the effective context size may be configured or adjusted outside of the application. In these cases, the reported value serves as a guideline and may not reflect the exact limit enforced by the model at runtime.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

CLlmClient::GetModelFlags Method

```
BOOL GetModelFlags(
   LPDWORD lpdwFlags
);
```

The **GetModelFlags** method returns the flags associated with the current model.

Parameters

lpdwFlags

A pointer to an unsigned integer which may have one or more bit flags set when the method returns. If there are no capabilities defined for the provider, this value will be set to **LLM_MODEL_FLAG_NONE**. This parameter cannot be NULL and the value does not need to be initialized by the caller.

Name	Description
LLM_MODEL_FLAG_NONE	No model capabilities defined
LLM_MODEL_FLAG_CHAT	Supports conversational text generation
LLM_MODEL_FLAG_SYSTEM_ROLE	Accepts a system role message in the input
LLM_MODEL_FLAG_STREAMING	Supports streaming responses
LLM_MODEL_FLAG_STRUCTURED	Supports structured output (e.g., JSON or schema)
LLM_MODEL_FLAG_VISION	Supports image inputs (multimodal)
LLM_MODEL_FLAG_TOOLS	Supports tool or function calling
LLM_MODEL_FLAG_REASONING	Supports reasoning-oriented generation
LLM_MODEL_FLAG_RESPONSES	Supports the Responses API (unified endpoint)
LLM_MODEL_FLAG_FUNCTIONS	Supports OpenAI-style function calling with schemas
LLM_MODEL_FLAG_AUDIO	Supports audio output (text-to-speech)
LLM_MODEL_FLAG_IMAGE	Supports image generation
LLM_MODEL_FLAG_VIDEO	Supports video generation
LLM_MODEL_FLAG_TRANSCRIPTION	Supports speech-to-text transcription
LLM_MODEL_FLAG_INSTRUCTIONS	Supports a dedicated instruction field outside message lists
LLM_MODEL_FLAG_MAX_COMPLETION_TOKENS	Uses **max_completion_tokens** instead of **max_tokens** in requests
LLM_MODEL_FLAG_INFERRED	Capabilities are inferred rather than explicitly defined

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetModelFlags** method returns a set of bit flags that describe the capabilities supported by the current model associated with the client session. These flags can be used by applications to determine which features are available and adjust behavior accordingly.

Model capabilities may vary between providers and even between models offered by the same provider. Not all providers return complete capability information when enumerating models. In these cases, some flags may be inferred by the library based on the model name and known characteristics of the provider.

Because capability information may be incomplete or inferred, applications should treat these flags as guidance rather than absolute guarantees of behavior. The provider ultimately determines which features are supported and how they are implemented.

The value returned in the ***lpdwFlags*** parameter is a bitmask and may contain multiple flags combined using a bitwise OR operation. If no capabilities are defined or available for the model, the value will be set to `LLM_MODEL_FLAG_NONE`. In practice, most supported models provide at least basic conversational capabilities, so a value of zero is uncommon and typically indicates that capability information is not available or could not be determined.

In some cases, capability information may be incomplete or inferred. If necessary, applications can override the detected capabilities using the **SetModelFlags** method. This can be useful when working with providers or models that require specific options which are not automatically detected. In general, applications should rely on the default capability detection unless a specific compatibility issue is encountered.

Some flags may be reserved for internal use or represent provider-specific capabilities. Applications should not rely on undocumented flag values and should only test for defined LLM_MODEL_FLAG constants.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

See Also

EnumModels, GetModelContextSize, GetModelInfo, GetModelName, SetModelFlags

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CLlmClient::GetModelInfo Method

```
BOOL GetModelInfo(
   LPCTSTR lpszModelName,
   LPLLM_MODEL_INFO lpModelInfo
);
```

The **GetModelInfo** method returns information about a specific model for the current provider.

Parameters

lpszModelName

A pointer to a null-terminated string that specifies the name of the model. This parameter may be NULL or an empty string, in which case information about the current model associated with the client session is returned.

lpModelInfo

A pointer to an LLM_MODEL_INFO structure that receives information about the model. This parameter cannot be NULL. The ***dwSize*** member of the structure must be initialized before calling this method.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetModelInfo** method retrieves detailed information about a model associated with the provider used by the client session. If a model name is specified, it must be valid for the current provider. If no model name is specified, the method returns information about the model currently associated with the session.

The ***lpModelInfo*** parameter must point to an LLM_MODEL_INFO structure whose ***dwSize*** member has been initialized to `sizeof(LLM_MODEL_INFO)`. This enables the library to validate the structure version and maintain compatibility with future releases.

The information returned by this method includes the model identifier, provider, capability flags, status flags, token limits, context size, and optional metadata such as display name, owner, version, and creation date. Not all providers supply complete metadata for every model, and some values may be empty or unspecified.

Model capability and limit information should be treated as descriptive metadata rather than an absolute guarantee of behavior. Providers may change model availability, limits, or capabilities over time, and locally hosted models may allow some values, such as context size, to be configured outside of the application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

CLlmClient::GetNextMessage Method

```
BOOL GetNextMessage(
   LPLLM_MESSAGE lpMessage,
   LPLLM_RESPONSE lpResponse
);
```

The **GetNextMessage** method returns the next available message in the client history.

Parameters

lpMessage

A pointer to an LLM_MESSAGE structure which receives information about the next message in the client history. This parameter may be NULL if the message information is not needed.

lpResponse

A pointer to an LLM_RESPONSE structure which receives information about the response associated with the message. This parameter may be NULL if the response information is not needed.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**. When the last message in the history is reached, the error code will be set to `ST_ERROR_END_OF_MESSAGES`.

Remarks

The **GetNextMessage** method is used to enumerate the messages stored in the client history. Each successful call advances the internal enumeration position and returns information about the next message and, if available, the response associated with that message.

If the *lpMessage* or *lpResponse* parameters are specified, the structures must be initialized before calling this method. The dwSize member must be set to the size of the corresponding structure. This enables the method to validate the structure version and safely return the requested information.

Either *lpMessage* or *lpResponse* may be NULL. This is useful when an application only needs to enumerate the original messages or only needs information about the responses. At least one of these parameters should be specified.

To begin enumerating messages, call **GetFirstMessage** to retrieve the first message in the client history. Subsequent messages can then be retrieved by calling **GetNextMessage** until the method returns zero and the last error code is set to ST_ERROR_END_OF_MESSAGES. This condition indicates the enumeration has completed and should not be treated as a failure.

Example

```
// Enumerate the message history and display message details
LLM_MESSAGE clientMessage = { sizeof(LLM_MESSAGE), 0 };
LLM_RESPONSE serverResponse = { sizeof(LLM_RESPONSE), 0 };

if (llmClient.GetFirstMessage(&clientMessage, &serverResponse))
{
    do
    {
        _tprintf(_T("\nMessage %u\n"), clientMessage.dwMessageId);
        _tprintf(_T("  Input Tokens:    %u\n"), clientMessage.nInputTokens);
        _tprintf(_T("  Content Length:  %u\n"), clientMessage.nContentLength);
        _tprintf(_T("  Content:         \"%s\"\n"), clientMessage.lpszContent);
```

```
        _tprintf(_T("\nResponse %u\n"), serverResponse.dwMessageId);
        _tprintf(_T("  Elapsed:         %u ms\n"), serverResponse.dwElapsed);
        _tprintf(_T("  Output Tokens:   %u\n"), serverResponse.nOutputTokens);
        _tprintf(_T("  Content Length:  %u\n"), serverResponse.nContentLength);
        _tprintf(_T("  Content:         \"%s\"\n"), serverResponse.lpszContent);
        _tprintf(_T("  Response ID:     %s\n"), (serverResponse.lpszResponseId ?
serverResponse.lpszResponseId : _T("None")));
        _tprintf(_T("  Model Name:      %s\n"), (serverResponse.lpszModelName ?
serverResponse.lpszModelName : _T("None")));
        _tprintf(_T("  Status Text:     %s\n"), (serverResponse.lpszStatusText ?
serverResponse.lpszStatusText : _T("None")));
    }
    while (llmClient.GetNextMessage(&clientMessage, &serverResponse));
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

CLlmClient::GetOptions Method

```
BOOL GetOptions(
   LPDWORD lpdwOptions
);
```

The **GetOptions** method returns the current client option flags.

Parameters

lpdwOptions

A pointer to an unsigned integer that will be set to the current client options when the method returns. This parameter cannot be NULL.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetOptions** method returns the current option flags for the client session. The variable specified by the *lpdwOptions* parameter will be initialized to LLM_OPTION_NONE and then updated with the client options before the method returns. The value may contain one or more of the following flags combined with a bitwise OR operation.

Value	Description
LLM_OPTION_NOCACHE	Disables provider and model metadata caching for the client session. When this option is specified, the library will not reuse cached metadata, and provider or model information will be retrieved from the server each time it is required. This may be useful when testing or when current data is required.
LLM_OPTION_KEEPALIVE	Enables persistent HTTP connections using the keep-alive mechanism. When enabled, the underlying HTTP connection may be reused for multiple requests, reducing connection overhead and improving performance. If this option is not specified, the connection may be closed after each request.
LLM_OPTION_PROXY	Specifies that the connection should be made using the current Windows proxy server configuration. If the user does not have a proxy server configuration, this option is ignored. This option is typically used in environments where direct internet access is restricted.
LLM_OPTION_NOUSERAGENT	Prevents the library from sending a User-Agent header with requests to the provider. By default, a User-Agent string is included to identify the client. This option may be used when a provider does not require a User-Agent header.
LLM_OPTION_SECURE	Forces the use of a secure HTTPS connection when communicating with the provider. If the specified base

	URL or provider default would normally use an insecure protocol, it will be upgraded to a secure connection. Connections to providers such as OpenAI, Google and Anthropic will always be secure.

This method can be used in conjunction with **SetOptions** to query and modify client behavior at runtime.

Example

```
DWORD dwProviderId = LLM_PROVIDER_NONE;
TCHAR szBaseUrl[MAX_PATH] = {0};

// Determine the provider ID for the current session and get
// the base URL used for API requests
dwProviderId = llmClient.GetProviderId();

if (dwProviderId == LLM_PROVIDER_NONE)
{
    _tprintf(_T("Unable to get provider ID for this session\n"));
    return;
}

if (llmClient.GetProviderUrl(szBaseUrl, _countof(szBaseUrl)) < 1)
{
    _tprintf(_T("Unable to get provider endpoint for this session\n"));
    return;
}

// Get the current client options
DWORD dwOptions = LLM_OPTION_NONE;

if (!llmCient.GetOptions(&dwOptions))
{
    _tprintf(_T("Unable to get client options for this session\n"));
    return;
}

// Get information about the current provider
LLM_PROVIDER_INFO providerInfo = { sizeof(providerInfo), 0 };

if (!llmClient.GetProviderInfo(dwProviderId, &providerInfo))
{
    _tprintf(_T("Unable to get provider information\n"));
    return;
}

_tprintf(_T("Connected to %s using %s, the connection is %s\n"),
         providerInfo.szDisplayName,
         szBaseUrl,
         ((dwOptions & LLM_OPTION_SECURE) ? _T("secure") : _T("not secure")));
```

GetProviderId, GetProviderInfo, SetOptions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CLlmClient::GetProviderFlags Method

```
BOOL GetProviderFlags(
   DWORD dwProviderId,
   LPDWORD lpdwFlags
);
```

The **GetProviderFlags** method returns the capability flags associated with a provider.

Parameters

dwProviderId

Specifies the service provider. This parameter must be one of the **LLM_PROVIDER** constants. Refer to the providers page for a list of supported providers and their default models.

lpdwFlags

A pointer to an unsigned integer which receives one or more bit flags when the method returns. If there are no capabilities defined for the provider, this value will be set to LLM_PROVIDER_FLAG_NONE. This parameter cannot be NULL and does not need to be initialized by the caller.

Name	Description
LLM_PROVIDER_FLAG_NONE	No provider requirements specified
LLM_PROVIDER_FLAG_REQUIRE_TLS	Requires a secure TLS (HTTPS) connection
LLM_PROVIDER_FLAG_REQUIRE_AUTH	Requires authentication (e.g., API key or token)
LLM_PROVIDER_FLAG_API_VERSION	Requires an explicit API version parameter
LLM_PROVIDER_FLAG_MODEL_LIST	Supports enumerating available models
LLM_PROVIDER_FLAG_MODEL_INFO	Supports retrieving detailed model information

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetProviderFlags** method retrieves the capability flags associated with the specified provider. These flags describe the features and requirements supported by the provider, such as whether authentication is required or if model enumeration is available.

The value returned in ***lpdwFlags*** may contain one or more LLM_PROVIDER_FLAG values combined with a bitwise OR operation. If no capabilities are defined for the provider, the value will be LLM_PROVIDER_FLAG_NONE.

This method does not require an active client session and can be used to query provider capabilities before establishing a connection. This can be useful when determining how to configure a session or which features are available for a given provider.

If ***dwProviderId*** specifies an invalid provider, the method fails and returns zero.

Example

```
DWORD dwFlags = LLM_PROVIDER_FLAG_NONE;
```

```
if (!llmClient.GetProviderFlags(dwProviderId, &dwFlags))
{
    _tprintf(_T("Unable to get provider flags\n"));
    return;
}

if (dwFlags & LLM_PROVIDER_FLAG_REQUIRE_AUTH)
{
    _tprintf(_T("Provider requires authentication\n"));
}

if (dwFlags & LLM_PROVIDER_FLAG_MODEL_LIST)
{
    _tprintf(_T("Provider supports model enumeration\n"));
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

CLlmClient::GetProviderId Method

```
DWORD GetProviderId();

DWORD GetProviderId(
   LPCTSTR lpszProviderName,
   LPCTSTR lpszBaseUrl,
   LPCTSTR lpszModelName
);
```

The **GetProviderId** method returns the current provider ID or one based on a provider name, endpoint URL or model name.

Parameters

lpszProviderName

A null-terminated string which specifies the provider name. This parameter may be NULL if you do not wish to match against a provider name. At least one parameter must be specified. If a provider name is specified, it is given precedence over the other parameters.

lpszBaseUrl

A null-terminated string which specifies an endpoint URL. This parameter may be NULL if you do not wish to match against an endpoint URL. At least one parameter must be specified. An endpoint URL will only be used if the function is unable to determine the provider ID from the *lpszProviderName* parameter. If an endpoint URL is specified, it is given precedence over a model name.

lpszModelName

A null-terminated string which specifies a model name. This parameter may be NULL if you do not wish to match against a model name. At least one parameter must be specified. A model name will only be used if the function is unable to determine the provider ID from the *lpszProviderName* or *lpszBaseUrl* parameters.

Return Value

If the method succeeds, the return value is the provider ID. If the method fails, the return value is LLM_PROVIDER_UNKNOWN. To get extended error information, call **GetLastError**.

Remarks

The **GetProviderId** method can be called in two different ways. If the method is called without any arguments, it will return the provider ID associated with the current client session. This is useful when an application supports multiple providers and needs to adjust its behavior based on the active provider.

Another version of this method attempts to determine the provider ID using the parameters passed to it in order of precedence. If a provider name is specified and recognized, that value is considered authoritative and the remaining parameters are ignored. If the provider name is not recognized, the method will attempt to determine the provider from the endpoint URL. If the provider cannot be determined from the endpoint URL, the method will attempt to infer the provider from the model name.

The method performs normalization on the input values before matching them against known providers. Leading and trailing whitespace is ignored, provider names are matched without regard to case and common variations of provider names are recognized.

When matching against a model name, the method identifies the company or organization most commonly associated with the model family. This may not reflect the actual service endpoint hosting the model. For example, a model hosted by a local inference server or aggregate provider may still be identified as the company who originally created the model.

This method only recognizes well-known providers, endpoint URLs and model families. If the provider cannot be determined, the method will return `LLM_PROVIDER_UNKNOWN` and the last error code will be set to `ST_ERROR_PROVIDER_NOT_FOUND`.

Example

```
// Get the provider ID for the current client session
DWORD dwProviderId = llmClient.GetProviderId();

if (dwProviderId != LLM_PROVIDER_UNKNOWN)
{
    TCHAR szBaseUrl[128] = {0};
    llmClient.GetProviderUrl(szBaseUrl, _countof(szBaseUrl));

    _tprintf(_T("Provider ID: %lu\n"), dwProviderId);
    _tprintf(_T("Base URL: %s\n"), szBaseUrl);
}
else
{
    DWORD dwError = llmClient.GetLastError();
    _tprintf(_T("Unable to get provider information, error 0x%08lx\n"), dwError);
}

// Determine the provider ID using a base endpoint URL
LPCTSTR lpszUrl = _T("https://api.openai.com/v1/")

dwProviderId = llmClient.GetProviderId(NULL, lpszUrl, NULL);

if (dwProviderId != LLM_PROVIDER_UNKNOWN)
{
    TCHAR szName[64] = {0};
    llmClient.GetProviderName(dwProviderId, szName, _countof(szName));

    _tprintf(_T("The provider for %s is %s\n"), lpszUrl, szName);
}
else
{
    DWORD dwError = llmClient.GetLastError();
    _tprintf(_T("Unable to get the provider ID, error 0x%08lx\n"), dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

GetProviderFlags, GetProviderInfo, GetProviderName, GetProviderUrl

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CLlmClient::GetProviderInfo Method

```
BOOL GetProviderInfo(
   DWORD dwProviderId,
   LPLLM_PROVIDER_INFO lpProviderInfo
);
```

The **GetProviderInfo** method returns information about the specified service provider type.

Parameters

dwProviderId

Specifies the service provider. This parameter must be one of the **LLM_PROVIDER** constants. Refer to the providers page for a list of supported providers and their default models.

lpProviderInfo

A pointer to an LLM_PROVIDER_INFO structure which receives information about the specified provider. The dwSize member must be initialized to the size of the structure before calling this method.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetProviderInfo** method returns general information about a provider, including its display name, description, default host name, default model and related configuration values.

The *lpProviderInfo* parameter must point to an LLM_PROVIDER_INFO structure initialized by the caller. The dwSize member must be set to the size of the structure. This enables the method to validate the structure version before returning provider information.

This method does not require an active client session. It can be used to query provider information before creating a session or connecting to a provider.

The information returned by this method describes the provider defaults defined by the library. A client session may use different values if the application overrides the provider, host name, base URL, model name or other session settings.

Example

```
DWORD dwProviderId = LLM_PROVIDER_NONE;
TCHAR szBaseUrl[MAX_PATH] = {0};

// Determine the provider ID for the current session and get
// the base URL used for API requests
dwProviderId = llmClient.GetProviderId(szBaseUrl, _countof(szBaseUrl));

if (dwProviderId == LLM_PROVIDER_NONE)
{
    _tprintf(_T("Unable to get provider ID for this session\n"));
    return;
}

// Get the current client options
DWORD dwOptions = LLM_OPTION_NONE;
```

```
if (!llmClient.GetOptions(&dwOptions))
{
    _tprintf(_T("Unable to get client options for this session\n"));
    return;
}

// Get information about the current provider
LLM_PROVIDER_INFO providerInfo = { sizeof(providerInfo), 0 };

if (!llmClient.GetProviderInfo(dwProviderId, &providerInfo))
{
    _tprintf(_T("Unable to get provider information\n"));
    return;
}

_tprintf(_T("Connected to %s using %s, the connection is %s\n"),
         providerInfo.szDisplayName,
         szBaseUrl,
         ((dwOptions & LLM_OPTION_SECURE) ? _T("secure") : _T("not secure")));
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetProviderFlags, GetProviderId, GetProviderName

CLlmClient::GetProviderName Method

```
INT GetProviderName(
   DWORD dwProviderId,
   LPTSTR lpszProviderName,
   INT nMaxLength
);

INT GetProviderName(
   DWORD dwProviderId,
   CString &strProviderName
);
```

The **GetProviderName** method returns the display name of the specified provider.

Parameters

dwProviderId

Specifies the service provider. This parameter must be one of the **LLM_PROVIDER** constants. Refer to the providers page for a list of supported providers and their default models.

lpszProviderName

A pointer to a string buffer which will contain the display name for the specified provider when the method returns. This parameter cannot be NULL and must be large enough to contain the display name, including the terminating null character. If the buffer is not large enough to contain the entire name, it will be truncated. An alternate version of this method accepts a **CString** object which will contain the provider name when the method returns.

nMaxLength

An integer value which specifies the maximum number of characters which can be copied into the string buffer, including the terminating null character. This parameter cannot be zero and the method will fail if an invalid size is provided by the caller.

Return Value

If the method succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetProviderName** method returns the display name associated with the specified provider. This is a human-readable string which can be used for logging, status messages or user interface display.

This method is a convenience wrapper which returns the provider display name without requiring the caller to retrieve the full provider information structure using **GetProviderInfo**.

If the buffer specified by ***lpszProviderName*** is not large enough to contain the entire provider name, the string will be truncated. The value returned by the method indicates the number of characters copied to the buffer, not including the terminating null character.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

Unicode: Implemented as Unicode and ANSI versions

GetProviderFlags, GetProviderId, GetProviderInfo, GetProviderUrl

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CLlmClient::GetProviderUrl Method

```
INT GetProviderUrl(
   LPCTSTR lpszBaseUrl,
   INT nMaxLength
);

INT GetProviderUrl(
   CString &strBaseUrl
);
```

The **GetProviderUrl** method returns the current endpoint URL used for client requests.

Parameters

lpszBaseUrl

A pointer to a buffer that receives the base URL used by the client session when making requests to the provider. This parameter may be NULL if the base URL is not required. An alternate version of this method accepts a **CString** object which will contain the URL when the method returns.

nMaxLength

The size of the buffer specified by the lpszBaseUrl parameter, in characters. If lpszBaseUrl is NULL, this value should be zero. If a buffer is provided, it must be large enough to store the base URL, including the terminating null character.

Return Value

If the method succeeds, the return value is the length of the base URL, not including the terminating null character. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetProviderUrl** method can be used to determine the base URL path used by the provider associated with the current client session.

The base URL is returned as a null-terminated string. If the buffer is not large enough to receive the entire string, the method fails and sets the error code to ST_ERROR_BUFFER_TOO_SMALL. We recommend a buffer size of at least 256 characters when retrieving the base URL.

To determine the default endpoint URL used by a specific service provider, use the **GetDefaultUrl** method.

Example

```
DWORD dwProviderId = llmClient.GetProviderId();

if (dwProviderId != LLM_PROVIDER_UNKNOWN)
{
    TCHAR szBaseUrl[256] = {0};
    llmClient.GetProviderUrl(szBaseUrl, _countof(szBaseUrl));

    _tprintf(_T("Provider ID: %lu\n"), dwProviderId);
    _tprintf(_T("Base URL: %s\n"), szBaseUrl);
}
else
{
    DWORD dwError = llmClient.GetLastError();
```

```
    _tprintf(_T("Unable to get provider information, error 0x%08lx\n"), dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

CLlmClient::GetSession Method

```
LPLLM_SESSION GetSession();
```

The **GetSession** method returns the session structure allocated for the current instance of the class.

Parameters

None.

Return Value

This method returns a pointer to the LLM_SESSION structure that was allocated for the class instance. If no session structure has been created, it will return NULL.

Remarks

The **GetSession** method returns a pointer to the LLM_SESSION structure allocated by the **CreateSession** method and used by the **ConnectEx** method to establish a connection. An session structure is used when the application requires more precise control over how the connection to the service provider is established and what parameters are used when interacting with the model.

It is important to note that the session created by the **CreateSession** method is owned and managed by the class instance. Although you may use this method to access the structure members, you should not modify them. The memory allocated for the structure will be automatically released when the class destructor is called. You can also call the **DeleteSession** method if you wish to free the structure immediately, although this is not necessary.

If your project is built using the Unicode character set, this method will return a structure where the string members will point to wide (UTF-16) characters. If your project uses the Multi-Byte character set, the string members will point to UTF-8 encoded strings.

If the **CreateSession** method has not been called, this method will return NULL.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

CLlmClient::GetStatusCode Method

```
INT GetStatusCode();
```

The **GetStatusCode** method returns the most recent HTTP status code for a client request.

Parameters

None.

Return Value

If the method succeeds, the return value is the HTTP status code. If the method fails, the return value is LLM_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetStatusCode** method returns the HTTP status code returned by the provider for the most recent request associated with the specified client session. This value reflects the result of the underlying HTTP operation used to communicate with the provider.

HTTP status codes are three-digit numeric values which indicate whether a request was successful or if an error occurred. They may be interpreted using the following general ranges:

Value	Description
100-199	Informational responses. These are rarely used in practice and indicate that the request has been received and processing is continuing.
200-299	Successful responses. The request was successfully processed by the provider. A value of 200 (OK) is typically returned for successful API requests.
300-399	Redirection responses. These indicate that additional action may be required to complete the request. These responses are uncommon when using API endpoints.
400-499	Client errors. The request was invalid or could not be processed by the provider. This may indicate issues such as invalid parameters, missing authentication credentials or rate limiting.
500-599	Server errors. The provider encountered an error while processing the request. These errors are typically transient and may succeed if the request is retried.

This method can be used in conjunction with the return value of a method such as **SendMessage** or **Connect**. The status code may provide additional information about why a request was rejected or processed with an error condition by the provider. For example, if a request fails and the status code is 503, this indicates the service is temporarily unavailable.

HTTP status codes are returned by the provider service and their exact meaning may vary slightly between providers. Some providers may also return additional diagnostic information in the response body which can help identify the specific cause of the error. Here are some common error status codes and what they could mean in the context of the client session:

- **400 Bad Request** - The request was malformed or contained invalid parameters. This usually indicates an internal error in the library where a request was not composed correctly. This could occur if the service provider does not support certain functionality, an invalid option was used, or an incorrect endpoint was specified.
- **401 Unauthorized** - The API key is missing, invalid, or expired. If you are using an environment

variable or Windows credential, check to make sure it is defined and contains the correct value. If you continue to experience this error, check the provider account to ensure the key has not been revoked or replaced.

- **403 Forbidden** - The request was understood, but the provider refused to process it. This can occur if the account does not have permission to use the selected model, endpoint, organization, or project. Verify that the API key has access to the requested resource and that billing or account restrictions are not preventing the request.
- **404 Not Found** - The requested resource could not be found. This commonly indicates an incorrect endpoint URL, deployment name, model name, or provider-specific path. Verify that the provider, base URL, and model name are correct for the account being used.
- **408 Request Timeout** - The provider did not complete the request before the timeout expired. This can occur because of network latency, a temporary service issue, a large prompt, or a model that requires more time to generate a response. Consider increasing the timeout value, reducing the prompt or history size, or retrying the request later.
- **409 Conflict** - The request conflicts with the current state of the service or resource. This is uncommon for simple message requests, but may occur with provider-specific operations, duplicate requests, or incompatible settings. Review the request options and retry the operation after any pending provider-side operation has completed.
- **413 Payload Too Large** - The request body is larger than the provider allows. This usually means the prompt, conversation history, attached content, or generated request JSON exceeds the model or endpoint limit. Reduce the prompt size, clear or shorten the conversation history, or select a model with a larger context size. The **TrimHistory** method can be used to reduce the amount of conversation history included with a prompt.
- **415 Unsupported Media Type** - The provider does not support the request content type or encoding. This can indicate that the request was not submitted as JSON, that the wrong endpoint was used, or that the provider does not support the submitted content format. Verify the endpoint and make sure the request format matches the provider requirements.
- **422 Unprocessable Entity** - The provider accepted the request format, but could not process the request contents. This can occur if a model option, reasoning level, response format, tool definition, or other provider-specific setting is not valid for the selected model. Review the selected model and options, and disable unsupported features.
- **429 Too Many Requests** - The provider rejected the request because a rate limit, usage limit, or account quota was exceeded. Applications should wait before retrying the request, reduce the request rate, and avoid retrying immediately in a tight loop. If the error persists, review the provider account limits, billing status, and usage quotas.
- **500 Internal Server Error** - The provider encountered an unexpected server-side error while processing the request. This usually indicates a temporary problem with the provider rather than the application. Retry the request later, and check the provider status page if the problem continues.
- **502 Bad Gateway** - A gateway or proxy received an invalid response from an upstream service. This is typically a temporary provider-side or network condition. Retry the request after a short delay, and check whether the provider is experiencing a service disruption.
- **503 Service Unavailable** - The service is temporarily unavailable because of maintenance,

overload, or resource limits. Retry the request after a delay. If the provider returns a retry interval, the application should wait at least that long before trying again.

- **504 Gateway Timeout** - A gateway or proxy timed out waiting for an upstream service to complete the request. This can occur when the provider is under heavy load or when a response takes too long to generate. Retry the request later, reduce the prompt size, or request a shorter response.

If no request has been made, or if the client has not yet received a response from the provider, the return value may be zero. If the client handle is invalid or a request is currently in progress, the method will return LLM_ERROR (-1). In this case, a status code is not available.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

CLlmClient::GetSystemPrompt Method

```
INT GetSystemPrompt(
   LPTSTR lpszSystemPrompt,
   INT nMaxLength
);

INT GetSystemPrompt(
   CString &strSystemPrompt
);
```

The **GetSystemPrompt** method returns the current system prompt for a client session.

Parameters

lpszSystemPrompt

A pointer to a string buffer which receives the system prompt for the current session. If this parameter is NULL, the method returns the length of the system prompt without copying any characters. If a buffer is provided, it must be large enough to contain the entire prompt, including the terminating null character, or the method will fail. An alternate version of this method accepts a **CString** object which will contain the system prompt when the method returns.

nMaxLength

An integer value which specifies the maximum number of characters which can be copied into the string buffer, including the terminating null character. If the ***lpszSystemPrompt*** parameter is NULL, this value should be zero.

Return Value

If the method succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetSystemPrompt** method retrieves the system prompt associated with the specified client session. The system prompt provides initial instructions to the model and influences how responses are generated for subsequent requests.

To retrieve the system prompt, an application can first call this method with a NULL buffer to determine the required length, then allocate a buffer of sufficient size and call the method again to retrieve the prompt.

If a system prompt has not been defined for the session, the method returns zero and the last error code is set to NO_ERROR. This condition indicates that no prompt is currently set and should not be treated as a failure.

The system prompt may be specified when creating a session using **ConnectEx** and the LLM_SESSION structure, or modified at runtime using **SetSystemPrompt**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CLlmClient::GetTimeout Method

```
INT GetTimeout();
```

The **GetTimeout** method returns the number of seconds the client will wait for a response from the server.

Parameters

None.

Return Value

If the method succeeds, the return value is the timeout period in seconds. If the method fails, the return value is LLM_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetTimeout** method returns the current timeout value for the specified client session. This value specifies the maximum amount of time, in seconds, that the client will wait for a response from the provider before the request is aborted.

The timeout applies to network operations performed when communicating with the provider. If the timeout period is exceeded, the request will fail and the last error code will indicate a timeout condition.

The timeout value may be specified when creating a session using **ConnectEx** and the LLM_SESSION structure, or modified at runtime using **SetTimeout**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

CLlmClient::GetTokenUsage Method

```
BOOL GetTokenUsage(
   LPLLM_TOKEN_USAGE lpUsage
);
```

The **GetTokenUsage** method returns token usage statistics for the client session.

Parameters

lpUsage

A pointer to an LLM_TOKEN_USAGE structure which receives token usage statistics for the client session. The dwSize member must be initialized to the size of the structure before calling this method.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetTokenUsage** method returns token usage statistics for the specified client session. This information includes token counts reported by the provider, as well as values maintained by the library for the current conversation history.

The ***lpUsage*** parameter must point to an LLM_TOKEN_USAGE structure initialized by the caller. The dwSize member must be set to the size of the structure. This enables the method to validate the structure version before returning usage information.

Token usage values are intended to help applications monitor request size, response size and context usage. The exact values reported may vary by provider and model, and should be treated as informational rather than as a guarantee of billing or model behavior.

This method returns the usage information currently associated with the client session. The values are updated as messages are sent and responses are received.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CLlmClient::GetUserAgent Method

```
INT GetUserAgent(
   LPTSTR lpszUserAgent,
   INT nMaxLength
);
```

The **GetUserAgent** method returns the current user-agent string used by the client.

Parameters

lpszUserAgent

A pointer to a string buffer which receives the user-agent string for the current session. If this parameter is NULL, the method returns the length of the user-agent string without copying any characters. If a buffer is provided, it must be large enough to contain the entire string, including the terminating null character, or the method will fail.

nMaxLength

An integer value which specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. If the ***lpszUserAgent*** parameter is NULL, this value should be zero.

Return Value

If the method succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetUserAgent** method retrieves the user-agent string currently configured for the client session. This value is included in HTTP requests sent to the provider unless disabled using the LLM_OPTION_NOUSERAGENT option.

If no user-agent string has been explicitly set using **SetUserAgent**, the method may return a default value defined by the library, or no value depending on the current configuration.

To determine the required buffer size, call this method with ***lpszUserAgent*** set to NULL. The return value specifies the number of characters in the string, excluding the terminating null character. If there is no user-agent string defined for the session, the method returns zero and the last error value is cleared (set to NO_ERROR). This condition should not be treated as a failure.

In most cases, the user-agent string will be relatively small. A buffer of 256 characters is typically sufficient for standard user-agent values. If a custom user-agent string is used, a larger buffer (such as 512 characters) may be more appropriate. Applications that require complete flexibility should query the required length and allocate the buffer dynamically.

The user-agent string is typically used by providers for logging or request identification. Developers should avoid including sensitive information in this value.

Example

```
TCHAR szUserAgent[256] = _T("");

if (llmClient.GetUserAgent(szUserAgent, _countof(szUserAgent)) > 0)
{
    _tprintf(_T("User-Agent: %s\n"), szUserAgent);
```

```
}
else
{
    DWORD dwError = llmClient.GetLastError();
    _tprintf(_T("Error retrieving user-agent (0x%08lX)\n"), dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CLlmClient::ImportHistory Method

```
BOOL ImportHistory(
   LPCTSTR lpszFileName,
   LONG nMessageCount,
   LPLONG lpnImported
);

BOOL ImportHistory(
   LPCTSTR lpszFileName,
   LPLONG lpnImported
);
```

The **ImportHistory** method imports a conversation history from a JSON-formatted file.

Parameters

lpszFileName

A pointer to a null-terminated string which specifies the name of the import file. This parameter cannot be NULL or a zero-length string.

nMessageCount

The number of the most recent messages and responses which should be imported. If this value is zero, all messages in the file are imported.

lpnImported

A pointer to an integer which will receive the number of messages which were imported when the method returns. If this information is not required, this parameter may be NULL.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **ImportHistory** method imports a previously exported conversation history file and restores it as the active conversation history for the client session. Imported messages and responses become part of the current session history and are treated the same as messages generated during the current session.

Importing conversation history replaces the existing history associated with the client session. This method does not merge imported messages with the current conversation history or append them to the existing session. It is not necessary for your application to call **ClearHistory** prior to calling this method.

If the *lpszFileName* parameter specifies a directory or device name, the method will fail. It is permitted to use environment variables in the file name by surrounding the variable name with the percent symbol. If the file name contains any leading or trailing space characters, they will be removed. The file must exist and the current process must have permission to read the file.

If the *nMessageCount* parameter is non-zero, only the most recent messages and responses in the import file are restored. If the specified count exceeds the number of available messages in the file, all available messages are imported. If the total number of messages to be imported exceeds the current history size, the method will only import the most recent messages up to that limit. For example, if the import file contains 20 messages and the current history size is 15, the most recent 15 messages will be imported.

The import file must contain valid UTF-8 encoded JSON data in a format compatible with the **ExportHistory** method. If the file does not appear to contain a valid conversation history, the import operation fails before the current session history is cleared.

After the JSON data has been successfully parsed, the current session history is cleared before the imported messages and responses are added to the client session. If an error occurs while processing imported messages or responses, the previous conversation history cannot be restored and partial import data may remain in the current session.

If the import file contains malformed message or response data, the **GetLastError** method will return `ST_ERROR_INVALID_MESSAGE_FORMAT`.

Because imported history files may contain sensitive or private information, applications should take reasonable precautions to protect them. Applications which allow users to import conversation history should consider warning users before importing untrusted or unknown files.

Example

```
LONG nImported = 0;

// Replace the current conversation history with the
// messages stored in the import file
if (llmClient.ImportHistory(
                    _T("%USERPROFILE%\\Documents\\conversation.json"),
                    &nImported))
{
    _tprintf(_T("Imported %ld messages\n"), nImported);
}
else
{
    DWORD dwError = llmClient.GetLastError();
    _tprintf(_T("Unable to import conversation history, error 0x%08lX\n"),
dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

CLlmClient::IsBlocking Method

```
BOOL IsBlocking();
```

The **IsBlocking** method is used to determine if the client is currently performing a blocking operation.

Parameters

None.

Return Value

If the client is performing a blocking operation, the method returns a non-zero value. If the client is not performing a blocking operation, or the client handle is invalid, the method returns zero. To get extended error information, call **GetLastError**.

Remarks

A blocking operation may allow the application to be re-entered. For example, the user may press a button while another request is still in progress. If this causes another blocking method to be called for the same client session, the second operation will fail because only one blocking operation can be active at a time.

The **IsBlocking** method can be used to determine if the client is already blocked, and if so, take some other action, such as warning the user that they must wait for the current operation to complete.

When a message is sent to the server using the **SendMessage** or **SendMessageEx** methods, the client will block until the message is sent and the server has responded, or until a timeout has occurred. If you send a request to the server in your application's main UI thread, you should present some visual indicator that the application is waiting for the operation to complete. If you need to ensure your application remains responsive while waiting for a response from the server, you can send messages using a background worker thread.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

See Also

Cancel, IsConnected, SendMessage, SendMessageEx, SetTimeout

CLlmClient::IsConnected Method

```
BOOL IsConnected();
```

The **IsConnected** method verifies that the client session remains valid.

Parameters

None.

Return Value

If the client session is valid and connected to a server, the method returns a non-zero value. If the client is not connected, the method returns zero. To get extended error information, call **GetLastError**.

Remarks

The **IsConnected** method determines whether there is a logical connection to the service provider and the client has successfully authenticated with the API server. Calling this method is not simply a passive status check. The network connection to the provider may be transient and can be automatically re-established if the client session has been idle. Calling **IsConnected** may cause the library to reconnect and re-authenticate with the server if necessary.

If the client must re-authenticate, it will attempt to reconnect to the server and validate the selected model for the session. If the server reports an error condition, such as an invalid API key, the connection will not be re-established and the method will return zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

CLlmClient::IsInitialized Method

```
BOOL IsInitialized();
```

The **IsInitialized** method returns whether or not the class object has been successfully initialized.

Parameters

None.

Return Value

This method returns a non-zero value if the class object has been successfully initialized. A return value of zero indicates that the runtime license key could not be validated or the networking library could not be loaded by the current process.

Remarks

When an instance of the class is created, the class constructor will attempt to initialize the component with the runtime license key that was created when SocketTools was installed. If the constructor is unable to validate the license key or load the networking libraries, this initialization will fail.

If SocketTools was installed with an evaluation license, the application cannot be redistributed to another system. The class object will fail to initialize if the application is executed on another system, or if the evaluation period has expired. To redistribute your application, you must purchase a development license which will include the runtime key that is needed to redistribute your software to other systems. Refer to the Developer's Guide for more information.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

CLlmClient::NormalizeText Method

```
INT NormalizeText(
   LPCTSTR lpszInput,
   INT cchInput,
   LPTSTR lpszOutput,
   INT nMaxLength
);

INT NormalizeText(
   LPCTSTR lpszInput,
   CString &strOutput
);
```

The **NormalizeText** method normalizes message text by removing extraneous whitespace and applying consistent formatting.

Parameters

lpszInput

A pointer to a null-terminated string which specifies the text which should be normalized. This parameter cannot be NULL.

cchInput

An integer which specifies the length of the input string. If this value is -1 the entire input string up to the terminating null character will be normalized.

lpszOutput

A pointer to a string buffer which will contain the normalized text when the method returns. The output string will always be null-terminated. If the string buffer is not large enough to contain all of the normalized text, the method will fail and the last error code will be set to `ST_ERROR_BUFFER_TOO_SMALL`. An alternate version of this method accepts a **CString** object which will contain the normalized text when the method returns.

nMaxLength

An integer which specifies the maximum number of characters which can be copied into the output string buffer. This value must be large enough to include a terminating null character. If this value is too small, or an invalid length is specified, the method will fail.

Return Value

If the method succeeds, the return value is the number of characters copied to the output buffer, not including the terminating null character. If the method fails, the return value is zero and the **GetLastError** method will return a non-zero value.

Remarks

The **NormalizeText** method processes the input string, decomposing Unicode characters to their canonical equivalents, replacing confusable homoglyphs with normalized characters, removing combining characters, normalizing end-of-line characters, and trimming leading and trailing whitespace including non-breaking spaces and other special Unicode space characters. Although removing unnecessary whitespace may slightly reduce token usage, the primary benefit is producing cleaner and more consistent input for the model to process.

Line break characters are normalized to use Windows end-of-line conventions. Isolated carriage return or line feed characters, Unicode line and paragraph separators, and form feed characters are

converted to CRLF sequences. Multiple consecutive line breaks are reduced to improve consistency.

Normalization can be useful when comparing prompts, checking for empty or whitespace-only input, or applying simple validation rules before a request is submitted. It does not attempt to determine whether the text is safe, appropriate, or semantically valid. Applications should perform any additional validation required for their own use case.

Using this method is optional. Prompt text does not need to be normalized before it is sent to a provider, and using this method is not a required sanitization step. If preserving the exact formatting of the original text is important, such as indentation, tables, or code samples, the application should send the original text instead.

The ANSI version of this method expects the input to be UTF-8 encoded, but will fall back to using the current locale if invalid UTF-8 characters are encountered in the string. The output from this function will always be valid Unicode text. For applications using the ANSI version of this method, this means the output string will use UTF-8 encoding.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

CLlmClient::ResetSession Method

```
BOOL ResetSession();
```

The **ResetSession** method resets the current client session to its initial state, clearing any existing conversation context.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **ResetSession** method resets the client session to its initial state. Any active connection to the service provider is closed, the conversation history is cleared, and token usage statistics for the session are reset.

This method can be used to discard the current conversation context and start a new session using the existing client handle. Configuration settings such as the selected provider, model name, system prompt, and client options are preserved.

If a blocking operation is currently in progress, this method will fail. Applications should call **IsBlocking** to determine if the client is busy before attempting to reset the session.

Because this method clears the conversation history, it also invalidates any string pointers previously returned in LLM_RESPONSE structures or by message history methods. Applications must not use those pointers after this method returns. If the application needs to keep any message or response text, it should make its own copy before resetting the session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

CLlmClient::SendMessage Method

```
BOOL SendMessage(
   LPCTSTR lpszPrompt,
   LPTSTR lpszResponse,
   LPDWORD lpdwLength,
   LPDWORD lpdwMessageId
);
```

The **SendMessage** method sends a prompt to the model and returns the response as a string.

Parameters

lpszPrompt

A pointer to a null-terminated string which specifies the message prompt which should be sent to the model. This parameter cannot be NULL or a zero-length string. If the string consists only of whitespace characters, or contains invalid Unicode or non-text data, this method will fail.

lpszResponse

A pointer to a string buffer which will contain the model's response to the prompt. The response will always be null terminated and if the buffer is not large enough to store the complete response, the response will be truncated. The ***lpdwLength*** parameter must be initialized with the maximum number of characters which can be copied into the buffer or the method will fail.

lpdwLength

A pointer to an unsigned integer which should be initialized to the size of the ***lpszResponse*** string buffer. When the method returns, this value will be updated with the actual number of characters copied into the buffer, not including the terminating null character. This parameter cannot be NULL and its initial value must be greater than zero.

lpdwMessageId

A pointer to an unsigned integer which will contain the ID for the message when the method returns. This parameter may be NULL if the application does not require the message ID.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **SendMessage** method provides a simplified interface for sending a single text prompt to the model and receiving the response as a string. This method is intended for applications that do not require structured input or detailed control over message formatting.

This method will not return until the request has completed, an error has occurred, or the operation has timed out. Applications that call this method from a user interface thread should provide visual feedback while waiting for the response, or perform the request on a background thread to maintain responsiveness.

Applications that accept user input should apply appropriate validation, filtering, or normalization before sending requests to the service provider. The **ValidateText** method verifies that the prompt contains valid message text and the **NormalizeText** method can be used to normalize text formatting. These functions do not perform any semantic analysis of the prompt and do not provide protection against malicious or intentionally misleading input.

This method does not validate or restrict the content of the input message. It is the responsibility of the application to ensure that user-provided input is appropriate for its intended use. This includes considering scenarios where input may attempt to override instructions, inject unintended prompts, or otherwise influence the behavior of the model.

The response is written to the buffer specified by ***lpszResponse***. If the buffer is not large enough to contain the complete response, the text will be truncated. The ***lpdwLength*** parameter will always contain the number of characters actually copied to the buffer.

Line breaks in the response text are normalized before being stored in the client history. Line feed and carriage return characters are converted to the standard Windows CRLF end-of-line sequence, ensuring consistent formatting across different providers and applications. This also helps ensure compatibility with Windows common controls and other user interface components.

Some models are capable of performing additional internal reasoning before generating a response. The amount of reasoning performed and whether it is exposed by the provider is model-specific. The library returns the final response intended for the user and does not currently expose model reasoning or intermediate processing steps. This behavior ensures consistent results across providers, regardless of how individual models implement or expose reasoning capabilities.

If the ***lpdwMessageId*** parameter is specified, it will receive a unique identifier for the message within the current client session. Message identifiers are assigned sequentially, but applications should treat them as opaque values. They are only guaranteed to be unique within a single session and should not be compared across different client sessions.

This method automatically adds the message to the conversation history for the session. Subsequent calls will include previous messages as context, subject to any configured history or token limits. To clear the conversation context, call **ClearHistory** or **ResetSession**.

Applications that require more advanced features, such as structured messages, role-based input, or access to detailed response metadata, should use the **SendMessageEx** method instead.

Example

```
#include "cstools12.h"
#include <stdio.h>

int _tmain(void)
{
    CLlmClient llmClient;

    // Establish a connection to OpenAI using the default endpoint
    // and a lightweight model
    BOOL bConnected = llmClient.Connect(
        LLM_PROVIDER_OPENAI,
        LLM_OPTION_DEFAULT,
        LLM_TIMEOUT,
        NULL,                   // Use default base URL
        _T("gpt-5.4-nano"),     // Model name
        _T("%OPENAI_API_KEY%")  // Provider API key
    );

    if (!bConnected)
    {
        dwError = llmClient.GetLastError();
        _tprintf(_T("Unable to connect, error %lu\n"), dwError);
        return 1;
    }
```

```
    TCHAR szResponse[4096] = {0};
    DWORD dwResponseLength = _countof(szResponse); // number of TCHARs
    DWORD dwMessageId = 0;

    // Send a simple message to the model
    if (llmClient.SendMessage(
                    _T("What is the capital city of Denmark?"),
                    szResponse,
                    &dwResponseLength,
                    &dwMessageId))
    {
        _tprintf(_T("Response:\n%s\n"), szResponse);
    }
    else
    {
        dwError = llmClient.GetLastError();
        _tprintf(_T("Request failed, error %lu\n"), dwError);
    }

    // Close the connection explicitly
    llmClient.Disconnect();
    return 0;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CLlmClient::SendMessageEx Method

```
BOOL SendMessageEx(
   LPLLM_MESSAGE lpMessage,
   LPLLM_RESPONSE lpResponse
);
```

The **SendMessageEx** method sends a structured message to the model and returns a structured response.

Parameters

lpMessage

A pointer to a LLM_MESSAGE structure which specifies the message to be sent to the server. This parameter cannot be NULL. The structure must be initialized correctly, with the ***dwSize*** member set to the size of the structure. Unused members of the structure should be initialized to zero or NULL.

lpResponse

A pointer to a LLM_RESPONSE structure which will be populated with information about the response from the server when the method returns. This parameter cannot be NULL. The structure must be initialized correctly, with the ***dwSize*** member set to the size of the structure and all other members set to a value of zero or NULL.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **SendMessageEx** method provides the structured form of **SendMessage**. It should be used by applications that need to specify additional message properties, inspect detailed response metadata, or preserve information such as response identifiers, token usage, status values, elapsed time, and the actual model name returned by the provider.

This method performs a blocking operation. It will not return until the request has completed, an error has occurred, or the operation has timed out. Applications that call this method from a user interface thread should provide visual feedback while waiting for the response, or perform the request on a background thread to maintain responsiveness.

The ***lpMessage*** and ***lpResponse*** structures must be initialized before calling this method. At a minimum, the ***dwSize*** member of each structure must be set to the size of the structure, and all unused members should be initialized to zero or NULL.

If a message identifier is returned in the response structure, it is unique within the current client session. Message identifiers are assigned sequentially by the library, but applications should treat them as opaque values. They are not guaranteed to be globally unique across multiple sessions or between different clients.

This method automatically adds the message and response to the conversation history for the session. Subsequent calls may include previous messages as context, subject to any configured history or token limits. To clear the conversation context, call **ClearHistory** or **ResetSession**.

Applications that accept user input should apply appropriate validation, filtering, or normalization before sending requests to the service provider. The **ValidateText** method verifies that the prompt contains valid message text and the **NormalizeText** method can be used to normalize text

formatting. These methods do not perform any semantic analysis of the prompt and do not provide protection against malicious or intentionally misleading input.

Line breaks in the response text are normalized before being stored in the client history. Line feed and carriage return characters are converted to the standard Windows CRLF end-of-line sequence, ensuring consistent formatting across different providers and applications. This also helps ensure compatibility with Windows common controls and other user interface components.

Some models are capable of performing additional internal reasoning before generating a response. The amount of reasoning performed and whether it is exposed by the provider is model-specific. The library returns the final response intended for the user and does not currently expose model reasoning or intermediate processing steps. This behavior ensures consistent results across providers, regardless of how individual models implement or expose reasoning capabilities.

The string members of the LLM_MESSAGE and LLM_RESPONSE structures are managed by the library. When a message is sent, any string pointers provided in the LLM_MESSAGE structure are copied internally, and the application is not required to preserve or maintain those buffers after the method returns.

String pointers returned in the LLM_RESPONSE structure refer to memory managed by the client session. These values remain valid until the message history is cleared or the session is reset or disconnected. Applications should not attempt to free or modify these strings.

The contents of these strings must be treated as read-only. They are owned by the library, and modifying them may result in access violations or other undefined behavior. If your application needs to retain a string beyond the lifetime of the session or modify its contents, it should create its own copy.

Example

```
#include "cstools12.h"
#include <stdio.h>

int _tmain(void)
{
    CLlmClient llmClient;

    // Establish a connection to OpenAI using the default endpoint
    // and a lightweight model
    BOOL bConnected = llmClient.Connect(
        LLM_PROVIDER_OPENAI,
        LLM_OPTION_DEFAULT,
        LLM_TIMEOUT,
        NULL,                   // Use default base URL
        _T("gpt-5.4-nano"),     // Model name
        _T("%OPENAI_API_KEY%")  // Provider API key
    );

    if (!bConnected)
    {
        DWORD dwError = LlmGetLastError();
        _tprintf(_T("Unable to connect, error %lu\n"), dwError);
        return 1;
    }

    LLM_MESSAGE clientMessage;
    ZeroMemory(&clientMessage, sizeof(LLM_MESSAGE));
    clientMessage.dwSize = sizeof(clientMessage);
```

```
    clientMessage.lpszContent = _T("What is the capital city of Denmark?");
    clientMessage.nContentLength = _tcslen(clientMessage.lpszContent);

    LLM_RESPONSE serverResponse;
    ZeroMemory(&serverResponse, sizeof(serverResponse));
    serverResponse.dwSize = sizeof(serverResponse);

    if (llmClient.SendMessageEx(&clientMessage, &serverResponse))
    {
        _tprintf(_T("Flags: 0x%08lX\n"), serverResponse.dwFlags);
        _tprintf(_T("Status: %u\n"), serverResponse.dwStatus);
        _tprintf(_T("Elapsed: %u ms\n"), serverResponse.dwElapsed);
        _tprintf(_T("Output Tokens: %u\n"), serverResponse.nOutputTokens);
        _tprintf(_T("Content Length: %u\n"), serverResponse.nContentLength);
        _tprintf(_T("Response ID: %s\n"), (serverResponse.lpszResponseId ?
serverResponse.lpszResponseId : _T("None")));
        _tprintf(_T("Model Name: %s\n"), (serverResponse.lpszModelName ?
serverResponse.lpszModelName : _T("None")));
        _tprintf(_T("Status Text: %s\n"), (serverResponse.lpszStatusText ?
serverResponse.lpszStatusText : _T("None")));

        if (serverResponse.nContentLength > 0)
            _tprintf(_T("\n%s\n"), serverResponse.lpszContent);
    }
    else
    {
        dwError = LlmGetLastError();
        _tprintf(_T("Request failed, error %lu\n"), dwError);
    }

    // Close the connection explicitly
    llmClient.Disconnect();
    return 0;
}
```

Requirements

CLlmClient::SetCacheTime Method

```
BOOL SetCacheTime(
   INT nCacheTime
);
```

The **SetCacheTime** method sets the cache lifetime used by the client for model or provider data.

Parameters

nCacheTime

An integer value which specifies the cache lifetime, in seconds, for provider and model metadata. A value of zero disables caching and forces the client to retrieve this information from the server for each request. Larger values reduce network requests but may result in stale information being used.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **SetCacheTime** method controls how long the client caches provider and model metadata. This includes information such as the list of available models and details about the currently selected model.

Caching reduces the number of network requests required when retrieving model lists or model information, which can improve performance and reduce latency. However, because model availability and capabilities may change over time, cached data may become stale if it is retained for extended periods.

Changing this value will have no effect if the LLM_OPTION_NOCACHE option has been specified.

Setting the cache time to zero disables caching and is equivalent to specifying the LLM_OPTION_NOCACHE option. Note that this differs from specifying a cache time of zero in the LLM_SESSION structure during initialization, where a value of zero indicates that a default cache lifetime will be used.

The cache time is specified in seconds. If a value greater than or equal to 1000 is specified, it is assumed that the value may have been provided in milliseconds, and it will be automatically scaled to seconds. The specified cache time is clamped to an internal minimum and maximum value if it falls outside the supported range. The default cache time is one hour.

In most cases, the default cache time provides a good balance between performance and accuracy. Applications that frequently query model information or require real-time updates may choose to reduce or disable caching.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

CLlmClient::SetHeader Method

```
BOOL SetHeader(
   LPCTSTR lpszHeaderName,
   LPTSTR lpszHeaderValue
);
```

The **SetHeader** method sets the value of a custom HTTP header issued with subsequent requests.

Parameters

hClient

A handle to the client session.

lpszHeaderName

A pointer to a null-terminated string which specifies the name of the HTTP header field. Header names may only contain ASCII letters, numbers and a restricted subset of punctuation characters. Header names cannot contain Unicode or ANSI multi-byte character sequences.

lpszHeaderValue

A pointer to a null-terminated string which specifies the value of the HTTP header. Header values cannot contain carriage-return or linefeed characters. If the value contains Unicode characters, they will be UTF-8 encoded. If this parameter or NULL or a zero-length string, the header field is deleted from the request headers.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**. If the header name contains illegal characters or cannot be changed (e.g., attempting to change the `Authorization` header), the method will return zero and the last error code will be set to `ST_ERROR_INVALID_HEADER_NAME`. If the header value contains illegal characters, the last error code will be set to `ST_ERROR_INVALID_HEADER_VALUE`.

Remarks

The **SetHeader** method assigns a custom HTTP request header that will be included with subsequent requests made using the current client session. If the specified header already exists in the custom header list, its value will be replaced. If the header value is an empty string, the header will be removed.

This method is intended for advanced applications that require lower-level access to provider-specific functionality. Most applications should not need to use custom request headers. Some headers are managed internally by the library and cannot be overridden using this method. This includes headers required for authentication, content formatting, message length, host identification, and other protocol-specific functionality required by the current provider.

Examples of headers that are managed internally by the library include:

- `Authorization`
- `Content-Length`
- `Content-Type`
- `Host`
- `User-Agent`

Custom headers remain associated with the current client session until they are removed using the

ClearHeaders method, the **ResetSession** method is called, or the connection is closed using the **Disconnect** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

CLlmClient::SetHistorySize Method

```
BOOL SetHistorySize(
   LONG nMaxMessages
);
```

The **SetHistorySize** method sets the maximum number of message exchanges retained in the conversation history.

Parameters

nMaxMessages

An integer value which specifies the maximum number of messages that will be retained in the conversation history for the client session. Older messages will be discarded automatically as new messages are added once this limit is reached. This value cannot be less than zero.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **SetHistorySize** method controls the number of messages retained in the conversation history for a client session. This history is used to provide context for subsequent requests to the model.

When the number of messages exceeds the specified limit, the oldest messages are removed automatically. This ensures that the total number of stored messages does not exceed the configured maximum.

Reducing the history size can help limit memory usage and reduce the amount of context sent with each request, which may improve performance and reduce token usage. However, limiting the history size may also reduce the model's ability to maintain context across multiple interactions.

This setting works in conjunction with token limits imposed by the selected model. Even if the maximum number of messages has not been reached, older messages may be excluded from a request if including them would exceed the model's context window.

If ***nMaxMessages*** has a value of zero, conversation history is effectively disabled. In this mode, only the current message and response are retained for the duration of the request, and no prior messages are included as context for subsequent requests. Disabling conversation history may reduce the model's ability to maintain context across multiple interactions and can impact the quality or relevance of responses. Methods such as **GetFirstMessage** and **GetNextMessage** will fail with the last error code set to ST_ERROR_NO_MESSAGE_HISTORY.

Disabling conversation history does not provide additional security or privacy. It only affects whether previous messages are retained and automatically included in subsequent requests. The content of each request is still transmitted to the service provider and may be processed or stored in accordance with that provider's policies. Applications that require secure handling of sensitive information should avoid including confidential data in requests and review the data handling practices of the selected service provider.

Even when message history is disabled, the model may still produce responses that appear contextually relevant within a single interaction. This is because the current request can include sufficient context for the model to generate an appropriate response. However, without retaining previous messages, the model does not have access to prior exchanges in the conversation, and

continuity across multiple requests may be limited. In most cases, retaining a moderate history size provides better results for conversational applications.

The default history size is 100 message exchanges.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

CLlmClient::SetIdleTime Method

```
BOOL LlmSetIdleTime(
   INT nIdleTime
);
```

The **SetIdleTime** method sets the idle timeout period for the client session.

Parameters

nIdleTime

An integer value which specifies the idle timeout period in seconds. A value of zero specifies a reasonable default value should be used.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **SetIdleTime** method sets the idle timeout period, in seconds, for the specified client session. This value determines how long the library will retain an open connection between requests before automatically closing it and establishing a new connection when needed.

Setting a lower idle time may result in more frequent reconnections, which can increase overhead but may be desirable in environments where connections are short-lived. Higher values allow connections to be reused for longer periods, which can improve performance when making repeated requests.

Changing this value is only meaningful when the LLM_OPTION_KEEPALIVE option is enabled. If keep-alive is disabled for the session, the connection will not be reused regardless of the idle time setting. If the *nIdleTime* parameter is set to zero, a new connection is established for each request. In most cases, a default idle time of 15 seconds provides a good balance between performance and compatibility.

This setting applies only to the client. It cannot force a server to maintain a persistent connection for a longer period of time. If a connection is closed due to inactivity, the library will automatically reconnect as needed. This behavior is transparent to the application and does not require any additional method calls.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

CLlmClient::SetLastError Method

```
VOID SetLastError(
   DWORD dwErrorCode
);
```

The **SetLastError** method sets the last error code for the current thread.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or LLM_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

Applications can retrieve the value saved by this method by using the **GetLastError** method. The use of **GetLastError** is optional; an application can call the method to determine the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

See Also

CLlmClient::SetModelFlags Method

```
BOOL SetModelFlags(
   DWORD dwModelFlags
);
```

The **SetModelFlags** method sets model behavior flags for a client session.

Parameters

dwModelFlags

An unsigned integer which specifies one or more capability flags for the selected model. This value cannot be zero.

Name	Description
LLM_MODEL_FLAG_CHAT	Supports conversational text generation
LLM_MODEL_FLAG_SYSTEM_ROLE	Accepts a system role message in the input
LLM_MODEL_FLAG_STREAMING	Supports streaming responses
LLM_MODEL_FLAG_STRUCTURED	Supports structured output (e.g., JSON or schema)
LLM_MODEL_FLAG_VISION	Supports image inputs (multimodal)
LLM_MODEL_FLAG_TOOLS	Supports tool or function calling
LLM_MODEL_FLAG_REASONING	Supports reasoning-oriented generation
LLM_MODEL_FLAG_RESPONSES	Supports the Responses API (unified endpoint)
LLM_MODEL_FLAG_FUNCTIONS	Supports OpenAI-style function calling with schemas
LLM_MODEL_FLAG_AUDIO	Supports audio output (text-to-speech)
LLM_MODEL_FLAG_IMAGE	Supports image generation
LLM_MODEL_FLAG_VIDEO	Supports video generation
LLM_MODEL_FLAG_TRANSCRIPTION	Supports speech-to-text transcription
LLM_MODEL_FLAG_INSTRUCTIONS	Supports a dedicated instruction field outside message lists
LLM_MODEL_FLAG_MAX_COMPLETION_TOKENS	Uses `max_completion_tokens` instead of `max_tokens` in requests

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **SetModelFlags** method overrides the capability flags associated with the currently selected model. These flags determine how the client formats requests and interprets responses for the model.

Model capability flags are normally determined automatically by the library based on the selected provider and model. This method is primarily intended for advanced scenarios where the default behavior must be adjusted, such as when working with custom providers, locally hosted models, or when a model's capabilities have changed and are not yet reflected in the library.

The specified flags must include **LLM_MODEL_FLAG_CHAT**, as the API requires a chat-based interface for sending and receiving messages. Specifying flags that are not supported by the selected model may result in request failures or undefined behavior.

Changing model flags can affect how requests are constructed, such as which parameters are used, how input is formatted, and which features are enabled. Applications should only modify these flags if they fully understand the capabilities of the target model.

If you enable a capability that is not supported by the model or provider, this will often result in an error condition and may cause subsequent requests to fail. For example, if you attempt to force the use of a system prompt by setting the LLM_MODEL_FLAG_SYSTEM_ROLE flag, this can cause unexpected failures on models hosted locally using an application like LM Studio.

Changing the current model using the **SetModelName** method will reset the model flags for the session back to their default values for the new model.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

CLlmClient::SetOptions Method

```
BOOL SetOptions(
   DWORD dwOptions
);
```

The **SetOptions** method changes the current client option flags.

Parameters

dwOptions

An unsigned integer that specifies one or more options.

Value	Description
LLM_OPTION_NOCACHE	Disables provider and model metadata caching for the client session. When this option is specified, the library will not reuse cached metadata, and provider or model information will be retrieved from the server each time it is required. This may be useful when testing or when current data is required.
LLM_OPTION_KEEPALIVE	Enables persistent HTTP connections using the keep-alive mechanism. When enabled, the underlying HTTP connection may be reused for multiple requests, reducing connection overhead and improving performance. If this option is not specified, the connection may be closed after each request.
LLM_OPTION_PROXY	Specifies that the connection should be made using the current Windows proxy server configuration. If the user does not have a proxy server configuration, this option is ignored. This option is typically used in environments where direct internet access is restricted.
LLM_OPTION_NOUSERAGENT	Prevents the library from sending a User-Agent header with requests to the provider. By default, a User-Agent string is included to identify the client. This option may be used when a provider does not require a User-Agent header.
LLM_OPTION_SECURE	Forces the use of a secure HTTPS connection when communicating with the provider. If the specified base URL or provider default would normally use an insecure protocol, it will be upgraded to a secure connection. Connections to providers such as OpenAI, Google and Anthropic will always be secure.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **SetOptions** method replaces the current option flags for the client session. These flags control

how the client establishes connections and sends requests to the service provider.

Applications should use care when changing options that affect the underlying connection, such as LLM_OPTION_SECURE or LLM_OPTION_PROXY. Changing these options may require the client to establish a new connection using different settings.

The LLM_OPTION_SECURE option forces the client to use HTTPS when communicating with the provider. This is appropriate for public API providers, but may not be supported by locally hosted providers such as LM Studio or Ollama. Attempting to force a secure connection to a provider that does not support HTTPS will cause the connection to fail.

The LLM_OPTION_PROXY option causes the client to use the configured proxy settings when connecting to the provider. This may be required in managed or corporate network environments, but should not be enabled unless proxy support is actually needed.

The LLM_OPTION_NOUSERAGENT option does not make requests anonymous. The provider may still identify the client based on authentication credentials, IP address information, request patterns, or other HTTP headers included with the request. For more information, refer to the **SetUserAgent** method.

Setting or clearing the LLM_OPTION_NOCACHE option changes whether provider and model metadata may be cached. Applications can also use the **SetCacheTime** method to control caching behavior in seconds.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

CLlmClient::SetSystemPrompt Method

```
BOOL SetSystemPrompt(
   LPCTSTR lpszSystemPrompt
);
```

The **SetSystemPrompt** method changes the current system prompt for a client session.

Parameters

hClient

A handle to the client session.

lpszSystemPrompt

A pointer to a string buffer which will contain the new system prompt for the current session. If this parameter is NULL or an empty string, a system prompt will not be included with new requests.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

A system prompt provides instructions that are included with each request sent to the model. It can be used to define the expected role, tone, response style, formatting rules, or other application-specific guidance that should apply to the session.

For example, an application might use a system prompt to request short responses, avoid Markdown formatting, return structured text, or answer only within the context of a specific feature or workflow.

Because conversation history is included with each request, messages that were generated using a previous system prompt may still influence subsequent responses. Changing or clearing the system prompt does not retroactively modify existing messages in the history. If the new prompt represents a significant change in behavior, applications may want to clear the history to avoid unintended interactions between the previous and current instructions.

If the new prompt represents a significant change in behavior, applications may want to call **ClearHistory** before sending additional messages.

The system prompt should be treated as guidance, not a guarantee. Different providers and models may interpret system instructions differently, and user messages may still influence the response. If ***lpszSystemPrompt*** is NULL or points to an empty string, the current system prompt is cleared and no system prompt will be included with new requests.

Support for system prompts may vary between providers and models. Some providers treat the system prompt as a distinct message role, while others incorporate it as part of a separate instruction field. The library will map the system prompt to the appropriate format for the selected provider, but the exact behavior and influence on the response may differ. Applications should test system prompt behavior with their selected provider to ensure it produces the desired results.

Note that some providers or models will not provide any support for a system role. This is more common with locally hosted models using applications like LM Studio or Ollama. To determine if a model supports system prompts, use the **GetModelFlags** method and check for the LLM_MODEL_FLAG_SYSTEM_ROLE flag.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

CLlmClient::SetTimeout Method

```
BOOL SetTimeout(
   UINT nTimeout
);
```

The **SetTimeout** method sets the number of seconds the client will wait for a blocking operation to complete.

Parameters

nTimeout

The number of seconds to wait for a blocking operation to complete.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **SetTimeout** method sets the timeout period, in seconds, for blocking operations such as sending a message to the server. If a request does not complete within the specified time, the operation will fail and return a timeout error.

The minimum timeout period is 5 seconds and the maximum timeout period is 300 seconds. If a value outside this range is specified, it will be clamped to the nearest supported value. Specifying a value of zero resets the timeout to the default value of 60 seconds.

The appropriate timeout value may vary depending on the selected provider, model, and network conditions. Larger or more complex models may require additional time to generate a response. Locally hosted models may also require longer timeouts depending on the available hardware resources, such as CPU or GPU performance.

The maximum timeout period is intended to prevent applications from waiting indefinitely for a response. If an operation consistently requires several minutes to complete, applications should consider performing the request on a background thread or using a smaller or faster model.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

CLlmClient::SetUserAgent Method

```
BOOL SetUserAgent(
   LPCTSTR lpszUserAgent
);
```

The **SetUserAgent** method changes the current user-agent string used by the client.

Parameters

lpszUserAgent

A pointer to a string buffer which will contain the new user-agent string for the current session. If this parameter is NULL or a zero-length string, the method will reset the user-agent string to a default value.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **SetUserAgent** method changes the user-agent string used by the client session. The specified string is trimmed to remove leading and trailing whitespace and will be used the next time the client establishes a connection to the provider.

If *lpszUserAgent* is NULL or points to an empty string, the current user-agent string is cleared and a new default value is generated for the session.

The default user-agent string uses a format similar to Chromium-based browsers and includes information about the current Windows platform and the SocketTools version. If an application name was specified when the session was created, it may also be included in the default value.

For example, a default user-agent string may look similar to the following:

```
Mozilla/5.0 (Windows NT 10.0; Win64; x64) Chrome/134.0.0.0 Safari/537.36
SocketTools/12.0
```

Applications normally do not need to change the user-agent string. However, a custom value may be useful when an application needs to identify itself to a provider, gateway, proxy, or logging system.

Developers should avoid including sensitive information, such as API keys, account identifiers, or user-specific data, in the user-agent string.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

CLlmClient::ShowError Method

```
INT ShowError(
   LPCTSTR lpszAppTitle,
   UINT uType,
   DWORD dwErrorCode
);
```

The **ShowError** method displays a message box which describes the specified error.

Parameters

lpszAppTitle

A null-terminated string which specifies the title of the message box that is displayed. If this argument is NULL or omitted, then the default title of "Error" will be displayed.

uType

An unsigned integer which specifies the type of message box that will be displayed. This is the same value that is used by the **MessageBox** method in the Windows API. If a value of zero is specified, then a message box with a single OK button will be displayed. Refer to that function for a complete list of options.

dwErrorCode

Specifies the error code that will be used when displaying the message box. If this argument is zero, then the last error that occurred in the current thread will be displayed.

Return Value

If the method is successful, the return value will be the return value from the **MessageBox** method. If the method fails, it will return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

CLlmClient::TrimHistory Method

```
LONG TrimHistory(
   LONG nMessageCount,
   LONG nMaxTokens
);
```

The **TrimHistory** method removes older messages from the conversation history for the current client session.

Parameters

nMessageCount

The number of messages to remove from the beginning of the conversation history. If this value is zero, messages are only removed if required by the ***nMaxTokens*** parameter. If this value is equal to or greater than the number of messages in the history, the entire history is cleared.

nMaxTokens

The maximum number of input tokens that should remain in the conversation history. If this value is zero, token usage is not checked. If the current history exceeds this value, additional older messages may be deleted until the total input token count is below the specified limit.

Return Value

If the method succeeds, the return value is the number of messages deleted from the conversation history. If the method fails, the return value is LLM_ERROR. To get extended error information, call **GetLastError**.

If no messages are available to delete, the return value is zero.

Remarks

The **TrimHistory** method removes messages from the beginning of the conversation history. This can be used to reduce memory usage, discard older context, or limit how much previous conversation text is included with future requests.

The ***nMessageCount*** parameter specifies the minimum number of older messages to remove. If ***nMaxTokens*** is greater than zero, the method also checks the total number of input tokens currently stored in the message history. If the token count exceeds the specified limit, additional older messages will be removed until the total input token count is below the specified threshold.

When both parameters are specified, the method may remove more messages than requested by ***nMessageCount*** to reduce the token count below the limit specified by ***nMaxTokens***. The return value always indicates the actual number of messages removed.

If the number of messages to remove is equal to or greater than the number of messages currently stored, the entire conversation history is cleared. This is equivalent to calling **ClearHistory**.

This method only removes the local message and response history maintained by the client session. It does not change the current provider, model, system prompt, connection settings or cached provider metadata.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

Import Library: csllmv12.lib

CLlmClient::ValidateModel Method

```
BOOL ValidateModel(
   LPCTSTR lpszModelName
);
```

The **ValidateModel** method validates that a model name is recognized or supported by the current provider.

Parameters

lpszModelName

A null-terminated string which specifies the name of the model to validate. This parameter cannot be NULL or a zero-length string.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **ValidateModel** method verifies that a model name appears to be valid for the current session. Validation may be performed using locally available information or by querying the provider for a list of supported models. If the provider supports returning model information, this method may perform a lookup to confirm that the specified model name is recognized. This may require a network request and can cause the method to block while the model list is retrieved.

If the provider does not support returning model information, the method only performs basic validation of the model name. For example, it will check the name to ensure it does not contain any illegal characters and uses a format that is common for most service providers. This method is most commonly used with applications to validate user input.

A successful return value from this method only indicates that the model name is syntactically valid. It does not guarantee that the selected service provider will accept or allow the model to be used. A provider may reject a valid model name for several reasons, including the model being unavailable for the current account, restricted to specific subscription tiers, region-limited, deprecated, disabled by administrative policy, or not supported by the endpoint being used. Providers may also change model availability over time without notice. Applications should be prepared to handle errors returned when establishing a session or sending a request, even if the model name was validated successfully.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CLlmClient::ValidateText Method

```
BOOL ValidateText(
   LPCTSTR lpszMessageText,
   INT cchMessageText
);
```

The **ValidateText** method performs basic validation on text before it is submitted to a model.

Parameters

lpszMessageText

A pointer to the message text to validate. This parameter cannot be NULL.

cchMessageText

The number of characters in the message text, excluding the terminating null character. If this parameter is omitted or the value is -1, the text must be null-terminated and the entire string is checked.

Return Value

If the message text appears to be valid, the method returns non-zero. If the message text is empty, contains invalid characters, or appears to contain non-text data, the method returns zero. To get extended error information, call **GetLastError**.

Remarks

The **ValidateText** method is intended to help applications detect invalid or malformed input before sending a request to a model. It checks for common problems such as empty strings, text that consists only of spaces or line breaks, illegal Unicode code points, non-printable characters, and input that appears to contain binary data. The message text cannot contain embedded null characters.

Applications that accept messages from users or other external sources should validate the text before submitting it to a model. This can help detect malformed or invalid input before a request is sent, reducing the chance of unexpected results or incurring unnecessary usage costs.

This method does not evaluate the quality, safety, or semantic meaning of the message. Although this method is most commonly used to check prompts sent to a model, it can be used to validate any type of text to ensure it is not malformed and contains printable characters.

If your project uses the Unicode character set, this method validates the text as UTF-16 Unicode. If your project uses the Multi-Byte character set, it attempts to interpret the input as UTF-8 encoded text. If the input is not valid UTF-8, it attempts to convert the text to Unicode using the active code page and the resulting Unicode text is validated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

Large Language Model Data Structures

- LLM_MESSAGE
- LLM_MODEL_INFO
- LLM_PROVIDER_INFO
- LLM_RESPONSE
- LLM_SESSION
- LLM_TOKEN_USAGE

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

LLM_MESSAGE

The **LLM_MESSAGE** structure represents a message sent from the client to the LLM server.

```
typedef struct _LLM_MESSAGE
{
    DWORD   dwSize;
    DWORD   dwRoleId;
    DWORD   dwFlags;
    DWORD   dwReasoningLevel;
    DWORD   dwMessageId;
    DWORD   dwReserved;
    TIME_T  tTimestamp;
    LONG    nMaxTokens;
    LONG    nInputTokens;
    LONG    nContentLength;
    LPCTSTR lpszContent;
} LLM_MESSAGE, *LPLLM_MESSAGE;
```

Members

dwSize

The size of this structure, in bytes. This member must be set to `sizeof(LLM_MESSAGE)` before the structure is used.

dwRoleId

The role associated with the message, such as user, assistant or system. This member should be one of the following values:

Constant	Description
LLM_ROLE_UNKNOWN	Unknown or invalid role. This value is typically used when a message has not been initialized correctly or could not be classified.
LLM_ROLE_USER	A message originating from the end-user. This is the most common role and represents input provided by the application or user interface.
LLM_ROLE_ASSISTANT	A response generated by the language model. Messages with this role are typically returned by the library as part of the conversation history.
LLM_ROLE_SYSTEM	A system-level instruction that defines how the model should behave. This is typically used to set context, tone, or constraints for the session before user messages are processed.
LLM_ROLE_FUNCTION	A legacy role used for method call messages in older APIs. This role is retained for compatibility but is generally not used in new implementations.
LLM_ROLE_TOOL	A message generated by an external tool or method invoked by the model. This role is used when integrating tool or method-calling workflows.
LLM_ROLE_TOOLUSER	A user message that is specifically intended for processing by a tool or method, rather than direct model interpretation.

LLM_ROLE_DEFAULT	The default role assigned to messages. This is equivalent to LLM_ROLE_USER.

dwFlags

A value reserved for future use. This member should always be set to zero or `LLM_MESSAGE_FLAG_NONE`.

dwReasoningLevel

The reasoning effort level associated with the message. This member may be set to one of the `LLM_REASONING` constants to control how much reasoning the model should apply when generating a response. A value of `LLM_REASONING_DEFAULT` uses the provider or model default behavior.

dwMessageId

An identifier assigned to the message. For application-supplied input messages, this value is initially zero. When a message has been added to a session or returned from the message history, this member may contain a unique identifier assigned by the library.

dwReserved

A reserved value for future use. This member should always be zero.

tTimestamp

The timestamp associated with the message. For application-supplied input messages, this value is typically zero. When available, this member contains the time the message was created.

nMaxTokens

The maximum number of output tokens associated with the message. This value is primarily used when submitting a request and may be zero to indicate the session or provider default should be used.

nInputTokens

The number of input tokens associated with the message content. This value is typically provided by the library when token usage information is available.

nContentLength

The length of the message content, in characters, not including the terminating null character. If this value is zero, the content length may be determined from the string.

lpszContent

A pointer to a null-terminated string which contains the message text. This member may be NULL if the message consists only of media content.

Remarks

This structure is used to describe a single message in a conversation with a language model. Messages are typically assigned a role using one of the constants, such as `LLM_ROLE_USER` for user input, `LLM_ROLE_ASSISTANT` for a model response, or `LLM_ROLE_SYSTEM` for an instruction message that defines the behavior of the session. In most applications, those roles are required. Other roles are used for advanced scenarios such as tool integration or legacy compatibility.

The **LLM_MESSAGE** structure is used for both input and output operations. When passed to methods such as **SendMessageEx**, it defines a message that will be submitted to the language model. In this case, the application typically initializes only the required members, such as ***dwSize***, ***dwRoleId***, and the content or media fields. When used with methods such as **GetFirstMessage** and **GetNextMessage**, this structure is populated by the library to return messages from the current session history. In this case, additional members such as the message identifier, timestamp, and token counts may contain

values assigned by the library. Applications should treat values returned by the library as read-only unless otherwise documented.

The *lpszContent* member specifies the text associated with the message. For the ANSI version of this structure, this string must be UTF-8 encoded. In the Unicode version, the string is specified as UTF-16 using a wide character pointer.

The *nContentLength* member specifies the content length in characters rather than bytes. If this value is zero, the library may determine the length from the null-terminated string. Applications should not assume that token counts are identical to character counts. The *nInputTokens* member, when available, reflects the tokenized size of the message content as determined by the model or provider.

The *dwReasoningLevel* member controls the reasoning effort requested for the message. Higher reasoning levels may improve the quality, accuracy, or depth of responses, particularly when using reasoning-capable models, but they can also increase response time and token usage costs. Lower reasoning levels generally favor faster responses and reduced usage costs. Not all providers or models support configurable reasoning levels, and unsupported values may be ignored by the provider. If this member is set to `LLM_REASONING_DEFAULT`, the library will use the default reasoning behavior for the current provider or model.

The *tTimestamp* member is a standard 64-bit Unix time value and can be used interchangeably with functions in the C standard library such as **gmtime** or **localtime**. Because it is a 64-bit integer, it is not impacted by the Year 2038 problem. Timestamps can be converted into a local date and time using the **ConvertTimestamp** method.

Unless otherwise noted, any reserved members should be set to zero before calling a method which accepts this structure. Applications should also avoid modifying structure members that are returned by the library unless the documentation for a specific method indicates that doing so is supported.

The *lpszContent* member of this structure is managed by the library. Applications should treat this value as read-only and must not attempt to modify the contents of the string. If the application needs to retain or modify this data, it should create its own copy.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

LLM_MODEL_INFO

The **LLM_MODEL_INFO** structure contains descriptive information and capability data for a language model.

```
typedef struct _LLM_MODEL_INFO
{
    DWORD    dwSize;
    DWORD    dwProviderId;
    DWORD    dwFlags;
    DWORD    dwStatus;
    DWORD    dwReserved;
    LONG     nMaxTokens;
    LONG     nContextSize;
    FLOAT    fTemperature;
    FLOAT    fMaxTemperature;
    FILETIME ftCreated;
    TCHAR    szName[LLM_MODEL_NAMELEN];
    TCHAR    szDisplayName[LLM_MODEL_NAMELEN];
    TCHAR    szOwner[LLM_MODEL_NAMELEN];
    TCHAR    szVersion[LLM_MODEL_VERLEN];
    TCHAR    szCreated[LLM_MODEL_DATELEN];
} LLM_MODEL_INFO, *LPLLM_MODEL_INFO;
```

Members

dwSize

The size of this structure, in bytes. This member must be set to `sizeof(LLM_MODEL_INFO)` before the structure is used.

dwProviderId

The provider associated with the model. This member should be one of the LLM_PROVIDER values.

dwFlags

One or more capability flags associated with the model. This member may contain a combination of LLM_MODEL_FLAG values.

dwStatus

One or more status flags associated with the model. This member may contain a combination of LLM_MODEL_STATUS values.

dwReserved

A reserved value for future use. This member should always be zero.

nMaxTokens

The maximum number of tokens the model can generate in response to a request. A value of zero indicates that this limit is not specified.

nContextSize

The maximum context window size for the model, in tokens. If this value is zero, the context size is unspecified or the provider does not distinguish it from ***nMaxTokens***.

fTemperature

The default temperature value associated with the model. A value of zero may indicate that the value is not specified.

fMaxTemperature

The maximum supported temperature value for the model. A value of zero indicates that this limit is not specified.

ftCreated

The creation date and time associated with the model, expressed as a FILETIME value. If this member is zero, the creation time is not available.

szName

A null-terminated string which specifies the model identifier used by the provider, such as `gpt-5` or `claude-4-sonnet`.

szDisplayName

A null-terminated string which specifies an optional display name for the model. This value is intended for presentation to the user and may be an empty string.

szOwner

A null-terminated string which specifies the optional owner, vendor, or organization associated with the model. This value may be an empty string.

szVersion

A null-terminated string which specifies the optional version identifier associated with the model. If this information is not available, the value will be an empty string.

szCreated

A null-terminated string which specifies the optional model creation date in text form. If this information is not available, the value will be an empty string.

Remarks

This structure is used to return information about a model that is available through a specific provider. It is typically populated by the library when enumerating models or retrieving detailed information about a specific model. Applications should treat the contents of this structure as descriptive metadata and should not assume that every member will contain a meaningful value for every model.

The ***dwProviderId*** member identifies which service or platform supplies the model, using one of the `LLM_PROVIDER` constants. The ***dwFlags*** member describes the capabilities supported by the model, such as conversational input, structured output, reasoning, vision, tool calling, or audio support. The ***dwStatus*** member indicates the current state of the model, such as whether it is generally available, in preview, or deprecated. These values are defined by the library using the `LLM_MODEL_FLAG` and `LLM_MODEL_STATUS` constants.

The ***nMaxTokens*** value represents the maximum output token limit reported for the model. This limit only applies to generated content and may be lower than the model's total context window. The client can further restrict the length of generated responses if necessary. If this value is zero, it means the provider does not publish information about the maximum number of output tokens supported for a response. Internally, providers often impose generation limits that are lower than the total context size for a request, even if those limits are not publicly documented.

The ***nContextSize*** value represents the maximum number of tokens the model can process in a single request, including the system prompt, conversation history, user messages and generated output. Most cloud-based service providers offer models which support very large context windows while limiting the maximum number of tokens that can be generated in a single response. For example, a model may support a context window of 1,000,000 tokens, allowing it to process very large conversations or documents, while limiting individual responses to 128,000 output tokens.

The context window and maximum token values are advisory. They are used when the service

provider does not return detailed limit information for a model. These values should be treated as general guidance and are not enforced by the library. The actual limits may vary depending on the provider, model version, deployment, enabled features and account limits. A value of zero for either ***nMaxTokens*** or ***nContextSize*** means those limits cannot be determined for the model. For locally hosted models or cloud-based aggregators, these limits may also be configurable for a specific model.

The metadata strings are provided for identification and display purposes. The ***szName*** member contains the canonical model name used in API requests, while ***szDisplayName*** provides a more user-friendly label when one is available. Other fields, such as ***szOwner***, ***szVersion***, ***szCreated***, and ***ftCreated***, are optional and may not be supplied by every provider.

Applications should set the ***dwSize*** member before passing this structure to a method. Unless otherwise documented, reserved members should be set to zero. When this structure is returned by the library, string members are stored directly in the fixed-length buffers contained within the structure, and may be read safely by the application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

LLM_PROVIDER_INFO

The **LLM_PROVIDER_INFO** structure provides descriptive information and default connection settings for a language model provider.

```
typedef struct _LLM_PROVIDER_INFO
{
    DWORD   dwSize;
    DWORD   dwProviderId;
    DWORD   dwFlags;
    DWORD   dwReserved;
    LONG    nProtocol;
    LONG    nHostPort;
    TCHAR   szName[LLM_PROVIDER_NAMELEN];
    TCHAR   szHostName[LLM_PROVIDER_HOSTLEN];
    TCHAR   szDefaultModel[LLM_MODEL_NAMELEN];
} LLM_PROVIDER_INFO, *LPLLM_PROVIDER_INFO;
```

Members

dwSize

The size of this structure, in bytes. This member must be set to `sizeof(LLM_PROVIDER_INFO)` before the structure is used.

dwProviderId

The provider identifier. This member should be one of the `LLM_PROVIDER` values. Refer to the providers page for a list of supported providers and their default models.

dwFlags

One or more provider capability flags. This member may contain a combination of `LLM_PROVIDER_FLAG` values.

dwReserved

A reserved value for future use. This member should always be zero.

nProtocol

The protocol used by the provider endpoint. Most cloud-based service providers require secure connections and applications should use `LLM_PROTOCOL_HTTPS`. For locally hosted models running on the same system or over a local network, `LLM_PROTOCOL_HTTP` can be used to establish a standard, non-secure connection.

nHostPort

The network port number associated with the provider endpoint. A value of zero indicates that the provider-specific default port should be used.

szName

A null-terminated string which specifies a canonical provider name, such as `"OpenAI"`. This value may be used for identification or display in the user interface.

szHostName

A null-terminated string which specifies the default host name or IP address for the provider endpoint. This value may be an empty string for custom or application-defined providers.

szDefaultModel

A null-terminated string which specifies the default model name associated with the provider. This value may be an empty string if the provider requires the application to explicitly specify a model

name.

Remarks

This structure is used to describe a language model provider, including its identity, endpoint information, and basic capabilities. It is typically populated by the library when enumerating known providers or retrieving information about a specific provider.

The ***dwProviderId*** member identifies the provider using one of the `LLM_PROVIDER` constants, while the ***dwFlags*** member indicates provider-level requirements or supported features, such as whether the provider requires TLS, requires authentication, supports enumerating models, or supports returning detailed model information. The ***nProtocol*** member identifies the default protocol used to communicate with the provider endpoint, such as HTTP or HTTPS.

The string members provide descriptive metadata about the provider. The ***szName*** member contains the canonical provider name. The ***szHostName*** member specifies the default network hostname associated with the provider, and ***szDefaultModel*** specifies the default model that may be used if the application does not explicitly choose one.

Not all providers supply the same level of detail. Some values may be empty or unspecified, particularly for custom, local, or application-defined providers. Applications should treat the contents of this structure as descriptive metadata and should not assume that every member will contain a meaningful value in all cases.

Applications should set the ***dwSize*** member before passing this structure to a method. Unless otherwise documented, reserved members should be set to zero. Because all string values are stored directly in the fixed-length buffers contained within the structure, the application may safely read or copy them as needed.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

LLM_RESPONSE

The **LLM_RESPONSE** structure represents the response returned by a language model.

```
typedef struct _LLM_RESPONSE
{
    DWORD   dwSize;
    DWORD   dwRoleId;
    DWORD   dwFlags;
    DWORD   dwMessageId;
    DWORD   dwStatus;
    DWORD   dwElapsed;
    DWORD   dwReserved;
    TIME_T  tTimestamp;
    LONG    nOutputTokens;
    LONG    nContentLength;
    LPCTSTR lpszResponseId;
    LPCTSTR lpszModelName;
    LPCTSTR lpszStatusText;
    LPCTSTR lpszContent;
} LLM_RESPONSE, *LPLLM_RESPONSE;
```

Members

dwSize

The size of this structure, in bytes. This member must be set to `sizeof(LLM_RESPONSE)` before the structure is used.

dwRoleId

The role associated with the response. This member will typically be set to `LLM_ROLE_ASSISTANT`, but may vary depending on the type of response returned.

dwFlags

Response flags. This member is reserved for future use and should typically be set to `LLM_RESPONSE_FLAG_NONE`.

dwMessageId

The identifier of the originating request message. This value corresponds to the *dwMessageId* member of the **LLM_MESSAGE** structure that initiated the request.

dwStatus

The response status code. This member should be one of the `LLM_RESPONSE values`, indicating how the request completed.

dwElapsed

The elapsed time, in milliseconds, required to process the request and generate the response.

dwReserved

A reserved value for future use. This member should always be zero.

tTimestamp

A 64-bit integer timestamp associated with the response. This member specifies when the response was received and the value is represented as the number of seconds from January 1, 1970 UTC.

nOutputTokens

The number of tokens generated by the response. This value is provided when token usage information is available.

nContentLength

The length of the response content, in characters, not including the terminating null character.

lpszResponseId

A null-terminated string which specifies a provider-defined identifier for the response. This value may be NULL.

lpszModelName

A null-terminated string which specifies the name of the model used to generate the response. This value may be NULL.

lpszStatusText

A null-terminated string which specifies a provider-specific status or diagnostic message. This value may be NULL.

lpszContent

A null-terminated string which specifies the response text returned by the model.

Remarks

The LLM_RESPONSE structure represents the result of a request submitted to a language model. It is typically returned by methods such as **SendMessageEx** and provides both the generated response content and additional metadata describing how the request was processed.

This structure is logically paired with the **LLM_MESSAGE** structure. While the **LLM_MESSAGE** structure defines the input provided to the model, the **LLM_RESPONSE** structure contains the output generated by the model along with status and diagnostic information. The ***dwMessageId*** member may be used to associate the response with the originating request message.

The ***lpszContent*** member points to a null-terminated string buffer which contains the response from the model. The ***nContentLength*** member specifies how many characters are in the response, not including the terminating null character. Line feed and carriage return characters are converted to the standard Windows CRLF end-of-line sequence, ensuring consistent formatting across different providers and applications. This also helps ensure compatibility with Windows common controls and other user interface components.

The ANSI version of this structure uses UTF-8 encoded strings, while the Unicode version uses UTF-16 encoded strings. Response text returned by a provider may contain Unicode characters, including international text, typographical symbols, emoji, mathematical symbols, or other non-ASCII characters. Applications should ensure that any user interface controls, files, or other components used to display or process response text are capable of handling Unicode text correctly.

Applications which cannot process Unicode text in the response can provide a system prompt requesting that the model limit its output to ASCII characters. However, because model output is non-deterministic, applications should not assume that non-ASCII characters will never be returned.

The ***dwStatus*** member indicates how the request completed. A value of `LLM_RESPONSE_COMPLETE` indicates that the response was generated normally, while other values may indicate that the response was truncated due to token limits, cancelled, timed out, or failed due to an error. Applications should always check this value before processing the response content.

The ***dwElapsed*** member provides the total time required to process the request, which can be useful for performance monitoring or diagnostics. The ***nOutputTokens*** member, when available, indicates the number of tokens generated by the model, which may be useful for usage tracking or cost estimation.

The ***tTimestamp*** member is a standard 64-bit Unix time value which indicates when the response was

received from the service provider. It can be used interchangeably with functions in the C standard library such as **gmtime** or **localtime**. Because it is a 64-bit integer, it is not impacted by the Year 2038 problem. Timestamps can be converted into a local date and time using the **ConvertTimestamp** method.

The string members, such as *lpszContent*, *lpszResponseId*, *lpszModelName*, and *lpszStatusText*, are managed by the library. Applications should treat these pointers as read-only and must not attempt to modify the contents of the referenced strings. If an application needs to retain or modify this data, it should create its own copy.

Calling the **ClearHistory** or **ResetSession** methods will invalidate these string pointers. Applications must not reference these values after the session history has been cleared.

Unless otherwise documented, reserved members should be set to zero before calling a method which accepts this structure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

LLM_SESSION

The **LLM_SESSION** structure contains extended configuration information used by the **ConnectEx** method to establish a session with a language model provider.

```
typedef struct _LLM_SESSION
{
    DWORD dwSize;
    DWORD dwProviderId;
    DWORD dwFlags;
    FLOAT fTemperature;
    FLOAT fTopP;
    LONG  nTopK;
    LONG  nTimeout;
    LONG  nIdleTime;
    LONG  nCacheTime;
    LONG  nMaxTokens;
    DWORD dwReasoningLevel;
    LPCTSTR lpszBaseUrl;
    LPCTSTR lpszModelName;
    LPCTSTR lpszApiKey;
    LPCTSTR lpszApiVersion;
    LPCTSTR lpszAppName;
    LPCTSTR lpszUserId;
    LPCTSTR lpszOrgId;
    LPCTSTR lpszProjectId;
    LPCTSTR lpszSystemPrompt;
} LLM_SESSION, *LPLLM_SESSION;
```

Members

dwSize

The size of this structure, in bytes. This member must be set to `sizeof(LLM_SESSION)` before the structure is used. This value is validated by the library and is reserved for future structure versioning.

dwProviderId

The provider associated with the session. This member should be one of the `LLM_PROVIDER` values. If this value is `LLM_PROVIDER_NONE` the provider ID specified when calling the **LlmConnectEx** method will be used. Refer to the providers page for a list of supported providers and their default models.

dwFlags

Reserved flags for internal use. This member should be set to zero.

fTemperature

The temperature value used to control response randomness. A value of zero indicates that the provider or model default should be used. Unless you have a specific need to specify a temperature, it is recommended that you leave this value set to zero. Providers do not interpret temperature values identically and reasoning models may ignore the value entirely.

fTopP

The nucleus (top-p) sampling value. A value of zero disables top-p sampling and causes the default behavior to be used. It is recommended that you leave this value set to zero. Nucleus sampling is not used with most reasoning models and may be ignored. Although some providers still support setting a top-p value, most discourage using it with their current models.

nTopK

The top-k sampling value. A value of zero disables top-k sampling. It is recommended that you leave this value set to zero. Top-k sampling is not used with most reasoning models and in many cases the value is ignored. Although some providers still support setting a top-k value, most discourage using it with their current models.

nTimeout

The timeout period for requests, in seconds. A value of zero indicates that the default timeout should be used.

nIdleTime

The maximum idle time, in seconds, that an existing HTTP connection may be retained when the `LLM_OPTION_KEEPALIVE` connection option is enabled. If the elapsed idle time exceeds this value, the current connection will be closed and a new connection will be established for the next request. A value of zero indicates that the default idle timeout should be used.

nCacheTime

The length of time, in seconds, that the library may cache provider-specific information. This is primarily used when caching model lists returned by a provider. A value of zero indicates that the default cache behavior should be used.

nMaxTokens

The maximum number of tokens to request for generated output. A value of zero indicates that the provider or model default should be used.

dwReasoningLevel

Specifies the default reasoning level used for requests in this session. Higher levels may improve response quality for complex tasks but can increase latency and token usage.

lpszBaseUrl

A pointer to a null-terminated string which specifies the base URL for the provider endpoint. This member may be NULL to use the default endpoint for the selected provider.

lpszModelName

A pointer to a null-terminated string which specifies the model name to use for the session. For Microsoft Foundry models, this member typically specifies the deployment name. This member may be NULL if the provider defines a default model.

lpszApiKey

A pointer to a null-terminated string which specifies the API key or authentication token used to access the provider. This member may be NULL if authentication is not required or is provided by another mechanism.

lpszApiVersion

A pointer to a null-terminated string which specifies the API version associated with the provider. This member may be NULL if no explicit version is required.

lpszAppName

A pointer to a null-terminated string which specifies an optional application name associated with the session. When provided, this value may be included in the User-Agent string sent with requests. This value may be sanitized by the library before use and may be NULL.

lpszUserId

A pointer to a null-terminated string which specifies an optional user identifier associated with the session. This member may be NULL.

lpszOrgId

A pointer to a null-terminated string which specifies an optional organization identifier associated with the session. This member may be NULL.

lpszProjectId

A pointer to a null-terminated string which specifies an optional project identifier associated with the session. This member may be NULL.

lpszSystemPrompt

A pointer to a null-terminated string which specifies an optional system prompt used to define the initial behavior of the model for the session. This member may be NULL.

Remarks

This structure is used with the **ConnectEx** method to provide extended configuration information when creating a session. It allows an application to customize connection behavior, sampling parameters, model selection, authentication, and other optional settings without requiring a large number of method parameters. Applications that only need to specify the provider, base URL, model name, and API key may use the simpler **Connect** method instead.

The *dwProviderId* member should normally match the provider specified in the **ConnectEx** method call. A value of `LLM_PROVIDER_NONE` may be used when the application relies on the method parameter to select the provider. If conflicting provider values are specified, the method will fail.

In most cases, applications only need to initialize *dwSize*, *dwProviderId*, and the specific members they wish to override. All unused numeric members should be set to zero, and all unused string members should be set to NULL. The library will apply provider-specific defaults when optional values are not specified.

The *lpszApiKey* member is a string value that specifies the API key used to authenticate with the provider. The API key may be provided using a literal string, an environment variable, or a value stored in the Windows Credential Manager. Using an environment variable or secure credential storage is recommended for production applications to avoid exposing sensitive information in source code or application binaries. To specify an environment variable, surround the name in percent (%) symbols, such as `"%OPENAI_API_KEY%"`. To specify a Windows Credential, surround it in braces, such as `"{MyAppName/OpenAI}".`

For production applications, it is recommended that you avoid using literal API key strings and instead use an environment variable or a value stored in the Windows Credential Manager. If you must provide the API key as a literal string, you should take additional steps to protect it, such as storing the key in an encrypted form and limiting access to authorized users or processes. Avoid embedding API keys directly in application source code, configuration files, installers or other content that could be exposed through version control systems, logs or public repositories.

The *dwReasoningLevel* member provides a provider-neutral hint that controls how much internal reasoning a model should use when generating a response. Higher levels may improve the quality of results for more complex tasks, but can also increase response time and token usage. Not all models support reasoning controls, and the exact behavior is provider-specific. In most cases, it is recommended that you set this value to LLM_REASONING_DEFAULT, allowing the provider or model to determine the appropriate level automatically.

The sampling-related members *fTemperature*, *fTopP*, and *nTopK* control how responses are generated. In most applications, adjusting the temperature alone is sufficient, while Top-P and Top-K are intended for more advanced tuning scenarios. If these values are not specified, the provider or model defaults are used. Not all providers or models support sampling parameters such as temperature, top-p or top-k. The library will only include those values when they are supported by the selected provider and model. For models that do not support these parameters, the session values are

ignored.

The connection-related members *lpszBaseUrl*, *nTimeout*, and *nIdleTime* control how requests are sent and how long an existing HTTP connection may be reused. When the `LLM_OPTION_KEEPALIVE` option is enabled, connections may be reused across multiple requests, subject to the idle timeout period.

The *nCacheTime* member controls how long the library may cache provider-specific information, such as model lists. This helps reduce unnecessary network requests when applications repeatedly query provider capabilities.

The *lpszAppName* member specifies the application name associated with requests sent by the control. This value is included as part of the default user-agent string and may be used for diagnostic and identification purposes by the provider. A recommended format is to specify both the application name and version number using a convention similar to standard user-agent strings, for example: `"MyApplication/1.0"`.

The *lpszUserId* member is a user identifier associated with requests sent to the current provider. Some providers allow applications to specify a user identifier as part of the request payload for diagnostics, analytics, rate limiting, or request tracking. Some providers may ignore the value or use it only for internal monitoring and logging purposes. Applications should avoid including sensitive or personally identifiable information in the user identifier value unless required by the provider.

The *lpszOrgId* member specifies an optional organization, tenant or account identifier used by some providers when processing requests. This is primarily intended for enterprise or multi-tenant environments where a provider account may be associated with multiple organizations or projects. Most applications will not need to set this value unless specifically required by the provider. If the current provider does not support organization identifiers, the value is ignored.

The *lpszProjectId* member specifies an optional project identifier used by some providers when processing requests. This is primarily intended for providers which support project-based authentication, billing or resource management. Most applications will not need to set this value unless specifically required by the provider or account configuration. If the current provider does not support project identifiers, the value is ignored.

The *lpszSystemPrompt* member may be used to define a session-level system prompt that establishes the behavior of the model. A system prompt provides instructions that are included with each request sent to the model. It can be used to define the expected role, tone, response style, formatting rules, or other application-specific guidance that should apply to the session. For example, an application might use a system prompt to request short responses, avoid Markdown formatting, return structured text, or answer only within the context of a specific feature or workflow.

The string members in this structure are supplied by the application and are treated as input values when the session is created. Applications should ensure that any referenced strings remain valid until the connection is established. The library makes an internal copy of these values, so the application does not need to maintain them after the connection completes.

LLM_TOKEN_USAGE

The **LLM_TOKEN_USAGE** structure contains information about token usage for a client session.

```
typedef struct _LLM_TOKEN_USAGE
{
    DWORD   dwSize;
    DWORD   dwProviderId;
    DWORD   dwReserved;
    LONG    nMessageCount;
    LONG    nInputTokens;
    LONG    nOutputTokens;
    LONG    nContextUsed;
    LONG    nContextSize;
    TCHAR   szModelName[LLM_MODEL_NAMELEN];
} LLM_TOKEN_USAGE, *LPLLM_TOKEN_USAGE;
```

Members

dwSize

The size of this structure, in bytes. This member must be set to `sizeof(LLM_TOKEN_USAGE)` before the structure is used.

dwProviderId

The provider identifier. This member should be one of the `LLM_PROVIDER` values. Refer to the providers page for a list of supported providers and their default models.

dwReserved

A reserved value for future use. This member will always be zero.

nMessageCount

The number of messages currently stored in the session history.

nInputTokens

The number of input tokens associated with system and user messages in the current session.

nOutputTokens

The number of output tokens generated in model responses for the current session.

nContextUsed

The total number of tokens currently used in the active chat context, including input messages and message history.

nContextSize

The maximum number of tokens supported by the current model for the active context. A value of zero indicates that this limit is not available.

szModelName

A null-terminated string which specifies the name of the model associated with the current session. This value may be empty if no model name is available.

Remarks

This structure is used to return token usage information for an active client session. It provides a summary of how many messages are currently in the session history, how many tokens have been used for input and output, and how much of the available context window is currently in use.

The ***nInputTokens*** member reflects tokens associated with user and system input, while

nOutputTokens reflects tokens generated by the model in its responses. The *nContextUsed* member represents the total token usage currently contributing to the active chat context, including prior message history that may be sent with each request.

The *nContextSize* member indicates the maximum context size supported by the current model, when that information is available. Applications may compare *nContextUsed* with *nContextSize* to estimate how much of the available context window has been consumed.

This structure is intended for informational and diagnostic use. Token counts are provider-dependent and may represent estimates rather than exact values, depending on the model or service in use. Applications should not rely on these values to enforce strict limits, as the provider ultimately determines whether a request exceeds its supported context or token constraints.

Applications should set the *dwSize* member before passing this structure to a method. Unless otherwise documented, reserved members should be set to zero. String values are stored directly in the fixed-length buffers contained within the structure and may be read safely by the application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

CLlmClient Class Constants

Constant	Value	Description
Ports		
LLM_PORT_DEFAULT	0	Use the provider-specific default port.
LLM_PORT_SECURE	443	Default port for secure HTTPS connections.
Protocols		
LLM_PROTOCOL_DEFAULT	0	Use the provider-specific default protocol.
LLM_PROTOCOL_HTTP	1	Use the HTTP protocol.
LLM_PROTOCOL_HTTPS	2	Use the HTTPS protocol.
LLM_PROTOCOL_UNKNOWN	-1	Unknown or invalid protocol.
Options		
LLM_OPTION_NONE	0	No options specified.
LLM_OPTION_NOCACHE	0x000001	Disable provider and model caching for the session.
LLM_OPTION_KEEPALIVE	0x000002	Enable persistent (keep-alive) HTTP connections.
LLM_OPTION_PROXY	0x000008	Use a configured proxy server for the connection.
LLM_OPTION_NOUSERAGENT	0x000020	Do not send a User-Agent header with the request.
LLM_OPTION_SECURE	0x001000	Force use of a secure (HTTPS) connection.
LLM_OPTION_DEFAULT	LLM_OPTION_NONE	Default option set (no flags enabled).
Providers		
LLM_PROVIDER_NONE	0	No provider specified.
LLM_PROVIDER_LOCAL	1	Local inference provider (e.g., LM Studio or Ollama).
LLM_PROVIDER_OPENAI	2	OpenAI provider using the ChatGPT models.

LLM_PROVIDER_ANTHROPIC	3	Anthropic provider using the Claude models.
LLM_PROVIDER_GOOGLE	4	Google AI provider using the Gemini models.
LLM_PROVIDER_MICROSOFT	5	Microsoft Foundry provider using OpenAI-compatible models.
LLM_PROVIDER_MISTRAL	6	Mistral AI provider using the Mistral models.
LLM_PROVIDER_UNKNOWN	((DWORD)-1)	Unknown or unrecognized service provider.
LLM_PROVIDER_DEFAULT	LLM_PROVIDER_LOCAL	Default service provider.
Reasoning		
LLM_REASONING_NONE	0	No reasoning, even if it is available.
LLM_REASONING_DEFAULT	1	Provider or model default.
LLM_REASONING_LOW	2	Prefer faster responses; reduces usage costs.
LLM_REASONING_MEDIUM	3	Balanced reasoning.
LLM_REASONING_HIGH	4	Prefer quality responses; increases usage costs.
LLM_REASONING_MAXIMUM	5	Maximum reasoning quality.
Temperature		
LLM_TEMPERATURE_MINIMUM	0.0	Deterministic output with minimal randomness.
LLM_TEMPERATURE_CONSERVATIVE	0.3	Low variability, more predictable responses.
LLM_TEMPERATURE_BALANCED	0.7	Balanced creativity and coherence.
LLM_TEMPERATURE_DEFAULT	1.0	Standard default sampling behavior.
LLM_TEMPERATURE_CREATIVE	1.2	Increased creativity and variation.
LLM_TEMPERATURE_MAXIMUM	2.0	Maximum randomness with highly varied output.
Top-P Sampling		

LLM_TOP_P_DISABLED	0.0	Nucleus sampling disabled.
LLM_TOP_P_MINIMUM	0.1	Very restrictive token selection.
LLM_TOP_P_CONSERVATIVE	0.8	Conservative token selection.
LLM_TOP_P_BALANCED	0.9	Balanced nucleus sampling.
LLM_TOP_P_CREATIVE	0.95	More diverse token selection.
LLM_TOP_P_MAXIMUM	1.0	Full probability distribution with no filtering.
LLM_TOP_P_DEFAULT	LLM_TOP_P_DISABLED	Default disables nucleus sampling.
Top-K Sampling		
LLM_TOP_K_DISABLED	0	Top-K sampling disabled.
LLM_TOP_K_MINIMUM	0	Equivalent to disabled sampling.
LLM_TOP_K_CONSERVATIVE	10	Restrict to top 10 tokens.
LLM_TOP_K_BALANCED	40	Balanced token selection range.
LLM_TOP_K_CREATIVE	60	More diverse token selection.
LLM_TOP_K_MAXIMUM	100	Wide token selection range.
LLM_TOP_K_DEFAULT	LLM_TOP_K_DISABLED	Default disables Top-K sampling.
Frequency		
LLM_FREQUENCY_DISABLED	0.0	No frequency penalty applied.
LLM_FREQUENCY_MINIMUM	0.0	Minimum frequency penalty.
LLM_FREQUENCY_MAXIMUM	2.0	Maximum frequency penalty.
LLM_FREQUENCY_DEFAULT	LLM_FREQUENCY_DISABLED	Default disables frequency penalty.
Presence		
LLM_PRESENCE_DISABLED	0.0	No presence penalty

		applied.
LLM_PRESENCE_MINIMUM	0.0	Minimum presence penalty.
LLM_PRESENCE_MAXIMUM	2.0	Maximum presence penalty.
LLM_PRESENCE_DEFAULT	LLM_PRESENCE_DISABLED	Default disables presence penalty.
Provider Flags		
LLM_PROVIDER_FLAG_NONE	0	No provider requirements specified.
LLM_PROVIDER_FLAG_REQUIRE_TLS	0x0001	Requires a secure TLS (HTTPS) connection.
LLM_PROVIDER_FLAG_REQUIRE_AUTH	0x0002	Requires authentication (e.g., API key or token).
LLM_PROVIDER_FLAG_API_VERSION	0x0004	Requires an explicit API version parameter.
LLM_PROVIDER_FLAG_LOCAL	0x0008	Locally hosted provider (LM Studio, Ollama, etc.)
LLM_PROVIDER_FLAG_MODEL_LIST	0x0010	Supports enumerating available models.
LLM_PROVIDER_FLAG_MODEL_INFO	0x0020	Supports retrieving detailed model information.
Model Options		
LLM_MODEL_OPTION_DEFAULT	0x0000	default list of chat models for a provider.
LLM_MODEL_OPTION_PREVIEW	0x0001	Include preview or experimental models.
LLM_MODEL_OPTION_STREAMING	0x0002	Include models that support streaming responses.
LLM_MODEL_OPTION_STRUCTURED	0x0004	Include models that support structured outputs.
LLM_MODEL_OPTION_REASONING	0x0008	Include reasoning-oriented models.
LLM_MODEL_OPTION_VISION	0x0010	Include models that support image input.
LLM_MODEL_OPTION_AUDIO	0x0200	Include models that support audio output (text-to-speech).

LLM_MODEL_OPTION_IMAGE	0x0400	Include models that support image generation or input.
LLM_MODEL_OPTION_VIDEO	0x0800	Include models that support video generation.
LLM_MODEL_OPTION_TRANSCRIPTION	0x1000	Include models that support speech-to-text transcription.
LLM_MODEL_OPTION_DEPRECATED	0x8000	Include deprecated or retired models.
LLM_MODEL_OPTION_ALL_MODELS	0xFFFF	Include all available model types.
Model Flags		
LLM_MODEL_FLAG_NONE	0x0000	No model capabilities defined.
LLM_MODEL_FLAG_CHAT	0x0001	Supports conversational text generation.
LLM_MODEL_FLAG_SYSTEM_ROLE	0x0002	Accepts a system role message in the input.
LLM_MODEL_FLAG_STREAMING	0x0004	Supports streaming responses.
LLM_MODEL_FLAG_STRUCTURED	0x0008	Supports structured output (e.g., JSON or schema).
LLM_MODEL_FLAG_VISION	0x0010	Supports image inputs (multimodal).
LLM_MODEL_FLAG_TOOLS	0x0020	Supports tool or function calling.
LLM_MODEL_FLAG_REASONING	0x0040	Supports reasoning-oriented generation.
LLM_MODEL_FLAG_RESPONSES	0x0080	Supports the Responses API (unified endpoint).
LLM_MODEL_FLAG_FUNCTIONS	0x0100	Supports OpenAI-style function calling with schemas.
LLM_MODEL_FLAG_AUDIO	0x0200	Supports audio output (text-to-speech)
LLM_MODEL_FLAG_IMAGE	0x0400	Supports image generation.
LLM_MODEL_FLAG_VIDEO	0x0800	Supports video generation.

LLM_MODEL_FLAG_TRANSCRIPTION	0x1000	Supports speech-to-text transcription.
LLM_MODEL_FLAG_INSTRUCTIONS	0x2000	Supports a dedicated instruction field outside message lists.
LLM_MODEL_FLAG_MAX_COMPLETION_TOKENS	0x4000	Uses `max_completion_tokens` instead of `max_tokens` in requests.
LLM_MODEL_FLAG_INFERRED	0x80000	Capabilities are inferred rather than explicitly defined.
Model Status		
LLM_MODEL_STATUS_NONE	0x0000	No status assigned.
LLM_MODEL_STATUS_AVAILABLE	0x0001	Model is actively available.
LLM_MODEL_STATUS_PREVIEW	0x0002	Model is in preview or experimental stage.
LLM_MODEL_STATUS_DEPRECATED	0x0004	Model is deprecated or legacy.
Limits		
LLM_MAX_MESSAGE_LENGTH	65536	Maximum length of a single input message (64 KB)
LLM_MAX_RESPONSE_LENGTH	262144	Maximum expected response length (256 KB)
LLM_MAX_SYSTEM_PROMPT_LENGTH	32768	Maximum length of the system prompt (32 KB)
LLM_MAX_CHAT_HISTORY	1000	Maximum number of messages stored per session.
LLM_MAX_TOKENS	200000	Maximum token limit per request.
Roles		
LLM_ROLE_UNKNOWN	0	Unknown or invalid role.
LLM_ROLE_USER	1	User input message.
LLM_ROLE_ASSISTANT	2	Assistant response message.
LLM_ROLE_SYSTEM	3	System-level instruction message.

LLM_ROLE_FUNCTION	4	Function call message (legacy)
LLM_ROLE_TOOL	5	Tool-generated message.
LLM_ROLE_TOOLUSER	6	User input directed to a tool.
LLM_ROLE_DEFAULT	LLM_ROLE_USER	Default role is user input.
Responses		
LLM_RESPONSE_UNKNOWN	0	No stop reason specified or unrecognized response state.
LLM_RESPONSE_COMPLETE	1	Response completed normally.
LLM_RESPONSE_LIMITED	2	Stopped due to token or context limits.
LLM_RESPONSE_ABORTED	3	Request was cancelled or interrupted.
LLM_RESPONSE_ERROR	4	An error occurred during processing.
LLM_RESPONSE_TIMEOUT	5	Request timed out.
Session		
LLM_SESSION_FLAG_NONE	0	No session flags specified.
LLM_SESSION_FLAG_DEFAULT	LLM_SESSION_FLAG_NONE	Default session behavior.
Cache		
LLM_INVALID_CACHE_TIME	-1	Indicates an invalid or unspecified cache duration.

Large Language Model Providers

One of the first decisions you will need to make when using the SocketTools **CLlmClient** class is choosing which service provider to use. The class is designed to support a variety of providers and models, and the provider type is specified using one of following provider constants. The current version supports the following providers:

Constant	Value	Default Model	Description
LLM_PROVIDER_LOCAL	1	None	Locally hosted models using servers like LM Studio or Ollama. This is ideal for development, testing, offline use, or avoiding usage costs. A wide range of open-source models are available; for best results, start with smaller instruction-tuned models such as **qwen2.5-7b-instruct**, **llama-3.2-3b-instruct**, or **mistral-7b-instruct**.
LLM_PROVIDER_OPENAI	2	**gpt-5.4-nano**	OpenAI's public API (ChatGPT) is a recommended starting point for most developers due to ease of use, strong general performance, and comprehensive documentation. For initial development and testing, lightweight models such as the GPT-5 mini series provide fast response times and lower usage costs.
LLM_PROVIDER_ANTHROPIC	3	**claude-haiku-4-5**	Anthropic's Claude models are well suited for structured reasoning, conversational clarity, and safety-focused applications. For initial use, the Haiku models offer lower cost and faster response times while maintaining strong performance.
LLM_PROVIDER_GOOGLE	4	**gemini-2.5-flash**	Google's Gemini models are a good choice for multimodal applications and integration with the Google AI ecosystem. The Flash models are recommended for getting started due to their lower latency and reduced token costs.
LLM_PROVIDER_MICROSOFT	5	None	Microsoft Foundry OpenAI-compatible models are typically used in enterprise environments requiring Azure integration and regional deployment control. This option requires provisioning a model deployment within Foundry and specifying the deployment name and API version when connecting.
LLM_PROVIDER_MISTRAL	6	**mistral-small-3.2**	Mistral AI models provide efficient and cost-effective options for general-purpose and

			reasoning tasks. Smaller models are recommended when getting started due to their performance and lower cost.

Although SocketTools provides a default model for most providers, the model names and availability will change over time. The providers which do not have a default model assigned to them will always require a specific model name when establishing the connection. Some providers, notably Microsoft Foundry and locally hosted services, will explicitly require you to provide a model name to establish a connection.

It is important to note that the class is not limited only to those default models listed above. Developers are encouraged to enumerate available models and explicitly select a model that meets their requirements. The class provides methods designed to return information about all of the compatible models supported by a provider. For more information refer to the EnumModels method.

Choosing a Model

Most language model providers offer multiple models with different capabilities, performance characteristics, and pricing. Rather than selecting a specific model name immediately, it is often more useful to choose a general category of model based on your application's needs. Common model categories include:

- **Lightweight**. Optimized for speed and low cost. These are ideal for simple tasks such as formatting, summarization, classification, or user interface interactions where responsiveness is important. These are the default models assigned to supported providers. In most cases, we recommend you start with a lightweight model until you determine your application could benefit from a more capable model type.
- **Balanced**. General purpose models that provide good performance across a wide range of tasks. These are typically the best default choice for most applications which need to balance between performance and capability. Examples are `gpt-5-mini`, `claude-sonnet-4-6`, `gemini-3.1` and `mistral-medium` models.
- **Reasoning**. Designed for more complex tasks such as multi-step problem solving, analysis, and code generation. These models may produce more detailed responses but typically use more tokens and have higher latency and increased costs. Examples are `gpt-5`, `claude-opus-4-7`, `gemini-3.1-pro` and `mistral-large` models.
- **Multimodal**. Support input or output beyond plain text, such as images, audio, or structured data. These are useful when working with media content or advanced integrations.

In most cases, developers should begin with a lightweight or balanced model and only move to more advanced models when additional capability is required. The exact model names and capabilities will vary between providers, but these categories provide a useful framework for selecting an appropriate model. Applications should also avoid relying on strict token limits or attempting to precisely manage context usage. Providers ultimately determine request limits, and applications should be prepared to handle responses that are truncated or rejected when limits are exceeded.

API Keys and Authentication

Most language model providers require an API key (or authentication token) to access their services. An API key is a unique identifier associated with your account that is included with each request to authenticate the client and track usage.

When using the **CLlmClient** class, the API key is typically provided when establishing a session using the **Connect** method. The class will include this key in requests to the selected provider using the

appropriate authentication mechanism.

Because API keys grant access to external services and may incur usage charges, they should be handled carefully and not exposed unnecessarily. The class supports several methods for providing API keys, allowing applications to balance convenience and security.

Providing an API Key

The class supports the following methods for supplying an API key:

- **Literal string**
  The API key can be provided directly as a string when creating a session. This is the simplest approach and is often used for testing or development, but it is not recommended for production applications because the key may be exposed in application binaries or source code.
- **Environment variable**
  The API key can be stored in an environment variable and retrieved at runtime. This approach avoids embedding the key directly in the application and is commonly used in development environments, scripts, or deployment pipelines.
- **Windows Credential Manager**
  The API key can be stored securely using the Windows Credential Manager and retrieved by the application at runtime. This is the recommended approach for Windows applications because it provides secure storage and helps prevent accidental exposure of sensitive credentials.

Best Practices

- Do not embed API keys directly in source code for production applications.
- Use secure storage mechanisms, such as the Windows Credential Manager, whenever possible.
- Limit access to API keys and avoid sharing them between applications or users.
- Review provider usage policies and configure usage limits or alerts where available.

Each provider has its own process for creating and managing API keys. Refer to the provider documentation for details on generating keys, rotating credentials, and managing access.

Application Design

When designing an application that uses a language model provider, developers generally have two approaches for managing API keys:

- **Application-managed API key**
  The developer provides an API key that is used by the application for all requests. This approach is simple to implement and provides a consistent user experience, but the developer is responsible for all usage and any associated costs.
- **User-provided API key (Bring Your Own Key)**
  The application allows the end user to supply their own API key, typically through a configuration dialog or settings interface. In this case, the user is responsible for usage and costs, and the application acts as a client using the user's credentials.

Each approach has trade-offs. Using an application-managed key simplifies the user experience but may require safeguards such as rate limiting or usage monitoring. Allowing users to provide their own key can reduce operational costs and provide greater flexibility, but requires additional user interface considerations and clear instructions for obtaining and configuring API access.

Applications intended for a broad audience often prefer a built-in API key for ease of use, while developer-focused tools frequently support user-provided keys for flexibility.

Provider Overview

The following sections provide more detailed information about the supported providers. One of the advantages of the **CLlmClient** class is that applications are not limited to a single language model service. Different providers may offer advantages related to pricing, performance, regional availability, deployment flexibility, or model capabilities.

Supporting multiple providers can also provide greater flexibility for end users. Some users or organizations may already have existing accounts, billing arrangements, or infrastructure associated with a specific provider such as OpenAI, Google, Microsoft Foundry, or a locally hosted inference service. Applications can allow users to select the provider and model which best meets their requirements without requiring significant changes to application logic.

LLM_PROVIDER_LOCAL

This provider type is used for locally hosted language model inference. This is particularly useful for development, testing, and experimentation without relying on a cloud-based provider. Local hosting allows developers to evaluate model behavior, test integrations, and work offline or within a private environment. This requires you to install and configure an application on your local system or network which will provide the inference service. For the Windows platform, we recommend one of the following applications, which are free to install and use:

LM Studio

LM Studio provides a full-featured desktop environment for running and testing language models locally. It includes model management, a built-in server, and support for OpenAI-compatible APIs, making it a strong choice for development and evaluation.

- LM Studio
- LM Studio Documentation

Ollama

Ollama is a lightweight local model runtime that makes it easy to download and run models on a local system. It provides a simple API interface and is well suited for basic testing and self-hosted deployments.

- Ollama
- Ollama Documentation

LLM_PROVIDER_OPENAI

The OpenAI provider connects to OpenAI's public API and is generally the recommended starting point for most developers. It offers a wide range of well-documented models, consistent API behavior, and strong general-purpose performance. Developers who are new to using large language models or want a reliable default should typically begin here.

To get started, developers create an API key, select a model name, and connect to the default OpenAI endpoint. The API is widely supported and serves as the baseline for compatibility with many other providers.

- OpenAI Platform
- OpenAI Documentation
- Manage API Keys

LLM_PROVIDER_ANTHROPIC

The Anthropic provider connects to Anthropic's Claude API, which focuses on conversational models designed for safety and structured reasoning. Developers must create an API key and select a supported Claude model. The API is similar in concept to OpenAI but uses its own endpoints and request formats.

- Anthropic
- Claude Documentation

LLM_PROVIDER_GOOGLE

The Google provider connects to Google's Gemini API, which provides access to multimodal models and integrates with the broader Google AI ecosystem. Developers typically obtain an API key through Google AI Studio and use it to authenticate requests to the Gemini service.

- Google AI
- Google Documentation

LLM_PROVIDER_MICROSOFT

The Microsoft provider connects to a Microsoft Foundary OpenAI-compatible deployment. This option is often used in enterprise environments where Azure integration, regional deployment, or Microsoft-managed infrastructure is required. Unlike the public OpenAI API, Microsoft requires a resource-specific endpoint, a deployment name instead of a direct model name, and an explicit API version. Authentication is typically performed using an API key.

- Microsoft Foundry
- Azure OpenAI Reference

LLM_PROVIDER_MISTRAL

The Mistral provider connects to Mistral AI's hosted API service. Mistral models are designed to provide strong general-purpose and reasoning performance while maintaining efficient resource usage and competitive pricing. Developers who want a balance between capability, response speed, and lower operational cost may find these models to be a good alternative to larger commercial providers. Some organizations may prefer Mistral AI due to regional deployment considerations or compatibility with European-based infrastructure and services.

Message History File Format

The **CLlmClient** class uses a JSON-formatted message history file to support exporting and importing conversation state between application sessions. This format is used by the **ExportHistory** and **ImportHistory** methods and is intended to provide a simple, human-readable representation of the conversation history associated with a client session.

A message history file contains both the messages sent by the client application and the responses generated by the model. Together, these entries represent the conversational context for the session. The file does not contain information about the client session, aside from the provider type and model name. It does not contain user names, authorization tokens or any information related to the service account.

The history file may contain sensitive or private information, including user prompts, model responses or application-specific data. Applications should take reasonable precautions to protect these files, particularly if they are stored, transmitted or made available for users to download.

The following example shows a simplified message history file containing a single message turn:

```
{
  "version": 1,
  "provider": 1,
  "created": 1715000000,
  "messages": [
    {
      "message": {
        "role": 1,
        "reasoning": 0,
        "flags": 0,
        "id": 1,
        "timestamp": 1715000001,
        "maxTokens": 0,
        "inputTokens": 12,
        "content": "Hello"
      },
      "response": {
        "role": 2,
        "flags": 0,
        "messageId": 1,
        "status": 1,
        "elapsed": 812,
        "timestamp": 1715000002,
        "outputTokens": 24,
        "model": "gpt-5.4-nano",
        "content": "Hi there."
      }
    }
  ],
  "messageCount": 1,
  "model": "gpt-5.4-nano"
}
```

File Structure

A message history file consists of a root JSON object which contains session metadata and an array of message turns.

version

The format version number used by the exported history file.

provider

The numeric provider identifier associated with the session.

created

A Unix timestamp value which indicates when the history file was created.

messages

An array containing the exported message turns.

messageCount

The number of message turns stored in the history file.

model

The default model name associated with the exported session.

Message Turns

Each entry in the **`messages`** array represents a complete message turn consisting of two objects:

- A **`message`** object which contains the client input
- A **`response`** object which contains the model output

The fields within these objects closely correspond to members of the **`LLM_MESSAGE`** and **`LLM_RESPONSE`** structures used internally by the API.

Applications should not depend on undocumented fields or the exact formatting of exported history files. Future versions of the library may add additional fields or metadata while maintaining compatibility with previous versions where possible.

Remarks

The message history format is intended primarily for exporting, importing and persisting conversation state between application sessions. Although the file format is human-readable JSON text, applications should avoid modifying exported history files unless they fully understand the relationship between the stored values.

Changing values such as the provider identifier, model name, message role or status values may produce undefined or unexpected results when the history is imported. Applications should not modify role identifiers or assume that numeric values used internally by the API will remain unchanged in future versions.

Modifying the message or response content may also invalidate related metadata such as token usage values. For example, changing the **`content`** field may result in incorrect **`inputTokens`** or **`outputTokens`** values being associated with the imported conversation history.

Mail Message Class Library

Compose and parse standard MIME formatted email messages.

Reference

- Class Methods
- Error Codes

Library Information

Class Name	CMailMessage
File Name	CSMSGV12.DLL
Version	12.0.3024.1286
LibID	123A728A-D6CD-435F-A76D-0BA3C07DDFC1
Import Library	CSMSGV12.LIB
Dependencies	None
Standards	RFC 822, RFC 2045, RFC 2046, RFC 2047, RFC 2048

Overview

The Mail Message class provides an interface for composing and processing email messages and newsgroup articles which are structured according to the Multipurpose Internet Mail Extensions (MIME) standard. Using this class, an application can easily create complex messages which include multiple alternative content types, such as plain text and styled HTML text, file attachments and customized headers.

It is not required that the developer understand the complex MIME standard; a single method call can be used to create multipart message, complete with a styled HTML text body and support for international character sets. The Mail Message class can be easily integrated with the other mail related protocol libraries, making it extremely easy to create and process MIME formatted messages.

SocketTools also includes a class for managing a local message storage file that can be used to store and retrieve multiple messages. Methods are provided to open and create storage files, add, remove and extract messages from storage, and search the stored messages for specific header field values. For more information, refer to the CMessageStore class.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). You should install all updates for your development tools and have the current Windows SDK installed. The minimum supported version of Visual Studio is Visual Studio 2010 with Service Pack 1 (SP1) installed. The SocketTools header files are designed to be compatible with all modern C/C++ compilers and we also provide function definitions for several additional languages such as Object Pascal and Visual Basic.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are deploying applications to Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. If you are deploying applications to Windows 8, you must have the 8.1 update installed. If you are targeting the Windows on ARM platform, the minimum required version is Windows 10 build 1709.

SocketTools includes support for both 64-bit and 32-bit Windows platforms. All current versions of Windows are 64-bit, and we include 32-bit x86 libraries to maintain compatibility with legacy development tools. SocketTools also provides native ARM64 libraries for systems running Windows on ARM. Note that 32-bit applications on ARM use x86 emulation, and Microsoft no longer supports native 32-bit ARM (ARM32) applications. Embarcadero's C++Builder and Delphi compilers (as of version 12.3) do not support building native ARM64 applications for Windows. For developing applications targeting the Windows on ARM platform, we recommend using Visual Studio 2019 or later.

The import libraries included with SocketTools are provided in several different formats. The most commonly used format is COFF, which is available for x64, x86 and native ARM64 platforms. For compatibility with older Borland (Embarcadero) compilers, we also provide OMF libraries for x86 platforms and ELF libraries for x64 platforms. If you are using Visual Studio, you will want to use the standard COFF import libraries. Note that some languages may not require import libraries and will link to the exported functions in the DLL based on the function declaration itself.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Mail Message Class Methods

Class	Description
CMailMessage	Constructor which initializes the current instance of the class
~CMailMessage	Destructor which releases resources allocated by the class
Method	Description
AddHeaders	Add one or more header values to the current message
AppendText	Append text to the body of the current message part
AttachData	Attach the contents of a buffer to the current message
AttachFile	Attach a file to the current message
AttachHandle	Attach the current message handle to this instance of the class
AttachImage	Attach an inline image to the current message
CheckAuthenticationResults	Check the authentication status for the current message
Clear	Clear the current message, deleting all message parts
ClearText	Clear the body of the current message part
Close	Close the current message
CompareType	Compare the message contents against the specified content type
CompareText	Compare text in the body of the current message part
Compose	Compose a new message using the specified parameters
Copy	Copy the contents of another message into the current message
CreatePart	Create a new message part for the current message
DecodeText	Decode a base64 or quoted-printable encoded string
DeleteHeader	Delete the specified header field from the message
DeletePart	Delete the current message part
DetachHandle	Detach the handle for the current instance of this class
EncodeText	Encode a string using base64 or quoted-printable encoding
EnumAttachments	Enumerate all file attachments in the current message
EnumHeaders	Enumerate all header fields in the current message part
EnumRecipients	Enumerate addresses of all message recipients
Export	Export the current message to a string buffer or text file
ExtractAllFiles	Extract all file attachments in the message and store them in the specified directory
ExtractFile	Extract the file attachment from the current message part
FindAttachment	Search for a file attachment in the current message
FindText	Search for a regular expression or string literal in the current message text

FormatDate	Return a standard RFC 822 formatted date string
GetAllHeaders	Return the complete RFC 822 header values in a string buffer
GetAllRecipients	Return a comma-separated list of recipient addresses in a string buffer
GetAttachedFileName	Return the name of the file attachment for the current part
GetAuthenticationResults	Return information about the authentication status of the message
GetBoundary	Return the multipart message boundary string
GetContentDigest	Return encoded digest of message's content
GetContentLength	Return the length of the current message part content
GetContentType	Return the content type identifier for the current message part
GetDate	Return the date and time from the message header
GetErrorString	Return a description for the specified error code
GetExportOptions	Return a bitmask that describes current message export options
GetFileType	Return the content type for a specified file
GetFilteredText	Return the filtered contents for the current message part
GetFirstHeader	Return the first header field and value in the current message part
GetHandle	Return the message handle used by this instance of the class
GetHeader	Return the value of a specified header from the message
GetLastError	Return the last error code
GetLinks	Returns the hyperlinks in the current message part
GetNextHeader	Return the next header field and value in the current message part
GetPart	Return the current message part index
GetPartCount	Return the total number of message parts
GetSender	Return the email address of the message sender
GetSize	Return the size of the complete message in bytes
GetText	Return the text of the current message part
GetTextLength	Return the length of the text in the current message part
Import	Import a message from the specified text file, clipboard or buffer
IsContentType	Determine if the message part matches the specified content type
IsInitialized	Determine if the class has been successfully initialized
LocalizeText	Localize Unicode text to ANSI using a specific character set
NormalizeText	Normalize Unicode text, eliminating confusable homoglyphs and symbols
Open	Open and parse the specified text file as a MIME formatted message
ParseAddress	Parse the specified email address
ParseDate	Parse the specified RFC 822 formatted date string
ParseHeader	Parse the specified text and add to message header

ParseText	Parse the specified text and add to the current message
SetExportOptions	Specify a bitmask that describes current message export options
SetFileType	Set the content type for a specific file name extension
SetLastError	Set the last error code
SetDate	Set the current date in the header for the current message
SetHeader	Create or update a header field in the current message
SetPart	Set the current message part index for the current message
SetText	Create or update the current message body
ShowError	Display a message box with a description of the specified error

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

AddHeaders Method

```
BOOL AddHeaders(
   LPCTSTR lpszHeaderList
);
```

The **AddHeaders** method adds one or more headers to the specified message.

Parameters

lpszHeaderList

A null-terminated string which specifies one or more header values which should be set for the specified message. This parameter cannot be NULL.

Return Value

If the method succeeds, the return value is non-zero. If the string contains one or more invalid headers, the method returns a value of zero. To get extended error information, call the **GetLastError** method.

Remarks

The **AddHeaders** method enables your application to set one or more header values by providing a list of name/value pairs separated by a colon. Multiple header values may be provided by separating them with a newline character. This method is similar to calling the **SetHeader** method for each value. When the list of header values is parsed, extraneous whitespace is ignored; however, if the header list contains invalid text (for example, a missing colon separating a header name from its value) the method will fail and an error will be returned.

This method will only add or update header values in the main header block for the message. It cannot be used to update header values in a specific section of a multipart message. If you need to add or change a header value in a specific part of the message, use the **SetHeader** method.

When adding custom, application-specific header values you should always prefix them with "X-" to avoid conflicting with standard headers.

Example

```
// Define a list of header values which should be included with the
// main header block for the message
LPCTSTR lpszHeaderList = _T("X-App-Sender: someuser@domain.tld\n") \
                         _T("X-App-Version: 1.5\n") \
                         _T("X-App-Mailer: AppMail (Win64)\n")

if (! pMessage->AddHeaders(lpszHeaderList))
{
    // Unable to add headers for this message
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CMailMessage::CMailMessage Method

```
CMailMessage();
```

The **CMailMessage** constructor initializes the class library and validates the license key at runtime.

Remarks

If the constructor fails to validate the runtime license, subsequent methods in this class will fail. If the product is installed with an evaluation license, then the application will only function on the development system and cannot be redistributed.

The constructor calls the **MimeInitialize** function to initialize the library, which dynamically loads other system libraries and allocates thread local storage. If you are using this class within another DLL, it is important that you do not create or destroy an instance of the class from within the **DllMain** function because it can result in deadlocks or access violation errors. You should not declare static or global instances of this class within another DLL if it is linked with the C runtime library (CRT) because it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

~CMailMessage, IsInitialized

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CMailMessage::~CMailMessage

```
~CMailMessage();
```

The **CMailMessage** destructor releases resources allocated by the current instance of the **CMailMessage** object. It also uninitializes the library if there are no other concurrent uses of the class.

Remarks

When a **CMailMessage** object goes out of scope, the destructor is automatically called to allow the library to free any resources allocated on behalf of the process. All handles that were client session are destroyed.

The destructor is not called explicitly by the application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CMailMessage

CMailMessage::AppendText Method

```
LONG AppendText(
   LPCTSTR lpszText
);
```

The **AppendText** method appends the specified text to the body of the current message part.

Parameters

lpszText

A null-terminated string which specifies the text to be appended to the current message part.

Return Value

If the method succeeds, the return value is the number of bytes copied into the message. A return value of zero indicates that no text could be appended to the current message part. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

CMailMessage::AttachData Method

```
BOOL AttachData(
   LPBYTE lpBuffer,
   LONG cbBuffer,
   LPCTSTR lpszContentName,
   LPCTSTR lpszContentType,
   DWORD dwOptions
);

BOOL AttachData(
   CString& strBuffer,
   LPCTSTR lpszContentName,
   LPCTSTR lpszContentType,
   DWORD dwOptions
);
```

The **AttachData** method attaches the contents of the buffer to the message.

Parameters

lpBuffer

Pointer to a byte buffer which contains the data to be attached to the message. This parameter may be NULL, in which case no data is attached, but an additional empty message part will be created. An alternate form of this method accepts a **CString** object which contains the text to be attached to the message.

cbBuffer

An unsigned integer which specifies the number of bytes of data in the buffer pointed to by the *lpBuffer* parameter. If the *lpBuffer* parameter is NULL, this value must be zero.

lpszContentName

Pointer to a string which specifies a name for the data being attached to the message. This typically is used as a file name by the mail client to store the data in. If this parameter is NULL or an empty string then no name is defined and the data is attached as inline content. Note that if a file name is specified with a path, only the base name will be used.

lpszContentType

Pointer to a string which specifies the type of data being attached. The value must be a valid MIME content type. If this parameter is NULL or an empty string, then the buffer will be examined to determine what kind of data it contains. If there is only text characters, then the content type will be specified as "text/plain". If the buffer contains binary data, then the content type will be specified as "application/octet-stream", which is appropriate for any type of data.

dwOptions

A value which specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
MIME_ATTACH_DEFAULT	The data encoding is based on the content type. Text data is not encoded, and binary data is encoded using the standard base64 encoding algorithm.
MIME_ATTACH_BASE64	The data is always encoded using the standard base64 algorithm, even if the buffer only contains printable text

	characters.
MIME_ATTACH_UUCODE	The data is always encoded using the uuencode algorithm, even if the buffer only contains printable text characters.
MIME_ATTACH_QUOTED	The data is always encoded using the quoted-printable algorithm. This encoding should only be used if the data contains 8-bit text characters.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **AttachData** method allows an application to attach data to the message as either a file attachment or as inline content. The recipient of the message will see the attached data in the same way that they would see a file attached to the message using the **AttachFile** method.

If the specified message is not a multipart message, it is marked as multipart and the attached file is appended to the message. If the message is already a multipart message, an additional part is created and the attachment is added to the message.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CMailMessage::AttachFile Method

```
BOOL AttachFile(
   LPCTSTR lpszFileName,
   DWORD dwOptions
);
```

The **AttachFile** method attaches the specified file to the message.

Parameters

lpszFileName

Pointer to a string which specifies the name of the file to be attached to the message.

dwOptions

A value which specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
MIME_ATTACH_DEFAULT	The file attachment encoding is based on the file content type. Text files are not encoded, and binary files are encoded using the standard base64 encoding algorithm. This is the default option for file attachments.
MIME_ATTACH_BASE64	The file attachment is always encoded using the standard base64 algorithm, even if the attached file is a plain text file.
MIME_ATTACH_UUCODE	The file attachment is always encoded using the uuencode algorithm, even if the attached file is a plain text file.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

If the specified message is not a multipart message, it is marked as multipart and the attached file is appended to the message. If the message is already a multipart message, an additional part is created and the attachment is added to the message.

To attach data that is stored in a memory buffer rather than a file, use the **AttachData** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CMailMessage::AttachHandle Method

```
VOID AttachHandle(
   HMESSAGE hMessage
);
```

The **AttachHandle** method attaches the specified message handle to the current instance of the class.

Parameters

hMessage

The handle to the message that will be attached to the current instance of the class object.

Return Value

None.

Remarks

This method is used to attach a message handle created outside of the class using the SocketTools API. Once the handle is attached to the class, the other class member functions may be used with that message.

If a message handle has already been created for the class, that handle will be released when the new handle is attached to the class object. If you want to prevent the previous message from being destroyed, you must call the **DetachHandle** method. Failure to release the detached handle may result in a resource leak in your application.

Note that the ***hMessage*** parameter is presumed to be a valid message handle and no checks are performed to ensure that the handle is valid. Specifying an invalid message handle will cause subsequent method calls to fail.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

See Also

DetachHandle, GetHandle

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CMailMessage::AttachImage Method

```
BOOL AttachImage(
   LPCTSTR lpszImageFile,
   LPCTSTR lpszContentId
);
```

The **AttachImage** method attaches the specified file to the message as an inline image.

Parameters

lpszImageFile

Pointer to a string which specifies the name of the image file to be attached to the message. This parameter cannot be NULL and must specify the name of an existing file.

lpszContentId

An optional pointer to a null-terminated string which specifies the content ID associated with the inline image. If this parameter is NULL, a random content ID string will be automatically generated.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **AttachImage** method enables an application to attach an inline image to the message. Unlike a normal file attachment, this method is designed to be used with HTML formatted email messages that display images attached to the message. The ***lpszContentId*** parameter specifies the content ID string that is used with the HTML image tag to reference that image.

If the specified message is not a multipart message, it is marked as multipart and the attached image file is appended to the message. If the message is already a multipart message, an additional part is created and the attachment is added to the message.

To attach regular files to the message, use the **AttachFile** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

CMailMessage::CheckAuthenticationResults Method

```
BOOL CheckAuthenticationResults(
    DWORD dwAuthFlags
);
```

The **CheckAuthenticationResults** method checks if the authentication status in the message matches one or more values.

Parameters

dwAuthFlags

A bitmask that specifies one or more authentication flags to check for. These can be any combination of the values listed below.

Value	Description
MIME_AUTH_SPF_PASSED	The message passed the Sender Policy Framework (SPF) check. The sender's IP address was authorized to send mail for the domain in the envelope sender address.
MIME_AUTH_SPF_FAILED	The message failed the SPF check. The sending mail server is not authorized by the domain's SPF record to send mail on its behalf.
MIME_AUTH_DKIM_PASSED	The message passed the DomainKeys Identified Mail (DKIM) check. The signature applied by the sender was successfully verified using the domain's public key.
MIME_AUTH_DKIM_FAILED	The message failed the DKIM check. The signature could not be verified or did not match the message content, suggesting it may have been altered.
MIME_AUTH_DMARC_PASSED	The message passed DMARC evaluation. The message aligned with a valid SPF or DKIM result based on the sender domain's policy.
MIME_AUTH_DMARC_FAILED	The message failed DMARC evaluation. It did not pass SPF or DKIM checks in a way that aligns with the domain's published policy.
MIME_AUTH_TEMP_ERROR	A temporary error occurred while evaluating one or more authentication mechanisms. This may indicate a DNS lookup timeout or other transient failure.
MIME_AUTH_PERM_ERROR	A permanent error occurred during authentication checks. This may indicate a malformed DNS record or invalid message structure that prevents proper evaluation.

Return Value

This method returns a non-zero value if one or more of the specified flags match the values found in the message's `Authentication-Results` header. If there is no match, the method returns zero. This method explicitly clears the last error code to assist in differentiating between an actual error condition (such as an invalid message handle) and a case where no authentication data matched.

Remarks

This method provides a convenient way to check if the authentication status of the message matches one or more values. In addition to the flags specified above, the following predefined flag combinations are also available:

- MIME_AUTH_PASSED is a combination of all passing results (SPF, DKIM, DMARC).
- MIME_AUTH_FAILED is a combination of all failing results.
- MIME_AUTH_ERROR is a combination of temporary or permanent errors.

This method allows for quick checks against common authentication outcomes using predefined flags. For example, to check whether the message failed authentication or encountered a temporary error, you could specify `MIME_AUTH_FAILED | MIME_AUTH_TEMP_ERROR`.

For more information about SPF, DKIM and DMARC, please refer to the **GetAuthenticationResults** method.

Example

```
if (mailMessage.Open(lpszFileName))
{
    // Check if any of the SPF, DKIM, or DMARC checks failed
    if (mailMessage.CheckAuthenticationResults(MIME_AUTH_FAILED))
        _tprintf(_T("This message has failed one or more authentication
checks\n"));

    mailMessage.Close();
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

CMailMessage::Clear Method

```
BOOL Clear();
```

The **Clear** method clears the header and body of the specified message, and deletes all message parts.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

CMailMessage::ClearText Method

```
BOOL ClearText();
```

The **ClearText** method deletes the text from the body of the current message part.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

AppendText, CompareText, GetText, SetText

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CMailMessage::CompareType Method

```
BOOL CompareType(
   INT nMessagePart,
   LPCTSTR lpszContentType
);

BOOL CompareType(
   LPCTSTR lpszContentType
);
```

The **CompareType** method compares the content type for the message part against the specified content type.

Parameters

nMessagePart

An integer value which specifies which part of the message to compare against the content type. A value of zero returns compares the content type against the main message header, while a value greater than zero compares the content type against the content type for a specific part of a multipart message. If this parameter is omitted, the content type will be compared against the current message part.

lpszContentType

Pointer to a string which specifies the content type to compare against. This parameter cannot be NULL and it must specify a valid MIME media type. It is permitted to omit the media subtype, in which case the content type match will only be made against the base type. For example, both **"application/pdf"** and **"application"** are permitted as valid content types. Note that this is a prefix match, not a wildcard pattern match.

Return Value

The method will return a non-zero value if the specified content type matches the content type for the message part. If the content types do not match or one of the parameters is invalid, the method will return zero. To get extended error information, call the **GetLastError** method. If the parameters are valid but the content types do not match, the last error code will be set to NO_ERROR.

Remarks

The **CompareType** method is used to compare the content type for a specific part of a MIME-encoded message against a known media type. Multipurpose Internet Mail Extensions (MIME) defines a standard way of classifying the content of an email message or its individual parts, such as plain text, HTML, images, or file attachments.

A MIME media type, also referred to as a content type, is typically expressed in the form **type/subtype**. For example, the content type **text/plain** identifies unformatted plain text, while **text/html** identifies HTML formatted text. The content type for each message part is typically specified in its **Content-Type** header field. This method performs a case-insensitive comparison between the message part's declared content type and the type provided by the caller. It does not consider optional parameters, such as character encoding or boundary markers. For example, a content type of **"text/html; charset=UTF-8"** will match **"text/html"**.

The following table lists some of the most common MIME media types used in email messages:

Media Type	Description

`text/plain`	Plain text with no formatting
`text/html`	HTML-formatted text, commonly used for rich email content
`multipart/alternative`	Message that contains multiple representations of the same content, such as both plain text and HTML
`multipart/mixed`	Message that includes a combination of text and attachments
`multipart/related`	Message that includes related resources, such as inline images referenced by HTML content
`image/jpeg`	JPEG image
`image/png`	PNG image
`application/pdf`	PDF document
`application/octet-stream`	Generic binary data, typically used for file attachments

To obtain the full content type string for a message part, including any optional parameters, use the **GetHeader** method with the header name `"Content-Type"`.

Example

```
// Search the message for a PDF attachment by checking the content type
// for each part of a multipart message.
//
// If the content type matches "application/pdf" then that message part
// should contain a PDF attachment. We prompt the user where to store
// the file and then exit the loop.

INT nParts = mailMessage.GetPartCount();

for (INT nMessagePart = 1; nMessagePart < nParts; nMessagePart ++)
{
    if (mailMessage.SetPart(nMessagePart) == MIME_ERROR)
        break;

    if (mailMessage.CompareType(_T("application/pdf")))
    {
        TCHAR szAttachment[MAX_PATH] = _T("");

        // Get the name of the file attached to the message. This can be
        // useful for display purposes, but exercise caution if you want
        // to use that name to store the file locally.
        if (mailMessage.GetAttachedFileName(szAttachment, MAX_PATH))
        {
            _tprintf(_T("Found attachment \"%s\" in part %d\n"), szAttachment,
nMessagePart);

            // The recommended approach is to prompt your user for where
            // they would like you to store store the file attachment;
            // avoid using the remote filename directly without validating
            // or prompting the user.
            TCHAR szLocalFile[MAX_PATH] = _T("");

            OPENFILENAME ofn = {0};
            ofn.lStructSize = sizeof(OPENFILENAME);
            ofn.hwndOwner = NULL; // No owner window
```

```
            ofn.lpstrFilter = "Text Files (*.txt)\0*.txt\0All Files (*.*)\0*.*\0";
            ofn.lpstrFile = szLocalFile;
            ofn.nMaxFile = MAX_PATH;
            ofn.lpstrTitle = "Select File to Save";
            ofn.Flags = OFN_OVERWRITEPROMPT;

            // If the user cancels the dialog, we are finished
            if (!GetSaveFileName(&ofn))
                 break;

            // Extract the attachment to the file name specified by the user
            if (!mailMessage.ExtractFile(szLocalFile))
            {
                DWORD dwError = mailMessage.GetLastError();
                _tprintf(_T("Failed to extract file (Error 0x%08lX)\n"), dwError);
            }
        }
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

CMailMessage::CompareText Method

```
BOOL CompareText(
   LONG *lpnOffset,
   LPCTSTR lpszText,
   LONG cchText,
   BOOL bCaseSensitive
);
```

The **CompareText** method compares a text string against the contents of the current message part.

Parameters

lpnOffset

Pointer to a long integer which specifies the offset in the message at which to begin the comparison. This value will be updated when the method returns to indicate the offset position in the message where the comparison ended.

lpszBuffer

Pointer to a string buffer which contains the text that is to be compared against the body of the message.

cchBuffer

The number of characters in the buffer that should be compared against the body of the message.

bCaseSensitive

Boolean flag which specifies that the comparison should be case sensitive.

Return Value

If the text buffer matches the contents of the current message body, the method will return a non-zero value, and the ***lpnOffset*** argument will be set to position in the buffer where the match terminated. If the text buffer does not match, the method will return a value of zero, and the ***lpnOffset*** argument will be set to the position of the first non-matching character. The method will also return zero if one of the arguments is invalid. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

CMailMessage::Compose Method

```
BOOL Compose(
   LPCTSTR lpszFrom,
   LPCTSTR lpszTo,
   LPCTSTR lpszCc,
   LPCTSTR lpszSubject,
   LPCTSTR lpszMessageText,
   LPCTSTR lpszMessageHTML,
   UINT nCharacterSet,
   UINT nEncodingType
);
```

The **Compose** method creates a new message using the specified parameters.

Parameters

lpszFrom

A null-terminated string which specifies the sender's email address. This parameter may be NULL, in which case no sender address will be included in the message header.

lpszTo

A null-terminated string which specifies one or more recipient addresses. If multiple addresses are specified, each address must be separated by a comma. This parameter may be NULL, in which case no recipient addresses will be included in the message header.

lpszCc

A null-terminated string which specifies one or more addresses that will receive a copy of the message in addition to the listed recipients. If multiple addresses are specified, each address must be separated by a comma. This parameter may be NULL, in which case no carbon-copy addresses will be included in the message header.

lpszSubject

A null-terminated string which specifies the subject of the message. This parameter may be NULL, in which case no subject will be included in the message.

lpszMessageText

A null-terminated string which contains the body of the message as plain text. Each line of text contained in the string should be terminated with a carriage-return and linefeed (CRLF) pair, which is recognized as the end-of-line. If this parameter is NULL or points to an empty string, then the message will have an empty body unless the ***lpszMessageHTML*** parameter is not NULL.

lpszMessageHTML

A null-terminated string which contains the message using HTML formatting. If the ***lpszMessageText*** parameter is not NULL, then a multipart message will be created with both plain text and HTML text as the alternative. This allows mail clients to select which message body they wish to display. If the ***lpszMessageText*** argument is NULL or points to an empty string, then the message will only contain HTML. Although this is supported, it is not recommended because older mail clients may be unable to display the message correctly.

nCharacterSet

A numeric identifier which specifies the character set to use when composing the message. A value of zero specifies that the default UTF-8 character set should be used. It is recommended that you always use UTF-8 when composing a new message or creating a new message part.

nEncodingType

A numeric identifier which specifies the encoding type to use when composing the message. A value of zero specifies that default 7bit encoding should be used. The following values may also be used:

Value	Description
MIME_ENCODING_7BIT	Each character is encoded in one or more bytes, with each byte being 8 bits long, with the most significant bit cleared. This encoding is most commonly used with plain text using the US-ASCII character set, where each character is represented by a single byte in the range of 20h to 7Eh.
MIME_ENCODING_8BIT	Each character is encoded in one or more bytes, with each byte being 8 bits long and all bits are used. 8-bit encoding is typically used with multibyte character sets and is the default encoding used with Unicode text.
MIME_ENCODING_QUOTED	Quoted-printable encoding is designed for textual messages where most of the characters are represented by the ASCII character set and is generally human-readable. Non-printable characters or 8-bit characters with the high bit set are encoded as hexadecimal values and represented as 7-bit text. Quoted-printable encoding is typically used for messages which use character sets such as ISO-8859-1, as well as those which use HTML.
MIME_ENCODING_BASE64	Base64 encoding converts binary or text data to ASCII by translating it so each base64 digit represents 6 bits of data. This encoding method is commonly used with messages that contain binary data (such as binary file attachments), or when text uses extended characters that cannot be represented by 7-bit ASCII. It is recommended that you use base64 encoding with Unicode text.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

email addresses may be specified as simple addresses, or as commented addresses that include the sender's name or other information. For example, any one of these address formats are acceptable:

```
user@domain.tld
User Name <user@domain.tld>
user@domain.tld (User Name)
```

To specify multiple addresses, you should separate each address by a comma or semi-colon. Note that the *lpszFrom* parameter cannot specify multiple addresses, however it is permitted with the *lpszTo*, *lpszCc* and *lpszBcc* parameters.

To send a message that contains HTML, it is recommended that you provide both a plain text version of the message body and an HTML formatted version. While it is permitted to send a message that only contains HTML, some older mail clients may not be capable of displaying the message correctly.

In some cases, anti-spam software will increase the spam score of messages that do not contain a plain text message body. This can result in your message being rejected or quarantined by the mail server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

CMailMessage::Copy Method

```
BOOL Copy(
   CMailMessage *pMessage
);
```

The **Copy** method copies the contents of the specified message.

Parameters

pMessage

A pointer to a CMailMessage object which contains the message to be copied. If this argument is NULL, the current message contents will be cleared.

Return Value

If the message was successfully copied, the method will return a non-zero value. If the method fails, it will return value of zero. To get extended error information, call **GetLastError**.

Remarks

This method is used to create a copy of the specified message, replacing the current message contents. Note that this method creates a duplicate of the message referenced by the *pMessage* object, and any subsequent changes to the contents of the original message will not be reflected in the copy of that message.

Example

```
CMailMessage *pMessage1 = new CMailMessage();
CMailMessage *pMessage2 = new CMailMessage();

// Compose a test message
pMessage1->Compose(_T("Bob Jones <bob@example.com>"),
                           _T("Tom Smith <tom@example.com>"),
                           NULL,
                           _T("This is a test message"),
                           _T("This is a test, this is only a test."));

// Create a copy of the message and change the subject
// The original subject in pMessage1 remains unchanged
if (pMessage2->Copy(pMessage1))
{
    CString &strSubject;
    if (pMessage2->GetHeader(0, _T("Subject"), strSubject))
    {
        strSubject = _T("Re: ") + strSubject;
        pMessage2->SetHeader(0, _T("Subject"), strSubject);
    }
}
```

CMailMessage::CreatePart Method

```
INT CreatePart();

INT CreatePart(
   LPCTSTR lpszText,
   UINT nCharacterSet,
   UINT nEncodingType
);
```

The **CreatePart** method creates a new part for the specified message. If this the first part created for a message that does not have the multipart content type specified, the message is marked as multipart and the header fields are updated.

Parameters

lpszText

A null-terminated string which specifies the text to be included in the body of the new message part. If this parameter is NULL or points to an empty string, no text is added to the message part.

nCharacterSet

A numeric identifier which specifies the character set to use when composing the message. A value of zero specifies the character set should be the same character set used to initially compose the message. It is recommended that you always use UTF-8 when composing a new message or creating a new message part.

nEncodingType

A numeric identifier which specifies the encoding type to use when composing the message. A value of zero specifies that default 7bit encoding should be used. The following values may also be used:

Value	Description
MIME_ENCODING_7BIT	Each character is encoded in one or more bytes, with each byte being 8 bits long, with the most significant bit cleared. This encoding is most commonly used with plain text using the US-ASCII character set, where each character is represented by a single byte in the range of 20h to 7Eh.
MIME_ENCODING_8BIT	Each character is encoded in one or more bytes, with each byte being 8 bits long and all bits are used. 8-bit encoding is typically used with multibyte character sets and is the default encoding used with Unicode text.
MIME_ENCODING_QUOTED	Quoted-printable encoding is designed for textual messages where most of the characters are represented by the ASCII character set and is generally human-readable. Non-printable characters or 8-bit characters with the high bit set are encoded as hexadecimal values and represented as 7-bit text. Quoted-printable encoding is typically used for messages which use character sets such as ISO-8859-1, as well as those which use HTML.
MIME_ENCODING_BASE64	Base64 encoding converts binary or text data to ASCII by translating it so each base64 digit represents 6 bits of data.

	This encoding method is commonly used with messages that contain binary data (such as binary file attachments), or when text uses extended characters that cannot be represented by 7-bit ASCII. It is recommended that you use base64 encoding with Unicode text.

Return Value

If the method succeeds, the return value is the new message part number. If the method fails, the return value is MIME_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

CMailMessage::DecodeText Method

```
LONG DecodeText(
   LPCTSTR lpszInput,
   LONG cchInput,
   LPTSTR lpszOutput,
   LONG cchOutput,
   UINT nCharacterSet,
   UINT nEncodingType
);

LONG DecodeText(
   LPCTSTR lpszInput,
   LONG cchInput,
   CString& strOutput,
   UINT nCharacterSet,
   UINT nEncodingType
);
```

The **DecodeText** method decodes a string that was previously encoded using base64 or quoted-printable encoding.

Parameters

lpszInput

A null-terminated string which contains the encoded text. This parameter cannot be a NULL pointer.

cchInput

An integer value which specifies the number of characters of text in the input string which should be decoded. If this parameter is omitted or the value is -1, the entire length of the string up to the terminating null will be decoded.

lpszOutput

A null-terminated string buffer that will contain the decoded text. This buffer must be large enough to store all of the characters in the decoded text, including the terminating null character. This parameter cannot be NULL. An alternate version of this method accepts a **CString** object instead of a fixed-length string buffer.

cchOutput

An integer value which specifies the maximum number of characters which can be copied into the output string buffer. The buffer must be large enough to store all of the decoded text and terminating null character. This value must be greater than zero. This parameter is not used if output buffer is specified as a **CString** object.

nCharacterSet

A numeric identifier which specifies the character set to use when decoding the input text. A value of zero specifies the character set is undefined and no Unicode text conversion is performed when the input string is decoded. If this value does not match the character set used when the text was originally encoded, the resulting output text may be invalid. This parameter may be omitted, in which case the method will default to using the UTF-8 character set.

nEncodingType

An integer value that specifies the encoding method used. This parameter may be omitted, or it may be one of the following values:

Value	Description
MIME_ENCODING_QUOTED	Quoted-printable encoding is designed for textual messages where most of the characters are represented by the ASCII character set and is generally human-readable. Non-printable characters or 8-bit characters with the high bit set are encoded as hexadecimal values and represented as 7-bit text. Quoted-printable encoding is typically used for messages which use character sets such as ISO-8859-1, as well as those which use HTML.
MIME_ENCODING_BASE64	Base64 encoding converts binary or text data to ASCII by translating it so each base64 digit represents 6 bits of data. This encoding method is commonly used with messages that contain binary data (such as binary file attachments), or when text uses extended characters that cannot be represented by 7-bit ASCII. It is recommended that you use base64 encoding with Unicode text. This is the default encoding type used by this method.

Return Value

If the input buffer can be successfully decoded, the return value is the length of the decoded output string. If the method returns zero, then no text was decoded and the output string buffer will be empty. If the method fails, the return value is MIME_ERROR. To get extended error information, call **GetLastError**.

Remarks

This method provides a means to decode text that was previously encoded using either base64 or quoted-printable encoding. In most cases, it is not necessary to use this method because the message parser will detect which character set and encoding was used, then automatically decode the message text if necessary.

The value of the ***nCharacterSet*** parameter does not affect the resulting output text, it is only used when decoding the input text. If the Unicode version of this method is called, the output text will be converted to UTF-16 and returned to the caller. If the ANSI version of this method is used, the decoded output will always be returned to the caller using the UTF-8 character set.

If the ***nCharacterSet*** parameter is specified as MIME_CHARSET_UTF16, the encoding type must be MIME_ENCODING_BASE64. Other encoding methods are not supported for Unicode strings and will cause the method to fail. In most cases, it is preferable to use MIME_ENCODING_BASE64 as the encoding method, with quoted-printable encoding only used for legacy support.

If an unsupported encoding type is specified, this method will return MIME_ERROR and the output text string will be empty. This method cannot be used to decode uuencoded text.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

CMailMessage::DeleteHeader Method

```
BOOL DeleteHeader(
   LPCTSTR lpszHeader
);
```

The **DeleteHeader** method deletes the specified header field from the message.

Parameters

lpszHeader

Pointer to a string which specifies the header field that will be deleted.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetHeader, SetHeader

CMailMessage::DeletePart Method

```
BOOL DeletePart(
   INT nMessagePart
);
```

The **DeletePart** method deletes the specified message part from the multipart message. The memory allocated for the message part is released.

Parameters

nMessagePart

The message part index to delete.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method cannot be used to delete part zero, which is the main body of the message. Instead use the **Clear** method to clear the entire message.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CMailMessage::DetachHandle Method

```
HMESSAGE DetachHandle();
```

The **DetachHandle** method detaches the client handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the message handle associated with the current instance of the class object. If there is no active client session, the value INVALID_MESSAGE will be returned.

Remarks

This method is used to detach a message handle created by the class for use with the SocketTools API. Once the message handle is detached from the class, no other class member functions may be called. Note that the handle must be explicitly released at some later point by the process or a resource leak will occur.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

See Also

CMailMessage::EncodeText Method

```
LONG EncodeText(
   LPCTSTR lpszInput,
   LONG cchInput,
   LPTSTR lpszOutput,
   LONG cchOutput,
   UINT nCharacterSet,
   UINT nEncodingType
);

LONG EncodeText(
   LPCTSTR lpszInput,
   LONG cchInput,
   CString& strOutput,
   UINT nCharacterSet,
   UINT nEncodingType
);
```

The **EncodeText** method encodes a string using base64 or quoted-printable encoding.

Parameters

lpszInput

A null-terminated string which contains the encoded text. This parameter cannot be a NULL pointer.

cchInput

An integer value which specifies the number of characters of text in the input string which should be encoded. If this parameter is omitted or the value is -1, the entire length of the string up to the terminating null will be encoded.

lpszOutput

A null-terminated string buffer that will contain the encoded text. This buffer must be large enough to store all of the characters in the encoded text, including the terminating null character. This parameter cannot be NULL. An alternate version of this method accepts a **CString** object instead of a fixed-length string buffer.

cchOutput

An integer value which specifies the maximum number of characters which can be copied into the output string buffer. The buffer must be large enough to store all of the encoded text and terminating null character. This value must be greater than zero.

nCharacterSet

A numeric identifier which specifies the character set to use when encoding the input text. A value of zero specifies the character set is undefined and no Unicode text conversion is performed when the input string is encoded.

nEncodingType

An integer value that specifies the encoding method used. It may be one of the following values:

Value	Description
MIME_ENCODING_QUOTED	Quoted-printable encoding is designed for textual messages where most of the characters are represented by the ASCII character set and is generally human-readable. Non-printable characters or 8-bit characters with the high bit set

	are encoded as hexadecimal values and represented as 7-bit text. Quoted-printable encoding is typically used for messages which use character sets such as ISO-8859-1, as well as those which use HTML.
MIME_ENCODING_BASE64	Base64 encoding converts binary or text data to ASCII by translating it so each base64 digit represents 6 bits of data. This encoding method is commonly used with messages that contain binary data (such as binary file attachments), or when text uses extended characters that cannot be represented by 7-bit ASCII. It is recommended that you use base64 encoding with Unicode text.

Return Value

If the input buffer can be successfully encoded, the return value is the length of the encoded output string. If the method returns zero, then no text was encoded and the output string buffer will be empty. If the method fails, the return value is MIME_ERROR. To get extended error information, call **GetLastError**.

Remarks

This method provides a means to encode text using either base64 or quoted-printable encoding. It is not necessary to use this method to encode text when using the **SetText** method. The class will automatically encode message text which contains non-ASCII characters using the character set specified when the message is created.

If the *nCharacterSet* parameter parameter is non-zero, the method will encode the text using the specified character set. If the Unicode version of this method is called, the input text is converted to ANSI using the code page associated with the character set. If the ANSI version of this method is called, the input text is converted to Unicode using the system default code page, and then back to ANSI using the specified character set.

If the *nCharacterSet* parameter specifies the MIME_CHARSET_UTF16 character set, you must specify MIME_ENCODING_BASE64 as the encoding method. Other encoding methods are not supported for Unicode strings and will cause the method to fail. It is not recommended you encode text as UTF-16 unless there is a specific requirement to use that character set.

It is recommended that you use the MIME_CHARSET_UTF8 character set whenever possible. It is capable of encoding all Unicode code points, and is a standard for virtually all modern Internet applications. In most cases, it is preferable to use MIME_ENCODING_BASE64 as the encoding method, with quoted-printable encoding only used for legacy support.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

CMailMessage::EnumAttachments Method

```
INT EnumAttachments(
   LPCTSTR* lpFileNames,
   INT nMaxFiles
);
```

The **EnumAttachments** method enumerates all of the file attachments in the current message.

Parameters

lpFileNames

A pointer to a an array of null-terminated strings that contain the names of the files attached to the message. If this parameter is NULL, the method will only return the number of files attached to the message.

nMaxFiles

An integer value that specifies the maximum size of the array of string pointers specified by the *lpFileNames* parameter. If this value is zero, the *lpFileNames* parameter is ignored and the method will only return the number of files attached to the message.

Return Value

If the method succeeds, the return value is the number of files attached to the message. If the message does not contain any file attachments, this method will return a value of zero. If the method fails, the return value is MIME_ERROR. To get extended error information, call **GetLastError**.

Example

```
LPCTSTR lpszFiles[MAXFILES];

INT nFiles = pMessage->EnumAttachments(lpszFiles, MAXFILES);
if (nFiles == MIME_ERROR)
{
    DWORD dwError = pMessage->GetLastError();
    _tprintf(_T("Unable to enumerate attachments, error 0x%08lx\n"), dwError);
    return;
}

_tprintf(_T("There are %d files attached to the message\n"), nFiles);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

CMailMessage::EnumHeaders Method

```
INT EnumHeaders();

INT EnumHeaders(
   LPCTSTR *lpHeaderList,
   INT nMaxHeaders
);
```

The **EnumHeaders** method returns a list of pointers to all header field names in the current message part. This can be used in conjunction with the **GetHeader** method to retrieve the values for every header in the message.

Parameters

lpHeaderList

Pointer to an array of pointers to null-terminated header field names. If this parameter is NULL, the method only returns the number of headers in the current message part.

nMaxHeaders

The maximum number of header fields which may be returned in the *lpHeaderList* parameter.

Return Value

If the method succeeds, the return value is the total number of headers that are defined in the current message part. If the method fails, the return value is MIME_ERROR. To get extended error information, call **GetLastError**.

Remarks

The values returned in the header list array must not be directly modified by the application. There is no specific order in which the header fields are enumerated by this method. The header fields from an imported message may not be returned in the same order as which they appear in the message. An application should never make an assumption about the order in which one or more header fields are defined.

If this method is called without any arguments, it returns the number of headers in the current message part but does not return any data. This is useful for determining how much memory must be allocated for the *lpHeaderList* argument.

Example

```
// Determine the total number of headers in the current
// message part

nHeaders = pMessage->EnumHeaders();
if (nHeaders > 0)
{

    // Allocate memory for the list of headers

    lpHeaderList = (LPCTSTR *)malloc(nHeaders * sizeof(LPCTSTR));
    assert(lpHeaderList != NULL);

    // Retrieve the list of headers in the current
    // message part, and get their values

    pMessage->EnumHeaders(lpHeaderList, nHeaders);
```

```
    for (nIndex = 0; nIndex < nHeaders; nIndex++)
    {

         LPCTSTR lpszValue;
         lpszValue = pMessage->GetHeader(lpHeaderList[nIndex]);
         assert(lpszValue != NULL);

         printf("%s: %s\n", lpHeaderList[nIndex], lpszValue);

    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

CMailMessage::EnumRecipients Method

```
INT EnumRecipients(
   LPCTSTR lpszExtraAddress,
   LPTSTR lpBuffer,
   LPDWORD lpcchBuffer
);

INT EnumRecipients(
   LPTSTR lpBuffer,
   LPDWORD lpcchBuffer
);

INT EnumRecipients(
   CStringArray& arrayRecipients,
   LPCTSTR lpszExtraAddress
);
```

The **EnumRecipients** method returns a null-terminated list of strings which contain the email address of each recipient for the specified message.

Parameters

lpszExtraAddress

A null-terminated string which contains one or more additional email addresses that should be included in the list, in addition to those found in the message. If more than one address is specified, each address should be separated by a comma. This parameter may be NULL if there are no extra addresses to include in the recipient list.

lpBuffer

Pointer to buffer which will contain zero or more null-terminated strings. The end of the string list is indicated by an additional terminating null. If this parameter is NULL, the method will calculate the minimum number of characters required to store the addresses and return the value in the *lpcchBuffer* parameter.

lpcchBuffer

A pointer to an unsigned integer which should be initialized to the maximum number of characters that can be copied into the buffer specified by the *lpBuffer* parameter. When the method returns, it will be updated to contain the actual number of characters copied into the buffer. If the *lpBuffer* parameter is NULL, then this value will contain the minimum number of characters required to store all of the recipient addresses in the current message.

arrayRecipients

A reference to a **CStringArray** object that will contain each of the recipient addresses specified in the message. This version of the method is only available if the program is compiled using Microsoft Foundation Classes (MFC).

Return Value

If the method succeeds, the return value is the total number of recipients for the current message. If the method fails, the return value is MIME_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **EnumRecipients** method returns a list of recipient email addresses for the specified message,

with each address being terminated by a null character. The end of the list is indicated by an additional null character. To determine the size of the buffer you should pass to this function, you can specify the *lpBuffer* parameter as NULL and initialize the value of the *lpcchBuffer* parameter to zero.

An alternative to the **EnumRecipients** method is the **GetAllRecipients** method that returns a comma-separated list of recipient addresses in a string buffer.

Example

```
LPTSTR lpRecipients = NULL;
DWORD cchRecipients = 0;
INT nRecipients = 0;

// Determine the number of characters that should be allocated to store
// all of the recipient addresses in the current message

nRecipients = pMessage->EnumRecipients(NULL, &cchRecipients);

// Allocate the memory for the string buffer that will contain all
// of the recipient addresses and call EnumRecipients
// again to store those addresses in the buffer

if (nRecipients > 0 && cchRecipients > 0)
{
    lpRecipients = (LPTSTR)::LocalAlloc(LPTR, (cchRecipients * sizeof(TCHAR));
    if (lpRecipients == NULL)
        return; // Virtual memory exhausted

    nRecipients = pMessage->EnumRecipients(lpRecipients,
                                           &cchRecipients);
}

// Move through the buffer, processing each recipient address
// that was returned

if (nRecipients > 0)
{
    LPTSTR lpszAddress = lpRecipients;
    INT cchAddress;

    while (lpszAddress != NULL)
    {
        if ((cchAddress = lstrlen(lpszAddress)) == 0)
            break;

        // lpszAddress specifies a recipient address
        // Advance to the next address string in the buffer
        lpszAddress += cchAddress + 1;
    }
}

if (lpRecipients != NULL)
{
    LocalFree((HLOCAL)lpRecipients);
    lpRecipients = NULL;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

CMailMessage::Export Method

```
BOOL Export(
   LPCTSTR lpszFileName,
   DWORD dwExportOptions
);

BOOL Export(
   HGLOBAL *lphBuffer,
   LPDWORD lpdwBufferSize,
   DWORD dwExportOptions
);

BOOL Export(
   LPTSTR lpszMessage,
   DWORD dwMessageSize,
   DWORD dwExportOptions
);

BOOL Export(
   CString& strMessage,
   DWORD dwExportOptions
);
```

The **Export** method exports the message to a file, the system clipboard or global memory buffer.

Parameters

lpszFileName

A null-terminated string which specifies the file name that will contain the message. If the file already exists, it will be overwritten with the message contents.

lpszMessage

A null-terminated string which will contain the message. An alternate form of this method accepts a pointer to a global memory handle which will contain the message data when the method returns.

dwMessageSize

An unsigned integer value which specifies the maximum size of the ***lpszMessage*** buffer.

dwExportOptions

An unsigned integer which specifies how the message will be exported. The following values may be combined using a bitwise Or operator:

Value	Description
MIME_OPTION_DEFAULT	The default export options. The headers for the message are written out in a specific consistent order, with custom headers written to the end of the header block regardless of the order in which they were set or imported from another message. If the message contains Bcc, Received, Return-Path, Status or X400-Received header fields, they will not be exported.
MIME_OPTION_KEEPORDER	The original order in which the message header fields were set or imported are preserved when the message is exported.

MIME_OPTION_ALLHEADERS	All headers, including the Received, Return-Path, Status and X400-Received header fields will be exported. Normally these headers are not exported because they are only used by the mail transport system. This option can be useful when exporting a message to be stored on the local system, but should not be used when exporting a message to be delivered to another user.
MIME_OPTION_NOHEADERS	When exporting a message, the main header block will not be included. This can be useful when creating a multipart message for services which expect MIME formatted data, such as HTTP POST requests. This option should never be used for email messages being submitted using SMTP.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

If the version of this method is used which exports the message to a pre-allocated string buffer, the *dwMessageSize* parameter must specify the maximum size of the buffer. If the method succeeds, the message will be copied to the buffer. If the method fails, the previous contents of the buffer will not be preserved. If the buffer provided is not large enough to store the entire message, the message contents will be truncated. The **GetSize** method can be used to determine the minimum size of the buffer required to store the complete message.

If the version of this method is used which returns an HGLOBAL memory handle to the caller, the handle must be dereferenced using the **GlobalLock** function. No changes should be made to this copy of the message. If you wish to modify the contents of the message, allocate a local buffer and make a copy of the message contents, or use the method which exports the message to a pre-allocated string buffer. Your application is responsible for calling **GlobalUnlock** and **GlobalFree** to unlock and free the handle when it is no longer needed.

Example

```
// Exports the message contents to a global buffer
HGLOBAL hgblMessage = NULL;
DWORD dwMessageSize = 0;

if (pMessage->Export(&hgblMessage, &dwMessageSize))
{
    LPBYTE lpMessage = (LPBYTE)GlobalLock(hgblMessage);

    if (lpMessage)
    {
        // Process the contents of the message
    }

    GlobalUnlock(hgblMessage);
    GlobalFree(hgblMessage);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

CMailMessage::ExtractAllFiles Method

```
INT ExtractAllFiles(
   LPCTSTR lpszDirectory
);
```

The **ExtractAllFiles** method extracts all of the file attachments in a message and stores them in the specified directory.

Parameters

lpszDirectory

A null-terminated string which specifies the name of the directory where the file attachments should be stored. If this parameter is NULL or points to an empty string, the attached files will be stored in the current working directory on the local system.

Return Value

If the method succeeds, the return value is the number of file attachments which were extracted from the message. If the message does not contain any file attachments, this method will return a value of zero. If the method fails, the return value is MIME_ERROR. To get extended error information, call **GetLastError**.

Remarks

This method will extract all of the files that are attached to the message and store them in the specified directory. The directory must exist and the current user must have the appropriate permissions to create files there. If a file with the same name as the attachment already exists, it will be overwritten with the contents of the attachment. If the file attachment was encoded using base64 or uuencode, this function will automatically decode the contents of the attachment.

To determine the file names for each of the attachments in a message, use the **EnumAttachments** method. To store a file attachment on the local system using a name that is different than the file name of the attachment, use the **ExtractFile** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

MimeAttachFile, EnumAttachments, Export, ExtractFile, GetAttachedFileName, Import

CMailMessage::ExtractFile Method

```
BOOL ExtractFile(
   INT nMessagePart,
   LPCTSTR lpszFileName
);

BOOL ExtractFile(
   LPCTSTR lpszAttachment,
   LPCTSTR lpszFileName
);

BOOL ExtractFile(
   LPCTSTR lpszFileName
);
```

The **ExtractFile** method extracts a file attachment from the message and stores it on the local system.

Parameters

nMessagePart

An integer value that specifies the message part that contains the file attachment. This value may be -1, in which case the current message part will be used.

lpszAttachment

A null-terminated string that specifies the file name for the attachment in the message. If the file name of the attachment is not known, this parameter can be NULL or point to an empty string.

lpszFileName

A null-terminated string that specifies the name of a file on the local system. If this parameter is NULL or points to an empty string, the value of the ***lpszAttachment*** parameter will specify the name of the file in the current working directory. If both the ***lpszAttachment*** and ***lpszFileName*** parameters are NULL, the method will fail.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method will store the contents of a file attachment in the current message part to the specified file on the local system. If a path is specified as part of the file name, it must exist and the current user must have the appropriate permissions to create the file. If a file with the same name already exists, it will be overwritten with the contents of the attachment. If the file attachment was encoded using base64 or uuencode, this method will automatically decode the contents of the attachment.

If the ***nMessagePart*** parameter is specified, then an attachment in that message part will be stored in the specified file. If the message part does not contain a file attachment, the method will fail.

If the ***lpszAttachment*** parameter is specified, the method will search the entire message for an attachment with the same file name. The search is not case-sensitive, however it must match the attachment file name completely. This method will not match partial file names or names that include wildcard characters. If a match is found, the contents of that attachment will be stored in the file specified by the ***lpszFileName*** parameter.

To extract all of the files attached to a message in a single method call, use the **ExtractAllFiles**

method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

CMailMessage::FindAttachment Method

```
INT FindAttachment(
   LPCTSTR lpszFileName
);
```

The **FindAttachment** method searches the message for an attachment with the specified file name.

Parameters

lpszFileName

Pointer to a string that specifies the name of the file attachment to search for. This parameter should only specify a base file name; it should not include a file path and cannot be NULL.

Return Value

If the method succeeds, the return value is the message part number that contains an attachment that matches the specified file name. If the message does not contain an attachment with the specified file name, the method will return MIME_ERROR. To get extended error information, call **GetLastError**.

Remarks

This method will search the message for a attachment that matches the specified file name. The search is not case-sensitive, however it must match the attachment file name completely. This method will not match partial file names or names that include wildcard characters. To obtain a list of all of the files attached to a message, use the **EnumAttachments** method.

Example

```
// The name of the file attachment to search for
LPCTSTR lpszFileName = _T("MyProject.docx");

// Search for the attached file and store it on the local system
INT nMessagePart = pMessage->FindAttachment(lpszFileName);
if (nMessagePart != MIME_ERROR)
{
    pMessage->SetPart(nMessagePart);

    if (pMessage->ExtractFile(lpszFileName) != MIME_ERROR)
        _tprintf(_T("Saved file attachment %s\n"), lpszFileName);
    else
    {
        _tprintf(_T("Unable to save file attachment %s\n"), lpszFileName);
        return;
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

CMailMessage::FormatDate Method

```
LPTSTR FormatDate(
   LONGLONG nSeconds,
   LONG nTimezone,
   LPTSTR lpszDate,
   INT cchMaxDate
);

LPTSTR FormatDate(
   LONGLONG nSeconds,
   LPTSTR lpszDate,
   INT cchMaxDate
);

LPTSTR FormatDate(
   LONGLONG nSeconds,
   LONG nTimezone,
   CString& strDate
);

LPTSTR FormatDate(
   LONGLONG nSeconds,
   CString& strDate
);
```

The **FormatDate** converts the specified date, expressed as the number of seconds since 1 January 1970, into a string compatible with the RFC 822 standard format for email messages.

Parameters

nSeconds

A 64-bit integer which specifies the number of seconds since 1 January 1970 00:00:00 UTC. This date is commonly called the epoch, and is the base date used by the standard C/C++ time methods. If the value of this parameter is zero, the current date and time is used.

nTimezone

A 32-bit integer which is set to the difference in seconds between the specified date's timezone and Coordinated Universal Time. A value of zero specifies Coordinated Universal Time, while a positive value specifies a timezone west of UTC, and a negative value specifies a timezone east of UTC. For example, the Eastern timezone would be specified as the value 18000 and the Pacific timezone would be the value 28800. If this argument is omitted from the method, then the current timezone is used.

lpszDate

A buffer which will contain the formatted date as a null-terminated string. This parameter cannot be a NULL pointer.

cchMaxDate

The maximum number of characters, including the terminating null character, which may be copied into the date string buffer.

Return Value

If the method succeeds, a pointer to the date string buffer is returned. If the method fails, a NULL pointer is returned. To get extended error information, call **GetLastError**.

Remarks

The date string is returned in a standard format as outlined in RFC 822, the document which describes the basic structure of Internet email messages. This format is as follows:

```
www, dd mmm yyyy hh:mm:ss [-]zzzz
```

Each part of the date string is defined as follows:

Format	Description
www	Weekday
dd	Day
mmm	Month
yyyy	Year
hh	Hour (24-hour clock)
mm	Minutes
ss	Seconds
zzzz	Timezone

The weekday and month are displayed using standard three-character English abbreviations. The timezone is displayed as the difference (in hours and minutes) between the specified timezone and Coordinated Universal Time. For example, if the timezone is eight hours west of Coordinated Universal Time, the ***nTimezone*** value would be 28800. This would be displayed as -0800 in the formatted date string.

Note that the format of the date string is defined by the RFC 822 standard, and is not affected by localization settings on the host system.

Previous versions of this method represented date and time values as 32-bit integers, which limited the representable range to dates before 19 January 2038 (the so-called "Year 2038 problem"). After this date, 32-bit time values will overflow, resulting in incorrect date calculations and potential failures in software that processes email message dates. By contrast, this 64-bit version uses 64-bit integer values, matching the standard **`time_t`** type used by modern C/C++ libraries. This not only eliminates the Year 2038 limitation but also ensures compatibility with current and future systems, allowing correct handling of dates both far in the past and well into the future. Whenever possible, applications should transition to these 64-bit functions to ensure long-term reliability and portability.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

CMailMessage::GetAllHeaders Method

```
INT GetAllHeaders(
   LPTSTR lpszHeaders,
   INT nMaxLength
);

INT GetAllHeaders(
   CString& strHeaders
);
```

The **GetAllHeaders** method returns the complete RFC 822 header values in a string buffer.

Parameters

lpszHeaders

Pointer to string buffer which will contain the header values for the current message. This parameter may be NULL, in which case the method will calculate the number of characters needed to store the complete header block.

nMaxLength

An integer value which specifies the maximum number of characters that can be stored in the ***lpszHeaders*** string. If the ***lpszHeaders*** parameter is NULL, this value must be zero. If the ***lpszHeaders*** parameter is not NULL, this value must be large enough to store the entire list of addresses.

strHeaders

A **CString** object that will contain the header values for the current message. This version of the method is available if MFC or ATL is being used by the application, and the memory required to store the complete header block will be calculated automatically.

Return Value

If the method succeeds and the ***lpszHeaders*** parameter is NULL, the return value is the minimum number of characters that should be allocated to store all of the header values, including the terminating null character. If the ***lpszHeaders*** parameter is not NULL, then the return value is the number of characters copied into the string, not including the terminating null character. If the method fails, the return value is MIME_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetAllHeaders** method will return all of the RFC 822 header values in a string buffer. This includes the message headers that are most commonly referred to, such as the To, From and Subject headers. Each header and its value are separated by a colon, and terminated with a carriage return and linefeed (CRLF) pair.

The headers and their values returned by this method will not be identical to the header block in the original message. If a header value is split across multiple lines, this method will fold the text, returning the complete header value on a single line of text and removing any extraneous whitespace. If the header value has been encoded by the mail client, this method will return the decoded value, not the original encoded value.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CMailMessage::GetAllRecipients Method

```
INT GetAllRecipients(
   LPCTSTR lpszExtraAddress,
   LPTSTR lpszRecipients,
   INT nMaxLength
);

INT GetAllRecipients(
   CString& strRecipients,
   LPCTSTR lpszExtraAddress
);
```

The **GetAllRecipients** method returns a comma-separated list of recipient addresses in a string buffer.

Parameters

lpszExtraAddress

A null-terminated string which contains one or more additional email addresses that should be included in the list, in addition to those found in the message. If more than one address is specified, each address should be separated by a comma. This parameter may be NULL if there are no extra addresses to include in the recipient list.

lpszRecipients

Pointer to string buffer which will contain a comma-separated list of email addresses when the method returns. This parameter may be NULL, in which case the method will calculate the number of characters needed to store the complete list.

nMaxLength

An integer value which specifies the maximum number of characters that can be stored in the *lpszRecipients* string. If the *lpszRecipients* parameter is NULL, this value must be zero. If the *lpszRecipients* parameter is not NULL, this value must be large enough to store the entire list of addresses.

Return Value

If the method succeeds and the *lpszRecipients* parameter is NULL, the return value is the minimum number of characters that should be allocated to store the list recipient addresses, including the terminating null character. If the *lpszRecipients* parameter is not NULL, then the return value is the number of characters copied into the buffer, not including the terminating null character. If the method returns a value of zero, then the specified message has no recipients. If the method fails, the return value is MIME_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetAllRecipients** method is useful for creating a list of message recipients that can be passed to methods like **CSmtpClient::SendMessage**. If you wish to dynamically allocate the string buffer that will contain the list of recipients, then the *lpszRecipients* parameter should be NULL and the *nMaxLength* parameter should have a value of zero. The method will then return the recommended size of the buffer that should be allocated. This value is guaranteed to be large enough to store the entire list of message recipients, including the terminating null character.

Example

```
CString strRecipients;
```

```
if (pMessage->GetAllRecipients(strRecipients) < 1)
{
    // There are no recipients for the current message
    AfxMessageBox(IDS_ERROR_NO_RECIPIENTS);
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CMailMessage::GetAttachedFileName Method

```
BOOL GetAttachedFileName(
   LPTSTR lpszFileName,
   INT cchFileName
);

BOOL GetAttachedFileName(
   CString& strFileName
);
```

The **GetAttachedFileName** method returns the file name for the attachment to the current message part.

Parameters

lpszFileName

Pointer to a buffer that will contain the current attachment file name as a string. An alternate form of this method accepts a **CString** object which will contain the file name when the method returns.

cchFileName

The maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The method will first try to get the filename from the Content-Disposition header field. If this field does not exist, it then attempts to get the name from the Content-Type header field. If neither field exists, the method will fail.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

CMailMessage::GetAuthenticationResults Method

```
DWORD GetAuthenticationResults();
```

The **GetAuthenticationResults** method returns information about the authentication status of the message.

Parameters

None.

Return Value

This method returns one or more flags based on the value of the `Authentication-Results` header in the message. This method explicitly clears the last error code to assist in differentiating between an error condidition, such as an invalid message handle, and when no authentication information was available. The following flags are defined:

Value	Description
MIME_AUTH_NONE	The message does not contain an Authentication-Results header or does not include any recognizable authentication types and their associated results.
MIME_AUTH_SPF_PASSED	The message passed the Sender Policy Framework (SPF) check. The sender's IP address was authorized to send mail for the domain in the envelope sender address.
MIME_AUTH_SPF_FAILED	The message failed the SPF check. The sending mail server is not authorized by the domain's SPF record to send mail on its behalf.
MIME_AUTH_DKIM_PASSED	The message passed the DomainKeys Identified Mail (DKIM) check. The signature applied by the sender was successfully verified using the domain's public key.
MIME_AUTH_DKIM_FAILED	The message failed the DKIM check. The signature could not be verified or did not match the message content, suggesting it may have been altered.
MIME_AUTH_DMARC_PASSED	The message passed DMARC evaluation. The message aligned with a valid SPF or DKIM result based on the sender domain's policy.
MIME_AUTH_DMARC_FAILED	The message failed DMARC evaluation. It did not pass SPF or DKIM checks in a way that aligns with the domain's published policy.
MIME_AUTH_TEMP_ERROR	A temporary error occurred while evaluating one or more authentication mechanisms. This may indicate a DNS lookup timeout or other transient failure.
MIME_AUTH_PERM_ERROR	A permanent error occurred during authentication checks. This may indicate a malformed DNS record or invalid message structure that prevents proper evaluation.

Remarks

Modern email systems use a set of authentication mechanisms to help verify that a message was sent from a legitimate source and not forged by a spammer or attacker. The **GetAuthenticationResults** method enables you to easily determine which of these mechanisms have passed a check and which of them have failed. It evaluates the following authentication information reported by the mail server:

SPF
Sender Policy Framework allows the owner of a domain to specify which mail servers are authorized to send email on its behalf. If the sending server is not listed in the domain's SPF record, the message may be marked as suspicious. SPF helps prevent spoofing of the envelope sender address, which is often used in phishing attacks.

DKIM
DomainKeys Identified Mail uses public-key cryptography to sign specific parts of the email, such as headers and body content. The signature is added by the sending mail server, and receiving systems use DNS to retrieve the sender's public key to verify that the message has not been tampered with. A valid DKIM signature helps confirm that the message was truly sent by the claimed domain.

DMARC
Domain-based Message Authentication, Reporting, and Conformance builds on SPF and DKIM by defining a policy for how a domain wants email receivers to handle messages that fail authentication checks. It also ensures that the visible From: address matches the domain that passed SPF or DKIM (a concept called alignment). DMARC allows domain owners to monitor abuse and enforce stronger protection against spoofing.

Checking these authentication results can help identify spoofed or forged messages, improve filtering decisions, and increase overall mail security. While not every legitimate message will have all three, failure of all mechanisms, especially from domains that publish strict DMARC policies, should be treated as suspicious.

While these authentication methods are useful signals, failing one of them does not necessarily mean a message is malicious. Many legitimate messages, even from well-known companies, may have misconfigured SPF records, missing DKIM signatures, or inconsistent DMARC policies. Conversely, a message that passes all checks could still be unwanted or deceptive. These results should be treated as advisory signals rather than absolute indicators of legitimacy. Developers are encouraged to consider authentication status alongside other factors, such as message content, sender reputation, and user reporting.

To simplify checking authentication outcomes, the following predefined flag combinations are also available:

- MIME_AUTH_PASSED is a combination of all passing results (SPF, DKIM, DMARC).
- MIME_AUTH_FAILED is a combination of all failing results.
- MIME_AUTH_ERROR is a combination of temporary or permanent errors.

For a simplified boolean check using these flags, see the **CheckAuthenticationResults** method.

Example

```
if (mailMessage.Open(lpszFileName))
{
    // Get the authentication results for the message
    DWORD dwAuthFlags = mailMessage.GetAuthenticationResults();

    // Check if any of the SPF, DKIM, or DMARC checks failed
    if (dwAuthFlags & MIME_AUTH_FAILED)
```

```
        _tprintf(_T("This message has failed one or more authentication
checks\n"));

    mailMessage.Close();
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

See Also

CMailMessage::GetBoundary Method

```
LPCTSTR GetBoundary();
```

The **GetBoundary** method returns a pointer to the boundary string used to separate the parts of a multipart message.

Parameters

None.

Return Value

If the method succeeds, the return value is a pointer to the boundary string. If the method fails, a NULL pointer is returned. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

CMailMessage::GetContentDigest Method

```
INT GetContentDigest(
   LPTSTR lpszDigest,
   INT cchDigest
);

INT GetContentDigest(
   CString& strDigest
);
```

The **GetContentDigest** method returns an encoded digest of the message.

Parameters

lpszDigest

Pointer to a string buffer to contain the MD5 digest for the specified message. An alternate form of this method accepts a **CString** object which will contain the digest when the method returns.

cchDigest

Maximum length of the digest string, in bytes.

Return Value

If the method succeeds, the return value is the length of the message digest string. A value of zero specifies that there is no MD5 digest for the current message. If the method fails, the return value is MIME_ERROR. To get extended error information, call **GetLastError**.

Remarks

This method returns the value of the Content-MD5 header field in the main body of the message. If the header exists, it contains the MD5 digest for the message as defined in RFC 1864.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CMailMessage::GetContentLength Method

```
LONG GetContentLength();
```

The **GetContentLength** method returns the size of the current message part content in bytes.

Parameters

None.

Return Value

If the method succeeds, the return value is the content length. If the method fails, the return value is MIME_ERROR. To get extended error information, call **GetLastError**.

Remarks

This function will return the size of the content in the current message part as the number of bytes and does not account for any Unicode conversion of text. Exercise caution when using this function to determine the size of the buffer that should be allocated for a method like **GetText**. You should always allocate enough memory to accommodate any potential text conversion and decoding which may occur.

If you need to know the actual length of the decoded text in the current message part, use the **GetTextLength** method. That method will return the number of characters (not bytes) in the message after they have been decoded and the text has been converted to Unicode.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

See Also

CMailMessage::GetContentType Method

```
INT GetContentType(
   INT nMessagePart,
   LPTSTR lpszSubType,
   INT cchSubType,
   LPTSTR lpszParams,
   INT cchParams
);

INT GetContentType(
   INT nMessagePart,
   LPTSTR lpszSubType,
   INT cchSubType,
);

INT GetContentType();
```

Parameters

nMessagePart

An integer value which specifies the message part. Message parts are zero-based with the part zero being the primary content and additional parts typically containing message content and file attachments. A value of MIME_CURRENT_PART (-1) specifies the content type for the current message part should be returned.

lpszSubType

A null-terminated string buffer that will receive the content subtype, such as "html" or "plain". This parameter may be NULL if the subtype is not required.

cchSubType

The maximum number of characters that can be copied into the ***lpszSubType*** buffer, including the terminating null character. If the buffer is too small, the method will return an error.

lpszParams

A null-terminated string buffer that will receive any parameters associated with the content type, such as `charset=utf-8`. This parameter may be NULL if parameters are not needed.

cchParams

The maximum number of characters that can be copied into the ***lpszParams*** buffer, including the terminating null character. If the buffer is too small, the method will return an error.

Return Value

The method returns an integer value that identifies the top-level media type for the current message part. This value may be one of the following predefined constants:

Value	Description
MIME_CONTENT_TEXT	Textual content (e.g.: text/plain, text/html)
MIME_CONTENT_IMAGE	Image content (e.g.: image/jpeg, image/png)
MIME_CONTENT_AUDIO	Audio content (e.g.: audio/mpeg)
MIME_CONTENT_VIDEO	Video content (e.g.: video/mp4)
MIME_CONTENT_APPLICATION	Application-specific data (e.g.: application/pdf)

MIME_CONTENT_MESSAGE	Embedded message (e.g.: message/rfc822)
MIME_CONTENT_MULTIPART	Multipart content (e.g.: multipart/alternative)
MIME_CONTENT_WIDETEXT	Extended text using wide character encoding
MIME_CONTENT_UNKNOWN	The content type is unknown or could not be determined

If the method fails, it returns MIME_ERROR. To retrieve extended error information, call **GetLastError**.

Remarks

The **GetContentType** method parses the `Content-Type` header of the current message part and returns the content type information in a normalized form. If requested, the subtype name and any optional parameters are copied to the caller-supplied buffers. This method eliminates the need for manual parsing of MIME headers and is useful for determining how message parts should be processed based on their media type. For example, consider a message part with:

```
Content-Type: text/html; charset=utf-8
```

This method will return `MIME_CONTENT_TEXT`, and optionally a subtype of `"html"`, and the parameter string `"charset=utf-8"`. If only the numeric media type is required for use in a `switch` or `if-then-else` statement, the content type and parameters buffers may be omitted or passed as `NULL`.

If you wish to determine if the content type for a message part matches a specific value, you can use the **IsContentType** method.

Example

```
TCHAR szSubType[32] = {0};
TCHAR szParams[64] = {0};

// Check if the current message part is plain text; szParams may
// contain the original character set used
INT nContentType = mailMessage.GetContentType(
                        MIME_CURRENT_PART,
                        szSubType, _countof(szSubType),
                        szParams, _countof(szParams));

if (nContentType == MIME_CONTENT_TEXT && lstrcmpiA(szSubType, "plain") == 0)
{
    // Get the size of the decoded/converted message text
    LONG cchMessage = mailMessage.GetText(NULL, 0);
    if (cchMessage < 1)
    {
        _tprintf(_T("Message part %d does not contain any text\n"), nMessagePart);
        return;
    }

    // Allocate a buffer for the message text on the heap
    LPTSTR pszMessage = (LPTSTR)malloc((cchMessage + 1) * sizeof(TCHAR));
    if (pszMessage == NULL) // Virtual memory exhausted
        return;

    // Copy the message contents to the buffer
    cchMessage = mailMessage.GetText(pszMessage, cchMessage + 1);
    if (cchMessage > 0)
    {
        // Write the contents of the message part to the console
```

```
        fwrite(pszMessage, sizeof(TCHAR), cchMessage, stdout);
        fflush(stdout);
    }

    // Free the memory allocated for our text buffer
    free(pszMessage);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

CMailMessage::GetDate Method

```
INT GetDate(
   LPTSTR lpszDate,
   INT nMaxLength,
   BOOL bLocalize
);

INT GetDate(
   CString &strDate,
   BOOL bLocalize
);
```

The **GetDate** method returns the current message date and time.

Parameters

lpszDate

A null-terminated string buffer which will contain the message date. This parameter cannot be NULL. An alternate version of this method accepts a reference to a **CString** object which will contain the date and time when the method returns.

nMaxLength

The maximum number of characters which can be copied into the string buffer, including the terminating null character. This parameter cannot be zero.

bLocalize

An optional boolean flag which specifies if the date and time should be localized for the current timezone. If this parameter is omitted, the date and time will not be localized.

Return Value

If the method succeeds, the return value the length of the date and time string, not including the terminating null character. If the method fails, it will return zero. To get extended error information, call **GetLastError**.

Remarks

The **GetDate** method copies the formatted date string into the buffer provided by the caller. If the message contains a valid `Date` or `Sent` header, the function retrieves and, if requested, localizes the date and time string before copying it to the specified buffer. The returned string always conforms to the standard format described in RFC 822. To convert this date string into a numeric value suitable for time calculations, use the **ParseDate** method.

Previous versions of this method returned a pointer to a string managed by the internal message context which could be invalidated or overwritten by subsequent operations. This version ensures the date string remains valid for the lifetime of the caller's buffer, avoiding issues with internal pointer reuse or invalidation that could occur in multithreaded or reentrant scenarios.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

CMailMessage::GetErrorString Method

```
INT GetErrorString(
   DWORD dwErrorCode,
   LPTSTR lpszDescription,
   INT nMaxLength
);
```

The **GetErrorString** method is used to return a description of a specific error code. Typically this is used in conjunction with the **GetLastError** method for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

The buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length.

nMaxLength

The maximum number of characters that may be copied into the description buffer.

Return Value

If the method succeeds, the return value is the length of the description string. If the method fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the method is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

CMailMessage::GetExportOptions Method

```
BOOL GetExportOptions(
   LPDWORD lpdwOptions
);
```

The **GetExportOptions** method returns a bitmask that describes the default message export options.

Parameters

lpdwOptions

Pointer to mask of attribute options. The mask is a combination of the following values:

Value	Description
MIME_OPTION_DEFAULT	The default export options. The headers for the message are written out in a specific consistent order, with custom headers written to the end of the header block regardless of the order in which they were set or imported from another message. If the message contains Bcc, Received, Return-Path, Status or X400-Received header fields, they will not be exported.
MIME_OPTION_KEEPORDER	The original order in which the message header fields were set or imported are preserved when the message is exported.
MIME_OPTION_ALLHEADERS	All headers, including the Bcc, Received, Return-Path, Status and X400-Received header fields will be exported. Normally these headers are not exported because they are only used by the mail transport system. This option can be useful when exporting a message to be stored on the local system, but should not be used when exporting a message to be delivered to another user.
MIME_OPTION_NOHEADERS	When exporting a message, the main header block will not be included. This can be useful when creating a multipart message for services which expect MIME formatted data, such as HTTP POST requests. This option should never be used for email messages being submitted using SMTP.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is 0. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CMailMessage::GetFileType Method

```
UINT GetFileType(
   LPCTSTR lpszFileName,
   LPTSTR lpszContentType,
   INT cchContentType
);

UINT GetFileType(
   LPCTSTR lpszFileName,
   CString& strContentType
);
```

The **GetFileType** method returns the content type for the specified file.

Parameters

lpszFileName

Pointer to a string which specifies the name of the file for which content type information is returned.

lpszContentType

Pointer to a string buffer that will contain the MIME type for the specified file. This may be a NULL pointer, in which case this parameter is ignored. If a buffer is provided, it is recommended that it be at least 64 characters in length.

cchContentType

An integer which specifies the maximum number of characters, including the terminating null character, which may be copied into the string buffer.

Return Value

If the method succeeds, the return value is the content type of the specified file. If the method fails, the return value is MIME_CONTENT_UNKNOWN. To get extended error information, call **GetLastError**.

The following values may be returned by this method:

Value	Description
MIME_CONTENT_UNKNOWN	The file content type is unknown. This value may be returned if the message handle is invalid, or if the file extension is unknown and the file could not be opened for read access.
MIME_CONTENT_APPLICATION	The file content is application specific. Examples of this type of file would be a Microsoft Word document or an executable program. This is also the default type for files which have an unrecognized file name extension and contain binary data.
MIME_CONTENT_AUDIO	The file is an audio file in one of several standard formats. Examples of this type of file would be a Windows (.wav) file or MPEG3 (.mp3) file.
MIME_CONTENT_IMAGE	The file is an image file in one of several standard formats. Examples of this type of file would be a GIF or JPEG image file.
MIME_CONTENT_TEXT	The file is a text file. This is also the default type for files which have an unrecognized file name extension and contain only

	printable text data.
MIME_CONTENT_VIDEO	The file is a video file in one of several standard formats. Examples of this type of file would be a Windows (.avi) or Quicktime (.mov) video file.

Remarks

The content type for a given file is determined based on the file name extension, or if the extension is not recognized, the actual contents of the file. On 32-bit platforms, the system registry is used to determine the default content type values for a given extension. In all cases, file types that are explicitly set using the **SetFileType** method will override the default system values.

The content type string which is copied to the string buffer is the standard MIME content type description, which specifies a primary type and a subtype, separated by a slash. For example, a plain text file would have a content type of text/plain, while an HTML document would have a content type of text/html. Binary files may be associated with a specific application. For example, the content type for a Microsoft Word document is application/msword. Those binary files which are not associated with a specific application, or have an unrecognized file name extension, have a content type of application/octet-stream.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

CMailMessage::GetFilteredText Method

```
LONG GetFilteredText(
   LPTSTR lpszFiltered,
   LONG nMaxLength,
   DWORD dwOptions
);
```

The **GetFilteredText** method returns the filtered contents of a HTML or plain text message.

Parameters

lpszFiltered

A null-terminated string buffer which will contain the filtered text when the method returns. This buffer must be large enough to contain all of the filtered content and a terminating null character. If this parameter is NULL, the filtered text will not be copied. This can be used to determine the amount of filtered text that would be returned. This can be used to determine how much memory should be allocated for the filtered text; however, remember to allocate additional space for the terminating null character.

nMaxLength

An integer which specifies the maximum number of characters which can be copied into the string buffer. If the maximum length is not large enough to store all of the filtered text and a terminating null character, the method will return an error. This value may be zero which indicates you want determine the length of the filtered text without copying any characters.

dwOptions

An unsigned integer which specifies one or more bit flags. which controls what content is filtered from the message. It may be one or more of the following values.

Value	Description
MIME_FILTER_DEFAULT	Perform default filtering which removes HTML markup and decodes HTML entities. No additional filtering of URLs or text is performed.
MIME_FILTER_REMOVE_QUERY	Remove query parameters from hyperlinks such as `?id=123`. Useful for stripping tracking information or session data.
MIME_FILTER_REMOVE_CREDENTIALS	Remove embedded user credentials in URLs such as `user:pass@example.com`, preventing obfuscation or accidental disclosure.
MIME_FILTER_REMOVE_LINKS	Remove all hyperlinks from the message content. This includes both anchor tags in HTML and plain text URLs.
MIME_FILTER_REMOVE_UNICODE	Strip all non-ASCII (Unicode) characters from the message. Use this when only 7-bit clean output is required.
MIME_FILTER_REJECT_LOCAL	Reject any link that refers to internal or local domains, including `.local`, `.lan`, and `localhost`.
MIME_FILTER_REJECT_IP	Reject links that use raw IP addresses instead of

	hostnames, such as `http://192.168.1.1`.
MIME_FILTER_REJECT_PUNYCODE	Reject hyperlinks using Punycode-encoded domain names, such as those with the `xn--` prefix. This helps prevent spoofing using visually similar characters.
MIME_FILTER_REJECT_HTTP	Reject any hyperlinks that use `http://` instead of the secure `https://` protocol.
MIME_FILTER_REJECT_UNSAFE	Reject links using unsafe schemes such as `file:`, `data:`, or `javascript:`. These links are excluded by default unless overridden.
MIME_FILTER_ALLOW_PUNYCODE	Explicitly permit Punycode domain names in URLs even when `MIME_FILTER_REMOVE_UNICODE` is specified. Use when legitimate IDN domains are expected.
MIME_FILTER_ALLOW_UNSAFE	Allow potentially unsafe schemes such as `file:` or `javascript:` in message content. Use with caution and only when the message source is fully trusted.
MIME_FILTER_ALLOW_SYMBOLS	Allow Unicode symbols such as emojis and pictographs in the filtered text.
MIME_FILTER_ALLOW_CONFUSABLES	Allow Unicode characters which can be confused with normal ASCII characters. Use only when the message source is fully trusted.

Return Value

The method will return the number of characters of filtered text copied to the string buffer, not including the terminating null character. If the *lpszFilteredText* parameter is NULL, the method will return the length of the filtered text without copying any characters. A return value of zero indicates the message part does not contain any message text. If the method fails it will return MIME_ERROR. To get extended error information, call **MimeGetLastError**.

Remarks

The **GetFilteredText** method filters MIME-encoded message parts by removing HTML tags and other potentially unsafe or undesired content. It handles both HTML and plain text content types. For HTML, the method converts the markup to plain text and decodes HTML entities. For plain text, it scans for embedded URLs and applies filtering based on the specified options.

When filtering HTML markup from message content, this method:

- Removes script, style, and other non-visible or unsafe elements.
- Converts common tag structures, such as lists and headers, into readable plain text.
- Extracts and optionally filters or removes hyperlinks and image alt text.
- Decodes common HTML entities such as `&trade` and `&copy`, as well as numeric entites like `&#x20.`
- Normalize Unicode characters to their canonical values (NKFD normalization).
- Replace confusable homoglyhs with their ASCII counterparts.

- Remove symbols such as emojis and pictographs which can confuse pattern matching.

The method is designed to produce clean, human-readable output suitable for previewing message contents in text-only environments, logging, or performing further analysis. It ensures that embedded credentials, tracking links, or insecure resources are removed or sanitized based on caller preferences.

By default, the method does not remove Unicode characters or strip links unless explicitly instructed via flags. The `MIME_FILTER_STRICT` constant is a recommended combination for maximum safety and removes potentially malicious or misleading elements from messages. Characters that are visually indistinguishable from standard Latin letters, such as the Cyrillic "a" (U+0430) and Latin "a" (U+0061), will be converted to their ASCII equivalent, preventing homoglyhph attacks and attempts to obsfucate links or defeat pattern matching.

To obtain the original message content, use the **GetText** method.

Example

```
// Search a multipart message for the HTML version of the message
// and write the filtered content to standard output

if (!mailMessage.Open(pszFileName))
{
    _tprintf(_T("Unable to open message %s\n"), pszFileName);
    return;
}

// Get the number of parts in the message
INT nPartCount = mailMessage.GetPartCount();

for (INT nMessagePart = 0; nMessagePart < nPartCount; nMessagePart++)
{
    // Set the current message part
    mailMessage.SetPart(nMessagePart);

    if (mailMessage.IsContentType(_T("text/html")))
    {
        DWORD dwOptions = MIME_FILTER_STRICT;

        // Determine the amount of memory we need to allocate
        LPTSTR pszFiltered = NULL;
        LONG cchFiltered = mailMessage.GetFilteredText(NULL, 0, dwOptions);

        if (cchFiltered < 1)
        {
            // Unable to filter this message part even though its identified
            // as containing HTML or it does not contain any text
            break;
        }
        else
        {
            // Allocate memory for the filtered text; note the extra space is
            // included for the terminating null character
            pszFiltered = (LPTSTR)malloc((cchFiltered + 1) * sizeof(TCHAR));

            if (pszFiltered == NULL)
            {
                // Unable to allocate memory for the filtered text
                break;
            }
```

```
            // Return the filtered message contents in pszFiltered
            cchFiltered = mailMessage.GetFilteredText(
                                pszFiltered,
                                cchFiltered + 1,
                                dwOptions);

            if (cchFiltered > 0)
            {
                // Write the filtered text to standard output on the console
                fwrite(pszFiltered, sizeof(TCHAR), cchFiltered, stdout);
            }

            // Free the memory we allocated for the filtered text
            free(pszFiltered);
            break;
        }
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

CMailMessage::GetFirstHeader Method

```
BOOL GetFirstHeader(
   LPTSTR lpszHeader,
   INT cchMaxHeader,
   LPTSTR lpszValue,
   INT cchMaxValue
);

BOOL GetFirstHeader(
   CString& strHeader,
   CString& strValue
);
```

The **GetFirstHeader** method returns the header field name and value for the first header in the current message part. This method is typically used in conjunction with **GetNextHeader** to enumerate all of the message header fields and their values in the current message part.

Parameters

lpszHeader

A null-terminated string buffer that will contain the name of the first header in the current message part. This parameter cannot be a NULL pointer.

cchMaxHeader

An integer which specifies the maximum number of characters which may be copied into the buffer, including the terminating null character. This parameter must have a value greater than zero.

lpszValue

A null-terminated string buffer that will contain the value of the first header in the current message part. This parameter may be a NULL pointer, in which case the value of the header field is ignored.

cchMaxValue

An integer which specifies the maximum number of characters which may be copied into the buffer, including the terminating null character. If the ***lpszValue*** parameter is NULL, this parameter should have a value of zero.

Return Value

If the method succeeds, the return value is non-zero. If no headers exist for the current message part, or the handle to the message is invalid, the method will return zero. To get extended error information, call **GetLastError**.

Remarks

Each part in a multipart message has one or more header fields. To obtain header values for the main message, rather than the message attachments, the current part number must be set to zero using the **SetPart** method.

The header fields from an imported message may not be returned in the same order as which they appear in the message. An application should never make an assumption about the order in which one or more header fields are defined.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

CMailMessage::GetHandle Method

```
HMESSAGE GetHandle();
```

The **GetHandle** method returns the message handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the message handle associated with the current instance of the class object. If there is no current message, the value INVALID_MESSAGE will be returned.

Remarks

This method is used to obtain the message handle created by the class for use with the SocketTools API.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

CMailMessage::GetHeader Method

```
INT GetHeader(
   INT nMessagePart,
   LPCTSTR lpszHeader,
   LPTSTR lpszValue,
   INT nMaxValue
);

INT GetHeader(
   LPCTSTR lpszHeader,
   LPTSTR lpszValue,
   INT nMaxValue
);

INT GetHeader(
   INT nMessagePart,
   LPCTSTR lpszHeader,
   CString& strValue
);

INT GetHeader(
   LPCTSTR lpszHeader,
   CString& lpszValue
);
```

The **GetHeader** copies the value of the specified header into a string buffer.

Parameters

nMessagePart

An integer value which specifies which part of the message to return the header value from. A value of zero returns a header value from the main message header, while a value greater than zero returns the header value from that specific part of a multipart message. A value of -1 specifies that the header value should be returned from the current message part. If this argument is omitted, the value will be returned from the current message part.

lpszHeader

A null-terminated string which specifies the message header.

lpszValue

A null-terminated string buffer which will contain the value of the specified header when the method returns. If this parameter is NULL, the method will return the length of the header value without copying the data. This is useful for determining the length of a header value so that a string buffer can be allocated and passed to a subsequent call to the method. In alternate forms of this method, a **CString** object may be specified which will contain the header field value when the method returns.

nMaxValue

An integer value which specifies the maximum number of characters that can be copied to the string buffer, including the terminating null character. If the ***lpszValue*** parameter is NULL, this value should be zero.

Return Value

If the method succeeds, the return value is the number of bytes copied into the string buffer, not including the terminating null byte. If the ***lpszValue*** parameter is NULL, the return value is the length

of the header value. If the header field does not exist, a value of zero is returned. If an invalid pointer or message part is specified, a value of MIME_ERROR is returned. To get extended error information, call **GetLastError**.

Example

```
CMailMessage *pMessage = new CMailMessage();
CString strSubject;

// Compose a test message
pMessage->Compose(_T("Bob Jones <bob@example.com>"),
                        _T("Tom Smith <tom@example.com>"),
                        NULL,
                        _T("This is a test message"),
                        _T("This is a test, this is only a test."));

// Change the subject of the message
if (pMessage->GetHeader(0, _T("Subject"), strSubject))
{
    strSubject = _T("Re: ") + strSubject;
    pMessage->SetHeader(0, _T("Subject"), strSubject);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CMailMessage::GetLastError Method

```
DWORD GetLastError();

DWORD GetLastError(
   CString& strDescription
);
```

Parameters

strDescription

A string which will contain a description of the last error code value when the method returns. If no error has been set, or the last error code has been cleared, this string will be empty.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **SetLastError** method. The Return Value section of each reference page notes the conditions under which the method sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **GetLastError** method immediately when a method's return value indicates that an error has occurred. That is because some methods call **SetLastError**(0) when they succeed, clearing the error code set by the most recently failed method.

Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_MESSAGE or MIME_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

The description of the error code is the same string that is returned by the **GetErrorString** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

See Also

CMailMessage::GetLinks Method

```
LONG GetLinks(
   LPTSTR lpszLinkList,
   LONG nMaxLength,
   LONG *lpnLinkCount
   DWORD dwLinkTypes,
);

LONG GetLinks(
   CString &strLinkList,
   LONG *lpnLinkCount
   DWORD dwLinkTypes,
);

INT GetLinks(
   CStringArray &arrLinks,
   DWORD dwLinkTypes
);

INT GetLinks(
   CSimpleArray<CString> &arrLinks,
   DWORD dwLinkTypes
);
```

The **GetLinks** method returns the hyperlinks in the current message part.

Parameters

lpszLinkList

A null-terminated string buffer which will contain all of the matching links found in the current message part. This buffer must be large enough to contain the entire list, including the terminating null character. If you wish to determine the number of characters required to store the list, this parameter can be NULL and the *nMaxLength* parameter should be zero. If you are dynamically allocating memory for the list, make sure you are including additional space for the terminating null. If multiple links are found in the message contents, each link will be separated with a single space. An alternate version of this method accepts a reference to a **CString** object if the project uses MFC or ATL.

arrLinks

An alternate version of this method accepts a reference to a **CStringArray** object in MFC or a **CSimpleArray** object in ATL. In this case, the list of links will be split and returned as a collection of **CString** objects. Note that this version of the method does not return the total length of the link list. Instead, it returns the number of links added to the array.

nMaxLength

The maximum number of characters which can be copied into the string buffer. The buffer must be large enough to store the complete list of links and the terminating null character. If this parameter is zero, the list of links are not copied to the buffer, but the method will return the number of characters required to store the complete list of links, not including the terminating null. If the *lpszLinkList* parameter is NULL, this parameter must be zero.

lpnLinkCount

A pointer to an optional integer which will contain the number of matching links extracted from the current message part. If this information is not required, this parameter can be NULL. This value will

be initialized to zero and updated with the link count if the method is successful.

dwLinkTypes

An unsigned integer value which specifies one or more bitflags which identify what types of links you would like to extract. To extract all supported link types, omit this parameter or use a value of **0**.

Value	Description
MIME_LINK_HTTP	Return standard **http://** links in the current message part.
MIME_LINK_HTTPS	Return secure **https://** links in the current message part.
MIME_LINK_FTP	Return standard **ftp://** links in the current message part.
MIME_LINK_FTPS	Return secure **ftps://** and **ftpes://** links in the current message part.
MIME_LINK_SFTP	Return secure **sftp://** links in the current message part.
MIME_LINK_FILE	Return local **file://** links in the current message part.

Return Value

If the method succeeds, the return value is the number of characters copied into the string buffer provided. If the *nMaxLength* parameter is zero, the return value specifies the number of characters required to store the list of links, not including the terminating null character. If you use this method to determine the required buffer size, allocate memory for the returned character count plus one additional character for the terminating null. If the method fails, it will return zero. To get extended error information, call the **GetLastError** method. The last error code will be set to NO_ERROR if the parameters are valid but there are no links found in the current message part.

If you use the version of this method which returns the list of links in a **CString** collection, the return value will be the number of links added to the collection. These versions of this method are only available to applications which are built with support for the Microsoft Foundation Classes (MFC) or Active Template Library (ATL).

Remarks

The **GetLinks** method enables you to obtain a list of the hyperlinks which are found in the current message part. The *dwLinkTypes* parameter allows you to specify the types of links you would like to extract. The message contents are decoded and converted to UTF-8 before searching for matching links. If the message content uses HTML markup, it is possible for this method to return links in the HTML header as well as the body. Messages which are composed using Outlook will typically have links to XML namespaces like **http://www.w3.org/TR/REC-html40**. You can omit these links by not including **MIME_LINK_HTTP** in the link type bitmask.

This method can only be used to extract links from message text and cannot be used with file attachments or encoded binary data. For example, if the current message part contains encoded image data, this method will return zero. This method ignores any links that use URL schemes not listed above, such as **mailto:** or **data:**. If you have a need to find a different type of link, you can use the **FindText** method to search the message using a regular expression that matches your specific requirements.

Example

```
if (!mailMessage.Open(TEST_HTMLMSG)
{
     // Unable to open the message file
```

```
     return;
}

// Get the number of parts in a multipart message; if there is only
// one part then this is an simple RFC 822 formatted message
INT nPartCount = mailMessage.GetPartCount();

for (INT nMessagePart = 0; nMessagePart < nPartCount; nMessagePart++)
{
    // Set the current message part
    mailMessage.SetPart(nMessagePart);

    // If this message part is not plain text or HTML, move to the next
    if (mailMessage.GetContentType() != MIME_CONTENT_TEXT)
        continue;

    // Populate an ATL CSimpleArray<CString> object with any links
    CSimpleArray<CString> arrLinks;
    INT nLinkCount = mailMessage.GetLinks(arrLinks, MIME_LINK_HTTPS);

    if (nLinkCount > 0)
    {
        _tprintf(_T("Message part %d has %d secure links\n"), nMessagePart,
nLinkCount);

        // Print each of the links in this message part
        for (INT nIndex = 0; nIndex < nLinkCount; nIndex++)
            _tprintf(_T("\tLink %d: %s\n"), nIndex + 1, (LPCTSTR)arrLinks[nIndex]);
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

CMailMessage::GetNextHeader Method

```
BOOL GetNextHeader(
   LPTSTR lpszHeader,
   INT cchMaxHeader,
   LPTSTR lpszValue,
   INT cchMaxValue
);

BOOL GetNextHeader(
   CString& strHeader,
   CString& strValue
);
```

The **GetNextHeader** method returns the header field name and value for the next header in the current message part. This method is typically used in conjunction with **GetFirstHeader** to enumerate all of the message header fields and their values in the current message part.

Parameters

lpszHeader

A null-terminated string buffer that will contain the name of the next header in the current message part. This parameter cannot be a NULL pointer.

cchMaxHeader

An integer which specifies the maximum number of characters which may be copied into the buffer, including the terminating null character. This parameter must have a value greater than zero.

lpszValue

A null-terminated string buffer that will contain the value of the next header in the current message part. This parameter may be a NULL pointer, in which case the value of the header field is ignored.

cchMaxValue

An integer which specifies the maximum number of characters which may be copied into the buffer, including the terminating null character. If the ***lpszValue*** parameter is NULL, this parameter should have a value of zero.

Return Value

If the method succeeds, the return value is non-zero. If no more headers exist for the current message part, or the handle to the message is invalid, the method will return zero. To get extended error information, call **GetLastError**.

Remarks

Each part in a multipart message has one or more header fields. To obtain header values for the main message, rather than the message attachments, the current part number must be set to zero using the **SetPart** method.

The header fields from an imported message may not be returned in the same order as which they appear in the message. An application should never make an assumption about the order in which one or more header fields are defined, with the following exception:

If an imported message has multiple Received headers, then those headers will be returned by **GetNextHeader** in the order in which they appeared in the original message. Note that if **GetHeader** is used to retrieve the Received header, the first Received header in the message will be returned.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

CMailMessage::GetPart Method

```
INT GetPart();
```

The **GetPart** method returns the current message part index for the specified message.

Parameters

None.

Return Value

If the method succeeds, the return value is the message part index. If the method fails, the return value is MIME_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

See Also

CreatePart, DeletePart, GetPartCount, SetPart

CMailMessage::GetPartCount Method

```
INT GetPartCount();
```

The **GetPartCount** method returns the total number of message parts for the specified message. Each message consists of at least one part.

Parameters

None.

Return Value

If the method succeeds, the return value is the number of message parts. If the method fails, the return value is MIME_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

See Also

CMailMessage::GetSender Method

```
INT GetSender(
   LPCTSTR lpszSender,
   INT nMaxLength
);

INT GetSender(
   CString& strSender
);
```

The **GetSender** method returns the email address of the message sender in the specified string buffer.

Parameters

lpszSender

A null-terminated string buffer that will contain the email address of the message sender when the method returns. In alternate forms of this method, a **CString** object may be specified which will contain the email address when the method returns.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied to the string buffer, including the terminating null character. It is recommended that the maximum length be at least 64 characters.

Return Value

If the method succeeds, the return value is the number of bytes copied to the string buffer. If an error occurs, the method will return MIME_ERROR. To get extended error information, call **GetLastError**.

Remarks

This method attempts to determine the email address of the sender that originated the message. It will first check for the presence of a Sender or X-Sender header value. If these headers are not defined, it will use the value of the From header field. It will only return successfully if a valid email address can be found.

If the method succeeds, the string buffer that is provided will only contain an email address. It will not contain the display name of the user associated with the address or any extraneous comments that are included in quotes or parenthesis.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

CMailMessage::GetSize Method

```
DWORD GetSize(
   DWORD dwOptions
);
```

The **GetSize** method returns the size of the complete message in bytes.

Parameters

dwOptions

An optional unsigned integer value which specifies how the size of the message should be calculated, based on what header fields should be included. These are the same options used when exporting a message to a file or memory buffer. The following values may be combined using a bitwise Or operator:

Value	Description
MIME_OPTION_DEFAULT	The default export options. The headers for the message are written out in a specific consistent order, with custom headers written to the end of the header block regardless of the order in which they were set or imported from another message. If the message contains Bcc, Received, Return-Path, Status or X400-Received header fields, they will not be exported.
MIME_OPTION_ALLHEADERS	All headers, including the Received, Return-Path, Status and X400-Received header fields will be exported. Normally these headers are not exported because they are only used by the mail transport system. This option can be useful when exporting a message to be stored on the local system, but should not be used when exporting a message to be delivered to another user.

Return Value

If the method succeeds, the return value is the size of the current message in bytes. If an error occurs, the method will return MIME_ERROR. To get extended error information, call **GetLastError**.

Remarks

This method returns the size of the complete message, including all headers, the message body and any attachments. It can be used to determine the minimum amount of memory that should be allocated to export the message to a memory buffer using the **Export** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

See Also

Export, GetText, GetTextLength, Import, SetExportOptions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CMailMessage::GetText Method

```
LONG GetText(
   LPTSTR lpszMessage,
   LONG nMaxLength,
   LONG nOffset
);

LONG GetText(
   CString& strMessage,
   LONG nOffset
);
```

The **GetText** method copies the text of the current message part to the specified buffer.

Parameters

lpszMessage

A null-terminated string buffer that will receive a copy of the message text when the method returns.

nMaxLength

The maximum number of bytes to copy into the buffer. The size of the buffer provided must be larger than the content length for the current message part.

nOffset

An optional parameter which specifies the byte offset from the beginning of the message. A value of zero specifies the first character in the body of the message part.

Return Value

If the method succeeds, the return value is number of bytes copied into the buffer. If the method fails, the return value is MIME_ERROR. To get extended error information, call **GetLastError**.

Remarks

If your project targets a multi-byte character set, this method will always return the message contents as UTF-8 text, regardless of the original character set specified in the message itself. This ensures that characters in the original text are preserved, regardless of the default ANSI code page on the local system. It is recommended you build your project to use Unicode whenever possible. If your application must use ANSI, you can use the **LocalizeText** method to convert the Unicode text to a specific character set.

You should not determine the maximum size of the output buffer using the **GetContentLength** method. That method returns the content size in bytes as it is stored in the message, and does not account for any character encoding or Unicode conversion which may be required. The content length can be used to estimate the amount of text stored in the message part, but you should always allocate a buffer which is larger than the length specified in the message. It is recommended you use the **GetTextLength** method to detemrine how large the string buffer should be.

If the *nMaxLength* parameter does not specify a buffer size large enough to store the contents of the current message part, this method will fail and the last error code will be set to ST_ERROR_BUFFER_TOO_SMALL. Your application must ensure the buffer is large enough to contain the complete message text and a terminating null character. If you wish to determine the actual length of the decoded message text, you can specify the *lpszMessage* parameter as NULL and *nMaxLength* as zero. This will cause the method to return the number of characters in the current message part,

not including the terminating null. When allocating a buffer on the heap, make sure you include additional space for the terminating null character. See the example below.

If the current message part contains HTML markup and you want to display it as plain text to the user, you can use the **GetFilteredText** method. It can remove markup from the message text, as well as remove potentially dangerous hyperlinks.

Example

```
if (mailMessage.GetContentType(hMessage) == MIME_CONTENT_TEXT)
{
    // Get the size of the decoded/converted message text
    LONG cchMessage = mailMessage.GetTextLength();
    if (cchMessage < 1)
    {
        _tprintf(_T("Message part %d does not contain any text\n"), nMessagePart);
        return;
    }

    // Allocate a string buffer for the message text +1 for the null character
    LPTSTR pszMessage = (LPTSTR)malloc((cchMessage + 1) * sizeof(TCHAR));
    if (pszMessage == NULL) // Virtual memory exhausted
        return;

    // Copy the message contents to the buffer
    cchMessage = mailMessage.GetText(pszMessage, cchMessage + 1);
    if (cchMessage > 0)
    {
        // Write the contents of the message part to the console
        fwrite(pszMessage, sizeof(TCHAR), cchMessage, stdout);
        fflush(stdout);
    }

    // Free the memory allocated for our text buffer
    free(pszMessage);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

CMailMessage::GetTextLength Method

```
LONG GetTextLength();
```

Parameters

None.

Return Value

This method returns the number of text characters in the current message part. If the current message part does not contain any text, the method will return zero. If the method fails it will return MIME_ERROR. To retrieve extended error information, call the **GetLastError** method.

Remarks

The **GetTextLength** method returns the actual length of the message text in the current message part. This value may be different than what is returned by the **GetContentLength** method, which returns the value of the content length in bytes, as specified in the message header. The **GetTextLength** method returns the number of characters (not bytes) in the message text after the contents have been decoded and converted to Unicode.

Example

```
if (mailMessage.GetContentType(hMessage) == MIME_CONTENT_TEXT)
{
    // Get the size of the decoded/converted message text
    LONG cchMessage = mailMessage.GetTextLength();
    if (cchMessage < 1)
    {
        _tprintf(_T("Message part %d does not contain any text\n"), nMessagePart);
        return;
    }

    // Allocate a buffer for the message text +1 for the null character
    LPTSTR pszMessage = (LPTSTR)malloc((cchMessage + 1) * sizeof(TCHAR));
    if (pszMessage == NULL) // Virtual memory exhausted
        return;

    // Copy the message contents to the buffer
    cchMessage = mailMessage.GetText(pszMessage, cchMessage + 1);
    if (cchMessage > 0)
    {
        // Write the contents of the message part to the console
        fwrite(pszMessage, sizeof(TCHAR), cchMessage, stdout);
        fflush(stdout);
    }

    // Free the memory allocated for our text buffer
    free(pszMessage);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

See Also

IsContentType, GetFilteredText, GetContentLength, GetHeader, GetText, SetPart

CMailMessage::Import Method

```
BOOL Import(
   LPCTSTR lpszFileName
);

BOOL Import(
   LPCTSTR lpszMessage,
   INT nLength
);
```

The **Import** method imports the message from a file or a string buffer in memory, replacing the current message contents.

Parameters

lpszFileName

A null-terminated string which specifies the name of the file that contains the message to be imported.

lpszMessage

A null-terminated string which contains the message to be imported.

nLength

An integer value which specifies the number of bytes to read from the string buffer. If this argument is -1, then the entire contents of the string up to the terminating null character will be imported.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method replaces the current contents of the message with the contents of the specified file or string buffer. The file must be a text file which uses the standard MIME message structure. It may contain multiple parts, including file attachments and alternative representations of the same message. This function cannot be used to open or parse messages stored in a binary format.

The maximum size of an individual message is 2 GiB (approximately 2 billion characters). This limitation is implemented as a safety check to prevent importing very large files or large blocks of memory which are unlikely to contain a valid MIME formatted message. Most services impose much lower limits on the maximum size of an individual mail message.

If another message was previously opened or created using the same class instance, the previous contents will be cleared prior to importing the new message. If you wish to preserve any changes made to the current message, use the **Export** method prior to calling this method.

The version of this method which accepts a file name is functionally similar to the **Open** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

Export, Open, ParseText

CMailMessage::IsContentType Method

```
BOOL IsContentType(
   LPCTSTR lpszContentType
);

BOOL IsContentType(
   INT nMessagePart,
   LPCTSTR lpszContentType
);
```

The **MimeIsContentType** method checks if the content type for the message matches the specified content type.

Parameters

hMessage

Handle to the message.

nMessagePart

An optional integer value which specifies which part of the message to compare against the content type. A value of zero returns compares the content type against the main message header, while a value greater than zero compares the content type against the content type for a specific part of a multipart message. If this parameter is omitted or a value of MIME_CURRENT_PART (-1) is specified, the content type will be compared against the current message part.

lpszContentType

Pointer to a string which specifies the content type to compare against. This parameter cannot be NULL and it must specify a valid MIME media type. It is permitted to omit the media subtype, in which case the content type match will only be made against the base type. For example, both `"application/pdf"` and `"application"` are permitted as valid content types. Note that this is a prefix match, not a wildcard pattern match.

Return Value

The method will return a non-zero value if the specified content type matches the content type for the message part. If the content types do not match or one of the parameters is invalid, the method will return zero. To get extended error information, call **GetLastError**. If the parameters are valid but the content types do not match, the last error code will be set to NO_ERROR.

Remarks

The **IsContentType** method is used to check the content type for a specific part of a MIME-encoded message against a known media type. Multipurpose Internet Mail Extensions (MIME) defines a standard way of classifying the content of an email message or its individual parts, such as plain text, HTML, images, or file attachments.

A MIME media type, also referred to as a content type, is typically expressed in the form `type/subtype`. For example, the content type `text/plain` identifies unformatted plain text, while `text/html` identifies HTML formatted text. The content type for each message part is typically specified in its `Content-Type` header field. This method performs a case-insensitive comparison between the message part's declared content type and the type provided by the caller. It does not consider optional parameters, such as character encoding or boundary markers. For example, a content type of `"text/html; charset=UTF-8"` will match `"text/html"`.

The following table lists some of the most common MIME media types used in email messages:

Media Type	Description
`text/plain`	Plain text with no formatting
`text/html`	HTML-formatted text, commonly used for rich email content
`multipart/alternative`	Message that contains multiple representations of the same content, such as both plain text and HTML
`multipart/mixed`	Message that includes a combination of text and attachments
`multipart/related`	Message that includes related resources, such as inline images referenced by HTML content
`image/jpeg`	JPEG image
`image/png`	PNG image
`application/pdf`	PDF document
`application/octet-stream`	Generic binary data, typically used for file attachments

To obtain the full content type string for a message part, including any optional parameters, use the **GetHeader** method with the header name `"Content-Type"`.

Example

```
// Search the message for a PDF attachment by checking the content type
// for each part of a multipart message.
//
// If the content type matches "application/pdf" then that message part
// should contain a PDF attachment. We prompt the user where to store
// the file and then exit the loop.

INT nParts = mailMessage.GetPartCount();

for (INT nMessagePart = 1; nMessagePart < nParts; nMessagePart++)
{
    if (mailMessage.SetPart(nMessagePart) == MIME_ERROR)
        break;

    if (mailMessage.IsContentType(_T("application/pdf")))
    {
        TCHAR szAttachment[MAX_PATH] = _T("");

        // Get the name of the file attached to the message. This can be
        // useful for display purposes, but exercise caution if you want
        // to use that name to store the file locally.
        if (mailMessage.GetAttachedFileName(szAttachment, MAX_PATH))
        {
            _tprintf(_T("Found attachment \"%s\" in part %d\n"), szAttachment,
nMessagePart);

            // The recommended approach is to prompt your user for where
            // they would like you to store store the file attachment;
            // avoid using the remote filename directly without validating
            // or prompting the user.
            TCHAR szLocalFile[MAX_PATH] = _T("");

            OPENFILENAME ofn = {0};
```

```
            ofn.lStructSize = sizeof(OPENFILENAME);
            ofn.hwndOwner = NULL; // No owner window
            ofn.lpstrFilter = "Text Files (*.txt)\0*.txt\0All Files (*.*)\0*.*\0";
            ofn.lpstrFile = szLocalFile;
            ofn.nMaxFile = MAX_PATH;
            ofn.lpstrTitle = "Select File to Save";
            ofn.Flags = OFN_OVERWRITEPROMPT;

            // If the user cancels the dialog, we are finished
            if (!GetSaveFileName(&ofn))
                 break;

            // Extract the attachment to the file name specified by the user
            if (!mailMessage.ExtractFile(szLocalFile))
            {
                DWORD dwError = mailMessage.GetLastError();
                _tprintf(_T("Failed to extract file (Error 0x%08lX)\n"), dwError);
            }
        }
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

CMailMessage::IsInitialized Method

```
BOOL IsInitialized();
```

The **IsInitialized** method returns whether or not the class object has been successfully initialized.

Return Value

This method returns a non-zero value if the class object has been successfully initialized. A return value of zero indicates that the runtime license key could not be validated.

Remarks

When an instance of the class is created, the class constructor will attempt to initialize the component with the runtime license key that was created when SocketTools was installed. If the constructor is unable to validate the license key the initialization will fail.

If SocketTools was installed with an evaluation license, the application cannot be redistributed to another system. The class object will fail to initialize if the application is executed on another system, or if the evaluation period has expired. To redistribute your application, you must purchase a development license which will include the runtime key that is needed to redistribute your software to other systems. Refer to the Developer's Guide for more information.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

CMailMessage::LocalizeText Method

```
LONG LocalizeText(
   LPCTSTR lpszInput,
   LONG cchInput,
   LPBYTE lpOutput,
   LONG cbOutput,
   UINT nCharacterSet
);
```

The **LocalizeText** method converts a Unicode string to its ANSI equivalent using the specified character set.

Parameters

lpszInput

A null-terminated string which contains the Unicode text which should be localized. If the ANSI version of this function is called, the input text must be in UTF-8 format or the function will fail. This parameter cannot be a NULL pointer.

cchInput

An integer value which specifies the number of characters of text in the input string which should be localized. If this value is -1, the entire length of the string up to the terminating null will be decoded.

lpOutput

A buffer which will contain the localized ANSI version of the input text. This parameter cannot be a NULL pointer.

cbOutput

An integer value which specifies the maximum number of bytes which can be copied into the output buffer. The buffer must be large enough to store all of the localized text. This value must be greater than zero.

nCharacterSet

An optional numeric identifier which specifies the character set to use when localizing the text. If this parameter is omitted, the locale for the current thread will be used when localizing the text.

Return Value

If the input text can be successfully localized, the return value is the number of bytes copied into the output buffer. If the function returns zero, then no text was localized. If the function fails, the return value is MIME_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **LocalizeText** method enables the application to localize a Unicode string, returning the ANSI version of that text using the specified character set. Because library handles all text as Unicode internally, the ANSI functions in this library will always return UTF-8 encoded text. This method allows you to easily convert that UTF-8 text to another supported character set.

If the ANSI version of this function is called, the input text must use UTF-8 character encoding or the method will fail with the last error set to ST_ERROR_INVALID_CHARSET.

If the *nCharacterSet* parameter is MIME_CHARSET_DEFAULT or MIME_CHARSET_UNKNOWN the input text will be converted to the default ANSI code page for the current thread locale. If there are characters in the Unicode input text which cannot be converted to an ANSI equivalent using the

specified character set, those characters will be replaced by the default character for your locale, typically a question mark symbol. You cannot specify MIME_CHARSET_UTF16 as the character set.

This method will always attempt to ensure that the output buffer is terminated with an extra null byte so it is easier to work with as a standard C-style null-terminated string. However, if the output buffer is not large enough to accommodate the extra null byte, it will not be copied. It is always recommended that your output buffer be somewhat larger than the length of the original input text to account for multi-byte character sequences. If the output buffer is not large enough to contain the entire localized text, no bytes will be copied to the output buffer and the function will fail with the last error set to ST_ERROR_BUFFER_TOO_SMALL.

This function is only required if your application needs to localize the UTF-8 text returned by another function and convert it to a specific 8-bit ANSI character set. For example, if you have an application which calls the ANSI version of **MimeGetMessageText**, it will return the message contents as UTF-8 text. If you need to display that text as localized ANSI, you can call this function to convert the UTF-8 text to your current locale or a specific character set.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

CMailMessage::NormalizeText Method

```
LONG NormalizeText(
   LPCTSTR lpszInput,
   LONG cchInput,
   LPTSTR lpszOutput,
   LONG nMaxLength
);

LONG NormalizeText(
   LPCTSTR lpszInput,
   LONG cchInput,
   CString& strOutput
);
```

The **NormalizeText** method normalizes the input text to replace confusable Unicode homoglyphs, remove symbols and trim whitespace.

Parameters

lpszInput

A null-terminated string which contains the Unicode text that will be normalized. The input may only contain text and cannot include non-printable control characters. If this parameter is NULL or if the input contains binary data, this method will fail. If the ANSI version of this method is called, the input string must be contain ASCII or UTF-8 encoded Unicode characters.

cchInput

An integer which specifies the number of characters in the input string. If this parameter is -1, the length of the string will be determined by counting the number of characters up to a terminating null character.

lpszOutput

A null-terminated string buffer which will contain the normalized text. The buffer must be large enough to contain the entire string and a terminating null character or the method will fail. If this parameter is NULL and the ***nMaxLength*** parameter is zero, the method will return the number of characters required to store the normalized text, not including the terminating null character. An alternate version of this method accepts a reference to a **CString** object which will contain the normalized text when the method returns.

nMaxLength

The maximum number of characters which can be copied into the ***lpszOutput*** string buffer. If this value is zero, no characters will be copied to the output buffer and the method will return the length of the filtered output, not including the terminating null character. This can be used to determine how much memory should be allocated to store the filtered text.

Return Value

If the method succeeds, it will return the number of characters copied into the output buffer, not including the terminating null character. If the ***lpszOutput*** parameter is NULL and ***nMaxLength*** is zero, the method will return the number of characters in the filtered text, not including the terminating null. If the method fails, or there is no text in the input buffer, the method will return zero.

Remarks

The **NormalizeText** method performs a multi-stage normalization and cleanup of Unicode text, intended to simplify and standardize input that may contain visually similar (confusable) characters,

diacritical marks, or inconsistent whitespace. It applies NFKD (Compatibility Decomposition) normalization converting characters into their canonical forms and then replaces any confusable Unicode characters with their ASCII equivalents based on an internal mapping table. This method is similar to calling the **NormalizeString** function in the Windows API, however it performs additional checks and is more strict with how the input is validated.

If your project is configured to use a multibyte character set (ANSI), the input string is checked to ensure that it only contains valid UTF-8 encoding and will reject strings which contain invalid sequences. For example, it will reject multibyte UTF-8 sequences which are over-long or truncated, invalid continuation sequences or characters outside of valid Unicode code points. You should never provide a localized ANSI string composed using the current code page. If you wish to normalize a localized string, you should convert it to Unicode using the **MultiByteToWideChar** function and then call the Unicode version of this function.

If your project is configured to use Unicode, the input string is validated to ensure that it only contains valid UTF-16 encoding and will reject strings which contain invalid sequences. This includes checking to ensure there are no unpaired surrogates, invalid code points, unprintable control characters or private-use characters in the string. If the input string does not contain valid Unicode character sequences, the method will return zero and the last error code will be set to ST_ERROR_INVALID_UNICODE.

This method helps mitigate issues with characters that are visually indistinguishable from standard Latin letters, such as using the Cyrillic "a" (U+0430) instead of the Latin "a" (U+0061). It also removes symbols (such as emojis, flags and pictographs) which can confuse pattern matching and removes combining marks that can be used to visually modify characters or obscure text. Unicode whitespace is trimmed from both ends of the string, including zero-width and non-breaking spaces.

This method is particularly useful in security-sensitive applications where input normalization is critical, such as sanitizing user-provided domain names, filenames, or login credentials to prevent spoofing, phishing, or bypassing filters through the use of homoglyphs or invisible characters.

If you want a normalized version of the text in a message, you can use the **GetFilteredText** method. It performs many of the same normalizations that this method does, but allows for more flexibility through options which allow you to control how the message text is processed and filtered. It is particularly useful for filtering extraneous HTML from the message, enabling you to display a version of the message that is safer for the user (such as removing unsafe links from the message contents).

This method is deliberately biased toward security rather than readability and can affect the output when applied to text containing legitimate non-Latin characters. It is intended for use on text that is expected to contain only printable ASCII characters. For example, it will filter and normalize text containing certain Greek or Cyrillic characters that could be used to spoof ASCII letters or URL delimiters. While this helps mitigate obfuscated or malicious content, it can also make legitimate text in other languages unreadable.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

CMailMessage::Open Method

```
BOOL Open(
   LPCTSTR lpszFileName,
   DWORD dwOptions
);
```

The **Open** method opens and reads the specified file.

Parameters

lpszFileName

Pointer to a string which specifies the name of the text file to open. This parameter cannot be NULL.

dwOptions

An integer which specifies options for opening the message file. This parameter is reserved for future use and can be omitted. If specified, it should always be zero in the current implementation.

Value	Description
MIME_OPEN_DEFAULT	The default mode for opening the message file. Currently, this is the only option which should be specified.

Return Value

If the method succeeds, the return value is non-zero. If the method fails it returns zero. To get extended error information call the **GetLastError** method.

Remarks

This method opens the specified file, reads the contents into memory and then parses the message. The file must be a text file which uses the standard MIME message structure. It may contain multiple parts, including file attachments and alternative representations of the same message. This function cannot be used to open messages stored in a binary format.

If the file path includes environment variables enclosed in percentage (%) symbols, those values will be expanded based on the environment variables defined for the current user using the **ExpandEnvironmentStrings** function in the Windows API. Note that environment variable names are not case-sensitive.

The maximum size of an individual message is 2 GiB (approximately 2 billion characters). This limitation is implemented as a safety check to prevent opening very large files which are unlikely to contain a valid MIME formatted message. Most services impose much lower limits on the maximum size of an individual mail message.

Note: This method can only be used to open and parse messages structured according to the MIME (Multipurpose Internet Mail Extensions) standard, such as plain text `.eml` or `.txt` files. It cannot open messages stored in proprietary or binary formats used by certain email clients. For example, it does not support Microsoft Outlook message files such as `.msg` or mailbox files like `.pst` and `.ost`, nor does it support formats used by other clients such as Thunderbird's `.msf` (mail summary files) or the mbox family (`.mbx`, `.mbox`) when stored as binary containers. Attempting to open these file types will result in an error. If you need to work with messages exported from Outlook or other proprietary clients, first save or export them in the standard text format before using this method.

If another message was previously opened or created using the same class instance, the internal handle which references the previous message will be closed. If you wish to preserve any changes

made to the current message, use the **Export** method prior to calling this method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

CMailMessage::ParseAddress Method

```
INT ParseAddress(
   LPCTSTR lpszString,
   LPCTSTR lpszDomain,
   LPTSTR lpszAddress,
   INT nMaxLength
);

INT ParseAddress(
   LPCTSTR lpszString,
   LPTSTR lpszAddress,
   INT nMaxLength
);

INT ParseAddress(
   LPCTSTR lpszString,
   CString& strAddress
);
```

The **ParseAddress** method parses a string for an email address, copying the address to the specified buffer.

Parameters

lpszString

A null-terminated string which contains the email address to parse.

lpszDomain

A null-terminated string which specifies a default domain for the address. This parameter may be NULL or point to an empty string if no default domain is required.

lpszAddress

A null-terminated string buffer which will contain the parsed email address when the method returns. It is recommended that this buffer be at least 128 characters in length.

nMaxLength

The maximum number of characters which can be copied into the string buffer, including the terminating null character.

Return Value

If the method succeeds, the return value is the length of the address. If the method fails, the return value is MIME_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **ParseAddress** method is useful for parsing the email addresses that may be specified in various header fields in the message. In many cases, the addresses have additional comment characters which are not part of the address itself. For example, one common format used is as follows:

"User Name" <user@domain.com>

In this case, the email address is enclosed in angle brackets and the name outside of the brackets is considered to be a comment which is not part of the address itself. Another common format is:

user@domain.com (User Name)

In this case, there is the address followed by a comment which is enclosed in parenthesis. The

ParseAddress method recognizes both formats, and when passed either string, would return the following address:

user@domain.com

If there was no domain specified in the address, that is just a user name was specified, then the value the ***lpszDomain*** parameter is added to the address.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

CMailMessage::ParseDate Method

```
BOOL ParseDate(
   LPCTSTR lpszDate,
   LONGLONG *lpnSeconds,
   LONG *lpnTimezone,
   BOOL bLocalize
);

BOOL ParseDate(
   LPCTSTR lpszDate,
   LONG *lpnSeconds,
   LONG *lpnTimezone,
   BOOL bLocalize
);
```

The **ParseDate** method parses a date string, returning the number of seconds since 1 January 1970 and the difference in seconds between the specified timezone and coordinated universal time. If the string does not specify a timezone, the local timezone is used.

Parameters

lpszDate

A null-terminated string which specifies the date to be parsed. The date string must be in the standard format defined by RFC 822.

lpnSeconds

A pointer to a 64-bit or 32-bit integer which is set to the number of seconds since 1 January 1970 00:00:00 UTC. This date is commonly called the epoch, and is the base date used by the standard C/C++ time methods. This pointer may be NULL, in which case the parameter is ignored. It is recommended you always use the version which accepts a pointer to a 64-bit integer.

lpnTimezone

A pointer to a 32-bit integer which is set to the difference in seconds between the specified date's timezone and coordinated universal time (also known as Greenwich Mean Time). This pointer may be NULL, in which case the parameter is ignored.

bLocalize

A boolean flag which determines if the date should be localized to the current timezone, regardless of the timezone specified in the date string. A non-zero value specifies the timezone for the local system will be used, adjusted for daylight savings time if applicable.

Return Value

If the date could be successfully parsed, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method is not a general purpose date parsing function, and may not be capable of parsing dates for a specific locale. The date and time should be in a standard format as outlined in RFC 822, which describes the basic structure of Internet email messages. For a description of the date string format, refer to the **FormatDate** method.

If the date and time does not include any timezone information, Coordinated Universal Time (UTC) will be used by default. This is an important consideration if you use this function to parse input from a

user, because in most cases they will not provide a timezone and will assume the date and time they enter is for their current timezone.

The value of the ***bLocalize*** parameter will only change the number of seconds offset by the current timezone and does not affect the value returned in the ***lpnSeconds*** parameter. If the date is localized, the timezone offset will be adjusted for daylight savings if it was in effect at the time.

Developers are strongly encouraged to use the version of this function which expects a 64-bit integer to represent the number of seconds since the epoch. The version which uses a 32-bit integer limits the representable range to dates before 19 January 2038 (the so-called "Year 2038 problem"). After this date, 32-bit time values will overflow, resulting in incorrect date calculations and potential failures in software that processes email message dates. By contrast, the 64-bit integer value matches the standard `time_t` type used by modern C/C++ libraries. This not only eliminates the Year 2038 limitation but also ensures compatibility with current and future systems, allowing correct handling of dates both far in the past and well into the future. Whenever possible, applications should transition to the 64-bit version of this method to ensure long-term reliability and portability.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CMailMessage::ParseHeader Method

```
BOOL ParseHeader(
   LPCTSTR lpszHeader
);
```

The **ParseHeader** method parses a line of text and adds the header and value to the current message.

Parameters

lpszHeader

Pointer to a string which contains the header and value to be added to the message.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method is used to parse a line of text that is part of a message header. The string must consist of a header name, followed by a colon, followed by the header value. The header name may only consist of printable characters, and may not contain whitespace (space, tab, carriage return or linefeed characters).

In most cases, it is recommended you use the **SetHeader** method to set the value of a header.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CMailMessage::ParseText Method

```
BOOL ParseText(
   LPCTSTR lpszText,
   INT cchText
);
```

The **Parse** method parses the contents of the specified buffer and adds the contents to the message.

Parameters

lpszText

Pointer to a string buffer which contains the text to be added to the message contents.

cchText

The length of the specified buffer. If this value is -1 all of the characters in the string will be parsed up to the terminating null character.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method is useful when the application needs to parse an arbitrary block of text and add it to the specified message. If the string contains header fields, the values will be added to the message header. Once the end of the header block is detected, all subsequent text is added to the body of the message.

To open and parse a text file which contains a MIME structured email message, use the **Open** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CMailMessage::SetDate Method

```
BOOL SetDate(
   LPCTSTR lpszDate,
   BOOL bLocalize
);
```

The **SetDate** method sets the date and time in the header for the specified message.

Parameters

lpszDate

Pointer to a string which specifies the date and time. If this parameter specifies a zero-length string or a NULL pointer, the current date and time will be used.

bLocalize

Boolean flag that specifies the date and time should be localized for the current timezone.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The date string should be in a standard format as outlined in RFC 822, the document which describes the basic structure of Internet email messages. For a description of the date string format, refer to the **FormatDate** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CMailMessage::SetExportOptions Method

```
BOOL SetExportOptions(
   DWORD dwOptions
);
```

The **SetExportOptions** method specifies a bitmask that describes current message export options.

Parameters

dwOptions

Mask of attribute options. The mask is a combination of the following values:

Value	Description
MIME_OPTION_DEFAULT	The default export options. The headers for the message are written out in a specific consistent order, with custom headers written to the end of the header block regardless of the order in which they were set or imported from another message. If the message contains Bcc, Received, Return-Path, Status or X400-Received header fields, they will not be exported.
MIME_OPTION_KEEPORDER	The original order in which the message header fields were set or imported are preserved when the message is exported.
MIME_OPTION_ALLHEADERS	All headers, including the Bcc, Received, Return-Path, Status and X400-Received header fields will be exported. Normally these headers are not exported because they are only used by the mail transport system. This option can be useful when exporting a message to be stored on the local system, but should not be used when exporting a message to be delivered to another user.
MIME_OPTION_NOHEADERS	When exporting a message, the main header block will not be included. This can be useful when creating a multipart message for services which expect MIME formatted data, such as HTTP POST requests. This option should never be used for email messages being submitted using SMTP.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

By default, the Received and Return-Path headers are not exported. In addition, the order of the headers in an exported message is undefined. This is reasonable behavior for most mail clients, but may not be appropriate for applications which need access to all of the header fields.

Example

```
pMessage->SetExportOptions(MIME_EXPORT_OPTIONS_ALL |
                           MIME_EXPORT_OPTIONS_KEEP_ORDER);
```

```
if (pMessage->Import(lpszFileName))
{
    // Process the message and make any modifications
    // then write the message back out, preserving all
    // of the headers in their original order
    bResult = pMessage->Export(lpszFileName);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

Export, Import, GetExportOptions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CMailMessage::SetFileType Method

```
BOOL SetFileType(
   UINT nContentType,
   LPCTSTR lpszSubtype,
   LPCTSTR lpszExtension
);
```

The **SetFileType** method associates a per-message content type with a given file name extension. This association is specific to the message, and is not shared by an other messages that may be opened by the process.

Parameters

nContentType

An identifier which specifies the primary content type. It may be one of the following values:

Value	Description
MIME_CONTENT_UNKNOWN	The default content type for the specified extension should be used. This value should only be used to delete a previously defined content type.
MIME_CONTENT_APPLICATION	The file content is application specific. Examples of this type of file would be a Microsoft Word document or an executable program. This is also the default type for files which have an unrecognized file name extension and contain binary data.
MIME_CONTENT_AUDIO	The file is an audio file in one of several standard formats. Examples of this type of file would be a Windows (.wav) file or MPEG3 (.mp3) file.
MIME_CONTENT_IMAGE	The file is an image file in one of several standard formats. Examples of this type of file would be a GIF or JPEG image file.
MIME_CONTENT_TEXT	The file is a text file. This is also the default type for files which have an unrecognized file name extension and contain only printable text data.
MIME_CONTENT_VIDEO	The file is a video file in one of several standard formats. Examples of this type of file would be a Windows (.avi) or Quicktime (.mov) video file.

lpszSubtype

A null-terminated string which specifies the MIME subtype. This parameter may be NULL if the content type association is being deleted.

lpszExtension

A null-terminated string which specifies the file name extension that will be associated with the MIME content type.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To

get extended error information, call **GetLastError**.

Remarks

The **SetFileType** method allows an application to specify a content type for a given file extension, and is typically used to define custom content types for file attachments. The content type will override any default content types associated with the extension, as well as allow new content types to be defined for application-specific files.

Example

In the following example, the file extension ".dat" is associated with a custom content type, a file is attached to the message and then the custom content type is deleted. Note that because the primary content type designates the file as an application specific (non-text) file, it will be automatically encoded when attached to a message:

```
bResult = pMessage->SetFileType(
    MIME_CONTENT_APPLICATION,
    _T("octet-stream"), _T("dat"));

if (bResult)
{
    bResult = pMessage->AttachFile(lpszFileName, MIME_ATTACH_DEFAULT);
    pMessage->SetFileType(MIME_CONTENT_UNKNOWN, NULL, _T("dat"));
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

AttachData, AttachFile, GetFileType

CMailMessage::SetHeader Method

```
BOOL SetHeader(
   INT nMessagePart,
   LPCTSTR lpszHeader,
   LPCTSTR lpszValue
);

BOOL SetHeader(
   LPCTSTR lpszHeader,
   LPCTSTR lpszValue
);
```

The **SetHeader** method adds or updates a header field in the specified message.

Parameters

nMessagePart

An integer value which specifies which part of the message the header should be set or modified in. A value of zero sets a header value in the main message header block, while a value greater than zero sets the header value in that specific part of a multipart message. If this argument is omitted or a value of -1 is specified, the header value will be set in the current message part.

lpszHeader

Pointer to a string which specifies the header field that will be added or updated.

lpszValue

Pointer to a string which specifies the value for the header field. This pointer may be NULL, which causes the header field to be removed from the message.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CMailMessage::SetLastError Method

```
VOID SetLastError(
   DWORD dwErrorCode
);
```

The **SetLastError** method sets the last error code for the current thread. This method is typically used to clear the last error by specifying a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_MESSAGE or MIME_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

Applications can retrieve the value saved by this method by using the **GetLastError** method. The use of **GetLastError** is optional; an application can call the method to determine the specific reason for a method failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

See Also

GetErrorString, GetLastError, ShowError

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CMailMessage::SetPart Method

```
INT SetPart(
   INT nNewPart
);
```

The **SetPart** method sets the current message part index for the specified message.

Parameters

nNewPart

The new message part index. A value of zero specifies the main message part.

Return Value

If the method succeeds, the return value is the previous message part index. If the method fails, the return value is MIME_ERROR. To get extended error information, call **GetLastError**.

Remarks

Multipart email messages are structured using the MIME (Multipurpose Internet Mail Extensions) standard, which allows a single email to contain multiple content types, such as plain text, HTML, and file attachments, within a single message body. These components are organized as discrete parts, each with its own headers and body, separated by unique MIME boundaries. In a typical `multipart/alternative` message, part 0 often contains the message preamble (e.g.: "This is a multipart message in MIME format"), part 1 may contain the plain text version of the message, and part 2 may contain the HTML version. However, multipart messages are not required to include both plain text and HTML content. A message may only include an HTML part and one or more attachments, or any other combination of content types. The structure and ordering of parts depends entirely on how the original sender or mail client composed the message.

To simplify navigating these multipart structures, the **SetPart** and **GetPart** methods enable you to iterate through the individual parts of a message. The message parts are zero-based, with index 0 always referring to the top-level message headers and preamble. By calling **SetPart**, you can change the currently selected message part, enabling functions like **GetHeader** or **GetText** to operate on that specific segment. Calling **GetPart** returns the current part index, which can be useful for saving and restoring state while iterating over a message.

The internal MIME parser flattens multipart messages, meaning that if a message contains nested multipart sections (such as a multipart/mixed part containing a multipart/alternative part), all leaf parts are presented in a linear sequence. This simplifies access and avoids the complexity of recursive traversal. You can determine the total number of parts using **GetPartCount**, and then iterate from part 0 to part N-1 to examine or extract each segment in order. This approach provides both fine-grained access to MIME message parts and an intuitive model for parsing even complex message structures.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetPart, GetPartCount, SetHeader

CMailMessage::SetText Method

```
LONG SetText(
   LONG nOffset,
   LPCTSTR lpszText
);

LONG SetText(
   LPCTSTR lpszText
);
```

The **SetText** method copies the specified text into the body of the current message part.

Parameters

nOffset

The offset into the body of the message part. A value of -1 specifies that the text will be appended to the message body. If this argument is omitted, the current message text is replaced with the contents of the *lpszText* argument.

lpszText

A null-terminated string which specifies the text to be copied to the current message part at the given offset.

Return Value

If the method succeeds, the return value is the number of bytes copied into the message. A return value of zero indicates that no text could be copied into the current message part. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

AppendText, Clear, ClearText, CompareText, GetText, SetHeader, SetPart

CMailMessage::ShowError Method

```
INT ShowError(
   LPCTSTR lpszAppTitle,
   UINT uType,
   DWORD dwErrorCode
);
```

The **ShowError** method displays a message box which describes the specified error.

Parameters

lpszAppTitle

A null-terminated string which specifies the title of the message box that is displayed. If this argument is NULL or omitted, then the default title of "Error" will be displayed.

uType

An unsigned integer which specifies the type of message box that will be displayed. This is the same value that is used by the **MessageBox** method in the Windows API. If a value of zero is specified, then a message box with a single OK button will be displayed. Refer to that method for a complete list of options.

dwErrorCode

Specifies the error code that will be used when displaying the message box. If this argument is zero, then the last error that occurred in the current thread will be displayed.

Return Value

If the method is successful, the return value will be the return value from the **MessageBox** function. If the method fails, it will return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

CMailMessage Character Sets

Value	Name	Code Page	Description
MIME_CHARSET_USASCII	us-ascii	20127	A character set which defines 7-bit printable characters with values ranging from 20h to 7Eh. An application that uses this character set has the broadest compatibility with most mail servers (MTAs) because it does not require the server to handle 8-bit characters correctly when the message is delivered.
MIME_CHARSET_ISO8859_1	iso-8859-1	28591	A character set for most western European languages such as English, French, Spanish and German. This character set is also commonly referred to as Latin-1. This character set is similar to Windows code page 1252 (Windows-1252), however there are differences such as the Euro symbol.
MIME_CHARSET_ISO8859_2	iso-8859-2	28592	A character set for most central and eastern European languages such as Czech, Hungarian, Polish and Romanian. This character set is also commonly referred to as Latin-2. This character set is similar to Windows code page 1250, however the characters are arranged differently.
MIME_CHARSET_ISO8859_3	iso-8859-3	28593	A character set for southern European languages such as Maltese and Esperanto. This character set was also used with the Turkish language, but it was superseded by ISO 8859-9 which is the preferred character set for Turkish. This character set is not widely used in mail messages and it is recommended that you use UTF-8 instead.
MIME_CHARSET_ISO8859_4	iso-8859-4	28594	A character set for northern European languages such as Latvian, Lithuanian and Greenlandic. This character set is not widely used in mail messages and it is recommended that you use UTF-8 instead.
MIME_CHARSET_ISO8859_5	iso-8859-5	28595	A character set for Cyrillic languages such as Russian, Bulgarian and Serbian. This character set was never widely adopted and most mail messages use

			either KOI8 or UTF-8 encoding.
MIME_CHARSET_ISO8859_6	iso-8859-6	28596	A character set for Arabic languages. Note that the application is responsible for displaying text that uses this character set. In particular, any display engine needs to be able to handle the reverse writing direction and analyze the context of the message to correctly combine the glyphs.
MIME_CHARSET_ISO8859_7	iso-8859-7	28597	A character set for the Greek language. This character set is also commonly referred to as Latin/Greek. This character set is no longer widely used and has largely been replaced with UTF-8 which provides more complete coverage of the Greek alphabet.
MIME_CHARSET_ISO8859_8	iso-8859-8	28598	A character set for the Hebrew language. Note that similar to Arabic, Hebrew uses a reverse writing direction. An application which displays this character should be capable of processing bi-directional text where a single message may include both right-to-left and left-to-right languages, such as Hebrew and English. In most cases it is recommended that you use UTF-8 instead of this character set.
MIME_CHARSET_ISO8859_9	iso-8859-9	28599	A character set for the Turkish language. This character set is also commonly referred to as Latin-5. This character set is nearly identical to ISO 8859-1, except that it replaces certain Icelandic characters with Turkish characters.
MIME_CHARSET_ISO8859_10	iso-8859-10	28600	A character set for the Danish, Icelandic, Norwegian and Swedish languages. This character set is also commonly referred to as Latin-6 and is similar to ISO 8859-4.
MIME_CHARSET_ISO8859_13	iso-8859-13	28603	A character set for Baltic languages. This character set is also commonly referred to as Latin-7. This character set is similar to ISO 8859-4, except it adds certain Polish characters and does not support Nordic languages.
MIME_CHARSET_ISO8859_14	iso-8859-14	28604	A character set for Gaelic languages such as Irish, Manx and Scottish Gaelic. This character set is also commonly

			referred to as Latin-8. This character set replaced ISO 8859-12 which was never fully implemented.
MIME_CHARSET_ISO8859_15	iso-8859-15	28605	A character set for western European languages. This character set is also commonly referred to as Latin-9 and is nearly identical to ISO8859-1 except that it replaces lesser-used symbols with the Euro sign and some letters.
MIME_CHARSET_ISO2022_JP	iso-2022-jp	50220	A multi-byte character encoding for Japanese that is widely used with mail messages. This is a 7-bit encoding where all characters start with ASCII and uses escape sequences to switch to the double-byte character sets.
MIME_CHARSET_ISO2022_KR	iso-2022-kr	50225	A multi-byte character encoding for Korean which encodes both ASCII and Korean double-byte characters. This is a 7-bit encoding which uses the shift in and shift out control characters to switch to the double-byte character set.
MIME_CHARSET_ISO2022_CN	x-cp50227	50227	A multi-byte character encoding for Simplified Chinese which encodes both ASCII and Chinese double-byte characters. This is a 7-bit encoding which uses the shift in and shift out control characters to switch to the double-byte character set.
MIME_CHARSET_KOI8R	koi8-r	20866	A character set for Russian using the Cyrillic alphabet. This character set also covers the Bulgarian language. Most mail messages in the Russian language use this character set or UTF-8 instead of ISO 8859-5, which was never widely adopted.
MIME_CHARSET_KOI8U	koi8-u	21866	A character set for Ukrainian using the Cyrillic alphabet. This character set is similar to the KOI8-R character set, but replaces certain symbols with Ukrainian letters. Most mail messages in the Ukrainian language use this character set or UTF-8 instead of ISO 8859-5, which was never widely adopted.
MIME_CHARSET_GB2312	x-cp20936	20936	A multi-byte character encoding which can represent ASCII and simplified Chinese characters. It has been superseded by GB18030, however it

			remains widely used in China.
MIME_CHARSET_GB18030	gb18030	54936	A Unicode transformation format which can represent all Unicode code points and supports both simplified and traditional Chinese characters. It is backwards compatible with GB2312 and supersedes that character set.
MIME_CHARSET_BIG5	big5	950	A multi-byte character set that supports both ASCII characters and traditional Chinese characters. It is widely used in Taiwan, Hong Kong and Macau. It is no longer commonly used in China, which has developed GB18030 as a standard encoding. Microsoft's implementation of Big5 on Windows does not support all of the extensions and is missing certain code points.
MIME_CHARSET_UTF7	utf-7	65000	A Unicode transformation format that uses variable-length character encoding to represent Unicode text as a stream of ASCII characters that are safe to transport between mail servers that only support 7-bit printable characters. It is primarily used as an alternative to UTF-8 when quoted-printable or base64 encoding is not desired.
MIME_CHARSET_UTF8	utf-8	65001	A Unicode transformation format that uses multi-byte character sequences to represent Unicode text. It is backwards compatible with the ASCII character set, however because it uses 8-bit text, it is recommended that you use either quoted-printable or base64 encoding to ensure compatibility with mail servers that do not support 8-bit characters.
MIME_CHARSET_UTF16	utf-16le	N/A	A 16-bit Unicode format that represents each character as a 16-bit value in little endian byte order. This character set is not widely used in mail messages and it is recommended that you use UTF-8 instead. UTF-16 characters in big endian byte order are not supported.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

Message Store Class Library

Store a collection of email messages on the local system.

Reference

- Class Methods
- Error Codes

Library Information

Class Name	CMessageStore
File Name	CSMSGV12.DLL
Version	12.0.3024.1286
LibID	123A728A-D6CD-435F-A76D-0BA3C07DDFC1
Import Library	CSMSGV12.LIB
Dependencies	None

Overview

The Message Store class library provides an interface for managing a local message storage file that can be used to store and retrieve multiple messages. Functions are provided to open and create storage files, add, remove and extract messages from storage, and search the stored messages for specific header field values.

SocketTools also includes a class library for managing individual messages. For more information, refer to the CMailMessage class.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). If you are using Visual C++ 6.0 it is required that you have Service Pack 6 (SP6) installed. You should install all updates for your development tools and have the current Windows SDK installed. The minimum recommended version of Visual Studio is Visual Studio 2010.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are using Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. It is recommended that you install the current service pack and all critical updates available for your version of the operating system.

This product includes both 32-bit and 64-bit libraries. Native 64-bit CPU support requires the 64-bit version of Windows 7 or later versions of the Windows operating system.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Message Store Class Methods

Class	Description
CMessageStore	Constructor which initializes the current instance of the class
~CMessageStore	Destructor which releases resources allocated by the class
Method	Description
AttachHandle	Attach the specified message handle to this instance of the class
CloseFile	Close the current message storage file
CopyFile	Duplicate the contents of the current message store in a new file
DeleteMessage	Remove the specified message from the current message store
DetachHandle	Detach the handle for the current instance of this class
FindMessage	Search for a message in the current message store
GetHandle	Return the message handle used by this instance of the class
GetErrorString	Return a description for the specified error code
GetLastError	Return the last error code
GetMessage	Retrieve a message from the current message store
GetMessageCount	Return the number of messages in the current message store
IsInitialized	Determine if the class has been successfully initialized
OpenFile	Open the specified message storage file
PurgeFile	Purge all deleted messages from the current message store
ReplaceMessage	Replace the specified message in the current message store
SetLastError	Set the last error code
ShowError	Display a message box with a description of the specified error
StoreMessage	Store the specified message in the current message store

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CMessageStore::CMessageStore Method

```
CMessageStore();
```

The **CMessageStore** constructor initializes the class library and validates the license key at runtime.

Remarks

If the constructor fails to validate the runtime license, subsequent methods in this class will fail. If the product is installed with an evaluation license, then the application will only function on the development system and cannot be redistributed.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

See Also

~CMessageStore, IsInitialized

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CMessageStore::~CMessageStore

```
~CMessageStore();
```

The **CMessageStore** destructor releases resources allocated by the current instance of the **CMessageStore** object. It also uninitializes the library if there are no other concurrent uses of the class.

Remarks

When a **CMessageStore** object goes out of scope, the destructor is automatically called to allow the library to free any resources allocated on behalf of the process. All handles that were client session are destroyed.

The destructor is not called explicitly by the application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

See Also

CMessageStore

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CMessageStore::AttachHandle Method

```
VOID AttachHandle(
   HMESSAGESTORE hStorage
);
```

The **AttachHandle** method attaches the specified message store to the current instance of the class.

Parameters

hStorage

The handle to the message store that will be attached to the current instance of the class object.

Return Value

None.

Remarks

This method is used to attach a message store handle created outside of the class using the SocketTools API. Once the handle is attached to the class, the other class member functions may be used with that message store.

If a message store handle has already been created for the class, that handle will be released when the new handle is attached to the class object. If you want to prevent the previous message store from being closed, you must call the **DetachHandle** method. Failure to release the detached handle may result in a resource leak in your application.

Note that the ***hStorage*** parameter is presumed to be a valid message store handle and no checks are performed to ensure that the handle is valid. Specifying an invalid message store handle will cause subsequent method calls to fail.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

See Also

DetachHandle, GetHandle

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CMessageStore::CloseFile Method

```
BOOL CloseFile(
   BOOL bPurgeMessages
);
```

The **CloseFile** method closes the current message store.

Parameters

bPurgeMessages

An integer value which specifies if deleted messages are purged from the message store. A non-zero value specifies that all messages marked for deletion will be removed from the message store. A value of zero specifies that deleted messages will not be removed from the store.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **CloseFile** method closes the storage file that was previously opened, releasing all of the memory allocated for the message store and optionally purging all deleted messages. Note that the current message store will be closed by the class destructor when the class object is deleted or goes out of scope.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

See Also

CopyFile, OpenFile, PurgeFile

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CMessageStore::CopyFile Method

```
BOOL CopyFile(
   LPCTSTR lpszFileName
);
```

The **CopyFile** method duplicates the contents of the current message store in a new file.

Parameters

lpszFileName

A null-terminated string which specifies the name of the file that the messages will be copied to. This parameter cannot be NULL and must specify a valid file path and name.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

The **CopyFile** method is used to create a copy of the current message store in a new file. If the file does not exist, it will be created. If the file already exists, then the contents will be overwritten with the contents of the message store.

Messages that have been marked for deletion are not copied to the new message store file.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CloseFile, OpenFile, PurgeFile

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CMessageStore::DeleteMessage Method

```
BOOL DeleteMessage(
   LONG nMessageId
);
```

The **DeleteMessage** method removes the specified message from the current message store.

Parameters

nMessageId

An integer value which identifies the message that is to be removed from the message store. Message numbers begin at one and increment for each message in the store.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **DeleteMessage** method marks the specified message for deletion from the storage file. When the message store is closed or purged, the message is removed from the file. Once a message has been marked for deletion, it may no longer be referenced by the application. For example, you cannot access the contents of a message that has been deleted.

The message store must be opened with write access. This method will fail if you attempt to delete a message from a storage file that has been opened for read-only access. If the application needs to delete messages in the message store, it is recommended that the file be opened for exclusive access using the MIME_STORAGE_LOCK option.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

See Also

CloseFile, FindMessage, GetMessage, GetMessageCount, PurgeFile

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CMessageStore::DetachHandle Method

```
HMESSAGESTORE DetachHandle();
```

The **DetachHandle** method detaches the client handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the message store handle associated with the current instance of the class object. If there is no active client session, the value INVALID_MESSAGESTORE will be returned.

Remarks

This method is used to detach a message handle created by the class for use with the SocketTools API. Once the message handle is detached from the class, no other class member functions may be called. Note that the handle must be explicitly released at some later point by the process or a resource leak will occur.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

See Also

AttachHandle, GetHandle

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CMessageStore::FindMessage Method

```
LONG FindMessage(
   LONG nMessageId,
   LPCTSTR lpszHeaderName,
   LPCTSTR lpszHeaderValue,
   DWORD dwOptions
);
```

The **FindMessage** method searches for a message in the current message store.

Parameters

nMessageId

An integer value which specifies the message number that should be used when starting the search. The first message in the message store has a value of one.

lpszHeaderName

The string which specifies the name of the header field that should be searched. The header field name is not case sensitive. This parameter cannot be NULL.

lpszHeaderValue

The string which specifies the header value that should be searched for. The search options can be used to specify if the search is case-sensitive, and whether the search should return partial matches to the string. This parameter cannot be NULL.

dwOptions

A value which specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
MIME_SEARCH_DEFAULT	Perform a complete match against the specified header value. The comparison is not case-sensitive.
MIME_SEARCH_CASE_SENSITIVE	The header field value comparison will be case-sensitive. Note that this does not affect header field names. Matches for header names are always case-insensitive.
MIME_SEARCH_PARTIAL_MATCH	Perform a partial match against the specified header value. It recommended that this option be used when searching for matches to email addresses.
MIME_SEARCH_DECODE_HEADERS	Decode any encoded message headers before comparing them to the specified value. This option can increase the amount of time required to search the message store and should only be used when necessary.

Return Value

If the method succeeds, the return value is the number for the message which matches the search criteria. If the method fails, the return value is MIME_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **FindMessage** method is used to search the message store for a message which matches a specific header field value. For example, it can be used to find every message which is addressed to a specific recipient or has a subject which matches a particular string value.

Example

```
CMessageStore mailStorage;
LPCTSTR lpszHeader = _T("From");
LPCTSTR lpszAddress = _T("jsmith@example.com");
LONG nMessageId = 1;

if (! mailStorage.OpenFile(lpszFileName))
{
    // Unable to open the storage file
    return;
}

// Begin searching for messages from the specified sender
while (nMessageId != MIME_ERROR)
{
    nMessageId = mailStorage.FindMessage(nMessageId,
                                         lpszHeader,
                                         lpszAddress,
                                         MIME_SEARCH_PARTIAL_MATCH);

    if (nMessageId != MIME_ERROR)
    {
        CMailMessage mailMessage;

        // Get a copy of the message that was found
        if (mailStorage.GetMessage(nMessageId, mailMessage))
        {
            // Store the message in a file
            TCHAR szFileName[MAX_PATH];
            BOOL bExported;

            // Create a filename based on the message number
            wsprintf(szFileName, _T("msg%05ld.tmp"), nMessageId);

            // Export the message to a file
            bExported = mailMessage.Export(szFileName);
        }

        // Increase the message ID to resume the search at the next message
        nMessageId++;
    }
}

mailStorage.CloseFile();
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CMessageStore::GetErrorString Method

```
INT GetErrorString(
   DWORD dwErrorCode,
   LPTSTR lpszDescription,
   INT nMaxLength
);
```

The **GetErrorString** method is used to return a description of a specific error code. Typically this is used in conjunction with the **GetLastError** method for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

The buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length.

nMaxLength

The maximum number of characters that may be copied into the description buffer.

Return Value

If the method succeeds, the return value is the length of the description string. If the method fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the method is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetLastError, SetLastError

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CMessageStore::GetHandle Method

```
HMESSAGESTORE GetHandle();
```

The **GetHandle** method returns the message store handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the message store handle associated with the current instance of the class object. If there is no current message, the value INVALID_MESSAGESTORE will be returned.

Remarks

This method is used to obtain the message store handle created by the class for use with the SocketTools API.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

See Also

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CMessageStore::GetLastError Method

```
DWORD GetLastError();

DWORD GetLastError(
   CString& strDescription
);
```

Parameters

strDescription

A string which will contain a description of the last error code value when the method returns. If no error has been set, or the last error code has been cleared, this string will be empty.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **SetLastError** method. The Return Value section of each reference page notes the conditions under which the method sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **GetLastError** method immediately when a method's return value indicates that an error has occurred. That is because some methods call **SetLastError**(0) when they succeed, clearing the error code set by the most recently failed method.

Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_MESSAGESTORE or MIME_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

The description of the error code is the same string that is returned by the **GetErrorString** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

CMessageStore::GetMessage Method

```
BOOL GetMessage(
   LONG nMessageId,
   CMailMessage& mailMessage
);

HMESSAGE GetMessage(
   LONG nMessageId,
   DWORD dwOptions
);
```

The **GetMessage** method retrieves a message from the current message store.

Parameters

nMessageId

An integer value which specifies the message number that should be retrieved. The first message in the message store has a value of one.

mailMessage

A **CMailMessage** object which will reference the message that is retrieved from the message store.

dwOptions

A value which specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
A shared message handle returned by the function. The contents of this message will be overwritten each time this function is called.	
MIME_COPY_STORED_MESSAGE	A message handle is allocated for a copy of the message that is retrieved from the message store.

Return Value

If the first form of the method succeeds the return value is non-zero, otherwise the return value is zero. If the second form of the message succeeds it returns a message handle, otherwise it returns INVALID_MESSAGE. To get extended error information, call **GetLastError**.

Remarks

The second form of the **GetMessage** method returns a message handle for the specified message in the message store. If no options are specified, a temporary message handle is returned that is only valid until the next message is retrieved. If a multithreaded application changes the contents of the temporary message, it will change for all other threads that have obtained a message handle using this function.

If the application must have a unique copy of the message, the MIME_COPY_STORED_MESSAGE option should be specified. Instead of returning a handle to a shared message, the message is duplicated and a handle to that copy of the message is returned. If a reference to a **CMailMessage** object is passed to the first form of this method, this option is used to create a copy of the message.

Example

```
CMessageStore mailStorage;
LPCTSTR lpszHeader = _T("From");
LPCTSTR lpszAddress = _T("jsmith@example.com");
LONG nMessageId = 1;

if (! mailStorage.OpenFile(lpszFileName))
{
    // Unable to open the storage file
    return;
}

// Begin searching for messages from the specified sender
while (nMessageId != MIME_ERROR)
{
    nMessageId = mailStorage.FindMessage(nMessageId,
                                         lpszHeader,
                                         lpszAddress,
                                         MIME_SEARCH_PARTIAL_MATCH);

    if (nMessageId != MIME_ERROR)
    {
        CMailMessage mailMessage;

        // Get a copy of the message that was found
        if (mailStorage.GetMessage(nMessageId, mailMessage))
        {
            // Store the message in a file
            TCHAR szFileName[MAX_PATH];
            BOOL bExported;

            // Create a filename based on the message number
            wsprintf(szFileName, _T("msg%05ld.tmp"), nMessageId);

            // Export the message to a file
            bExported = mailMessage.Export(szFileName);
        }

        // Increase the message ID to resume the search at the next message
        nMessageId++;
    }
}

mailStorage.CloseFile();
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

See Also

CMessageStore::GetMessageCount Method

```
BOOL GetMessageCount(
   LPLONG lpnLastMessage
);
```

The **GetMessageCount** method returns the number of messages in the current message store.

Parameters

lpnLastMessage

A pointer to an integer which will contain the message number for the last message in the storage file. If this information is not required, a NULL pointer may be specified.

Return Value

If the method succeeds, the return value is the number of messages in the message store. If the method fails, the return value is MIME_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetMessageCount** method returns the number of messages in the message store. It is important to note that does not count those messages which have been marked for deletion. This means that the value returned by this function will decrease as messages are deleted.

The message number returned in the ***lpnLastMessage*** parameter will specify the total number of messages in the message store, including deleted messages.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

See Also

DeleteMessage, FindMessage, GetMessage

CMessageStore::IsInitialized Method

```
BOOL IsInitialized();
```

The **IsInitialized** method returns whether or not the class object has been successfully initialized.

Return Value

This method returns a non-zero value if the class object has been successfully initialized. A return value of zero indicates that the runtime license key could not be validated.

Remarks

When an instance of the class is created, the class constructor will attempt to initialize the component with the runtime license key that was created when SocketTools was installed. If the constructor is unable to validate the license key the initialization will fail.

If SocketTools was installed with an evaluation license, the application cannot be redistributed to another system. The class object will fail to initialize if the application is executed on another system, or if the evaluation period has expired. To redistribute your application, you must purchase a development license which will include the runtime key that is needed to redistribute your software to other systems. Refer to the Developer's Guide for more information.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

CMessageStore::OpenFile Method

```
BOOL OpenFile(
   LPCTSTR lpszFileName,
   DWORD dwOpenMode
);
```

The **OpenFile** method opens the specified message storage file.

Parameters

lpszFileName

A null-terminated string which specifies the name of the storage file.

dwOpenMode

A value which specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
MIME_STORAGE_READ	The message store will be opened for read access. The contents of the message store can be accessed, but cannot be modified by the process unless it has also been opened for writing.
MIME_STORAGE_WRITE	The message store will be opened for writing. This mode also implies read access and must be specified if the application needs to modify the contents of the message store.
MIME_STORAGE_CREATE	The message store will be created if the storage file does not exist. If the file exists, it will be truncated. This mode implies read and write access.
MIME_STORAGE_LOCK	The message store will be opened so that it may only be accessed and modified by the current process.
MIME_STORAGE_COMPRESS	The contents of the message store are compressed. This option is automatically enabled if a compressed message store is opened for reading or writing.
MIME_STORAGE_MAILBOX	The message store should use the UNIX mbox format when reading and storing messages. This option is provided for backwards compatibility and is not recommended for general use.

Return Value

If the method succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **OpenFile** method opens a message storage file which contains one or more messages. If the storage file is opened for read access, the application can search the message store and extract messages but it cannot add or delete messages. To add new messages or delete existing messages from the store, it must be opened with write access.

The message store is designed to be a simple, effective way to store multiple messages together in a single file. When the message store is opened, the contents are indexed in memory. Although there is no specific limit to the number of messages that can be stored, there must be sufficient memory available to build an index of each message and its headers. If the application must store and manage a very large number of messages, it is recommended that you use a database rather than a flat-file message store.

Message Store Format

Each message is prefixed by a control sequence of five ASCII 01 characters followed by an ASCII 10 and ASCII 13 character. The messages themselves are stored unmodified in their original text format. The length of each message is calculated based on the location of the control sequence that delimits each message, and explicit message lengths are not stored in the file. This means that it is safe to manually change the message contents, as long as the message delimiters are preserved.

If the message store is compressed, the contents of the storage file are expanded when the file is opened and then re-compressed when the storage file is closed. Using the MIME_STORAGE_COMPRESS option reduces the size of the storage file and prevents the contents of the message store from being read using a text file editor. However, enabling compression will increase the amount of memory allocated by the library and can increase the amount of time that it takes to open and close the storage file.

The class also has a backwards compatibility mode where it will recognize storage files that use the UNIX mbox format. While this format is supported for accessing existing files, it is not recommended that you use it when creating new message stores or adding messages to an existing store. There are a number of different variants on the mbox format that have been used by different Mail Transfer Agents (MTAs) on the UNIX platform. For example, the mboxrd variant looks identical to the mboxcl2 variant, and they are programmatically indistinguishable from one another, but they are not compatible. For this reason, the use of the mbox format is strongly discouraged.

Example

```
CMailMessage mailMessage;

// Compose a new message
mailMessage.Compose(lpszSender,
                            lpszRecipient,
                            NULL,
                            lpszSubject,
                            lpszMessage,
                            NULL,
                            MIME_CHARSET_DEFAULT,
                            MIME_ENCODING_DEFAULT);

CMessageStore mailStorage;

// Open the message storage file
if (mailStorage.OpenFile(lpszFileName, MIME_STORAGE_WRITE))
{
    // Store a copy of the message in the message store
    nMessageId = mailStorage.StoreMessage(mailMessage);

    if (nMessageId == MIME_ERROR)
    {
        // We were unable to store the message
    }
```

```
    // Close the message store
    mailStorage.CloseFile();
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CloseFile, FindMessage, GetMessage, GetMessageCount, PurgeFile

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CMessageStore::PurgeFile Method

```
BOOL PurgeFile();
```

The **PurgeFile** method purges all deleted messages from the specified message store.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **PurgeFile** method purges all deleted messages from the message store. If the storage file has been opened in read-only mode or there are no messages marked for deletion, this method will take no action.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

See Also

CMessageStore::ReplaceMessage Method

```
BOOL ReplaceMessage(
   LONG nMessageId,
   CMailMessage& mailMessage
);

BOOL ReplaceMessage(
   LONG nMessageId,
   HMESSAGE hMessage
);
```

The **MimeReplaceStoredMessage** function replaces the contents of the specified message in a message store.

Parameters

nMessageId

An integer value which specifies the message number that should be replaced.

mailMessage

A **CMailMessage** object which references the message that will be stored.

hMessage

Handle to the message that will be stored.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

The **ReplaceMessage** method replaces the specified message with a new message. The message number may be a message that has been previously marked for deletion. It is important to note that the change will not be reflected in the physical storage file until it has been closed. If the application needs to replace messages in the message store, it is recommended that the file be opened for exclusive access using the MIME_STORAGE_LOCK option.

Example

```
CMailMessage mailMessage;

// Compose a new message
mailMessage.Compose(lpszSender,
                            lpszRecipient,
                            NULL,
                            lpszSubject,
                            lpszMessage);

CMessageStore mailStorage;

if (mailStorage.OpenFile(lpszFileName, MIME_STORAGE_WRITE))
{
    LONG nLastMessage = 0;

    // Get the last message number in the message store
    mailStorage.GetMessageCount(&nLastMessage);
```

```
    if (nLastMessage > 0)
    {
        // Replace the last message in the message store
        if (!mailStorage.ReplaceMessage(nLastMessage, mailMessage))
        {
            // We were unable to replace the message
        }
    }

    // Close the message store
    mailStorage.CloseFile();
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

See Also

FindMessage, GetMessage, DeleteMessage, StoreMessage

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CMessageStore::SetLastError Method

```
VOID SetLastError(
   DWORD dwErrorCode
);
```

The **SetLastError** method sets the last error code for the current thread. This method is typically used to clear the last error by specifying a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_MESSAGESTORE or MIME_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

Applications can retrieve the value saved by this method by using the **GetLastError** method. The use of **GetLastError** is optional; an application can call the method to determine the specific reason for a method failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

See Also

GetErrorString, GetLastError, ShowError

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CMessageStore::ShowError Method

```
INT ShowError(
   LPCTSTR lpszAppTitle,
   UINT uType,
   DWORD dwErrorCode
);
```

The **ShowError** method displays a message box which describes the specified error.

Parameters

lpszAppTitle

A null-terminated string which specifies the title of the message box that is displayed. If this argument is NULL or omitted, then the default title of "Error" will be displayed.

uType

An unsigned integer which specifies the type of message box that will be displayed. This is the same value that is used by the **MessageBox** method in the Windows API. If a value of zero is specified, then a message box with a single OK button will be displayed. Refer to that method for a complete list of options.

dwErrorCode

Specifies the error code that will be used when displaying the message box. If this argument is zero, then the last error that occurred in the current thread will be displayed.

Return Value

If the method is successful, the return value will be the return value from the **MessageBox** function. If the method fails, it will return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetErrorString, GetLastError, SetLastError

CMessageStore::StoreMessage Method

```
LONG StoreMessage(
   CMailMessage& mailMessage
);
```

```
LONG StoreMessage(
   HMESSAGE hMessage
);
```

The **StoreMessage** method stores the specified message in the current message store.

Parameters

hStorage

Handle to the message store.

mailMessage

A **CMailMessage** object which references the message that will be stored.

hMessage

Handle to the message that will be stored.

Return Value

If the method succeeds, the return value is the message number for the message that was just stored. If the method fails, the return value is MIME_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **StoreMessage** method will always append the specified message to the storage file. If you want to replace a message in the message store, you should use the **DeleteMessage** method to mark the original message for deletion and then use **StoreMessage** to write the updated message to the message store.

Example

```
CMailMessage mailMessage;

// Compose a new message
mailMessage.Compose(lpszSender,
                            lpszRecipient,
                            NULL,
                            lpszSubject,
                            lpszMessage,
                            NULL,
                            MIME_CHARSET_DEFAULT,
                            MIME_ENCODING_DEFAULT);

CMessageStore mailStorage;

// Open the message storage file
if (mailStorage.OpenFile(lpszFileName, MIME_STORAGE_WRITE))
{
    // Store a copy of the message in the message store
    nMessageId = mailStorage.StoreMessage(mailMessage);

    if (nMessageId == MIME_ERROR)
```

```
    {
        // We were unable to store the message
    }

    // Close the message store
    mailStorage.CloseFile();
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

Network Time Protocol Class Library

Query a network time server for the current date and time.

Reference

- Class Methods
- Data Structures
- Error Codes

Library Information

Class Name	CNetworkTime
File Name	CSTIMV12.DLL
Version	12.0.3024.1286
LibID	79C32362-35E2-4115-9F08-043C7F982BB8
Import Library	CSTIMV12.LIB
Dependencies	None
Standards	RFC 868, RFC 5905

Overview

The Network Time Protocol class provides an interface for obtaining the current date and time from a server. The time is returned in Coordinated Universal Time (UCT) and can be adjusted for the local host's timezone. The time value is returned as the number of seconds which have elapsed since midnight, January 1, 1900. The class supports the Network Time Protocol (NTP) as specified in RFC 5905 and the TIME protocol described in RFC 868.

It is recommended you update your applications to call the methods which use 64-bit integer time values and use the NTP v4 protocol, which is supported in the current version of this API. To use NTP v4, provide the name of a valid NTP server and specify port 123. Although the API continues to support the TIME protocol on port 37, its use has been deprecated and applications should be updated to use NTP which is considered a more reliable method for obtaining the current time over the Internet.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). You should install all updates for your development tools and have the current Windows SDK installed. The minimum supported version of Visual Studio is Visual Studio 2010 with Service Pack 1 (SP1) installed. The SocketTools header files are designed to be compatible with all modern C/C++ compilers and we also provide function definitions for several additional languages such as Object Pascal and Visual Basic.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are deploying applications to Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. If you are deploying applications to Windows 8, you must have the 8.1 update installed. If you are targeting the Windows on ARM platform, the minimum required version is Windows 10 build 1709.

SocketTools includes support for both 64-bit and 32-bit Windows platforms. All current versions of Windows are 64-bit, and we include 32-bit x86 libraries to maintain compatibility with legacy development tools. SocketTools also provides native ARM64 libraries for systems running Windows on ARM. Note that 32-bit applications on ARM use x86 emulation, and Microsoft no longer supports native 32-bit ARM (ARM32) applications. Embarcadero's C++Builder and Delphi compilers (as of version 12.3) do not support building native ARM64 applications for Windows. For developing applications targeting the Windows on ARM platform, we recommend using Visual Studio 2019 or later.

The import libraries included with SocketTools are provided in several different formats. The most commonly used format is COFF, which is available for x64, x86 and native ARM64 platforms. For compatibility with older Borland (Embarcadero) compilers, we also provide OMF libraries for x86 platforms and ELF libraries for x64 platforms. If you are using Visual Studio, you will want to use the standard COFF import libraries. Note that some languages may not require import libraries and will link to the exported functions in the DLL based on the function declaration itself.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Network Time Protocol Class Methods

Class	Description
CNetworkTime	Constructor which initializes the current instance of the class
~CNetworkTime	Destructor which releases resources allocated by the class
Method	Description
ConvertTime	Convert between network and system time values
DisableTrace	Disable logging of network function calls
EnableTrace	Enable logging of network function calls to a file
FormatTime	Return the specified network time as a string formatted for the current locale.
GetErrorString	Return a description for the specified error code
GetLastError	Return the last error code
GetTime	Return the current network time from the server
IsInitialized	Determine if the class has been successfully initialized
SetLastError	Set the last error code
SetTime	Set the local system time with the network time

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNetworkTime::~CNetworkTime

```
~CNetworkTime();
```

The **CNetworkTime** destructor releases resources allocated by the current instance of the **CNetworkTime** object. It also uninitializes the library if there are no other concurrent uses of the class.

Remarks

When a **CNetworkTime** object goes out of scope, the destructor is automatically called to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all handles that were created for the client session are destroyed.

The destructor is not called explicitly by the application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstimv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CNetworkTime

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNetworkTime::CNetworkTime Method

```
CNetworkTime();
```

The **CNetworkTime** constructor initializes the class library and validates the license key at runtime.

Remarks

If the constructor fails to validate the runtime license, subsequent methods in this class will fail. If the product is installed with an evaluation license, then the application will only function on the development system and cannot be redistributed.

The constructor calls the **TimeInitialize** function to initialize the library, which dynamically loads other system libraries and allocates thread local storage. If you are using this class within another DLL, it is important that you do not create or destroy an instance of the class from within the **DllMain** function because it can result in deadlocks or access violation errors. You should not declare static or global instances of this class within another DLL if it is linked with the C runtime library (CRT) because it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstimv12.lib
Unicode: Implemented as Unicode and ANSI versions

CNetworkTime::ConvertTime Method

```
BOOL ConvertTime(
   ULONGLONG ulNetworkTime,
   LPSYSTEMTIME lpSystemTime,
   BOOL bLocalTime
);

BOOL ConvertTime(
   ULONGLONG ulNetworkTime,
   TIME_T* lpUnixTime
);

BOOL ConvertTime(
   ULONGLONG ulNetworkTime,
   CTime& localTime
);

BOOL ConvertTime(
   LPSYSTEMTIME lpSystemTime,
   ULONGLONG* lpNetworkTime
);
```

The **ConvertTime** method converts between a 32-bit network time value and a SYSTEMTIME structure.

Parameters

ulNetworkTime

The network time to be converted.

lpUnixTime

A pointer to a long integer which will contain the time in UNIX format. The value is the number of seconds since 1 January 1970 UTC and is commonly used with the standard C library time functions.

localTime

A **CTime** object which will contain the local time when the method returns.

lpSystemTime

A pointer to a SYSTEMTIME structure which will be modified for the specified network time.

bLocalTime

A boolean flag that is used to specify if the network time should be adjusted for the local timezone.

Return Value

If the network time can be converted, the method returns a non-zero value. If the network time cannot be converted, or the pointer to the SYSTEMTIME structure is invalid, the method will return zero.

Remarks

The network time value is a 64-bit number, represented as the number of seconds since midnight, 1 January 1900 UTC.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools12.h
Import Library: cstimv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

FormatTime, GetTime, SetTime

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNetworkTime::DisableTrace Method

```
BOOL DisableTrace();
```

The **DisableTrace** method disables the logging of network function calls.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, a value of zero is returned.

Remarks

This method will disable output to the log file for the current thread or process, depending on the flags used when logging was enabled. If this method is not called, the resources that were allocated for the logging session will be released when the process ends.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstimv12.lib

See Also

EnableTrace

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNetworkTime::EnableTrace Method

```
BOOL EnableTrace(
   LPCTSTR lpszTraceFile,
   DWORD dwTraceFlags
);
```

The **EnableTrace** method enables the logging of network function calls to a file.

Parameters

lpszTraceFile

A null-terminated string which specifies the name of the logfile which will be appended to or created. It is recommended that this file always specify an absolute path to avoid any ambiguity. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
TRACE_INFO	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
TRACE_ERROR	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
TRACE_HEXDUMP	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
TRACE_TRUNCATE	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for

	multithreaded applications that are using worker threads.

Return Value

If the method succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the log file cannot be created.

Remarks

Logging is enabled and disabled at the thread or process level, depending on the flags passed to this method, and is not associated with a specific class instance. When logging is enabled, the information is appended to the specified file. If the file does not exist, it will be created. To limit the size of the file, enable and disable logging only around those sections of code that you wish to debug. If you do not provide a full path to the file, it will be relative to the current working directory for the process. This can produce unexpected results in multithreaded applications because the current directory is global to the entire process and can be changed by any thread at any time.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

The TRACE_HEXDUMP option can generate very large files because it includes all of the data exchanged between your application and the remote host. The TRACE_TRUNCATE option is only evaluated when logging is first enabled for a thread or process. If logging is already active, specifying this option will have no effect.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "**0x**". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxxx:xxxx::xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, a connection is being made to a system with the IPv4 address 192.0.0.1 on port 1234.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstimv12.lib
Unicode: Implemented as Unicode and ANSI versions

CNetworkTime::FormatTime Method

```
INT FormatTime(
   ULONGLONG ulNetworkTime,
   LPTSTR lpszDateTime,
   INT nMaxLength,
   BOOL bLocalTime
);

INT FormatTime(
   ULONGLONG ulNetworkTime,
   CString& strDateTime,
   BOOL bLocalTime
);
```

The **FormatTime** method converts the network time to a string value which contains the date and time formatted for the current locale.

Parameters

ulNetworkTime

An unsigned integer value which specifies the network time. This value should specify the number of seconds since midnight, January 1, 1900 UTC.

lpszDateTime

A null-terminated string buffer which will contain the formatted date and time. This buffer must be large enough to store both date and time values, including the terminating null character. The date is formatted using the current system locale's short date format. The time is formatted to use a 24-hour clock and includes the seconds value. An alternate version of this method accepts a reference to a **CString** object which will contain the date and time when the method returns.

nMaxLength

The maximum number of characters which can be copied into the string buffer, including the terminating null character. If the buffer is not large enough to contain the entire date and time string, the function will fail and return a value of zero.

bLocalTime

An integer boolean value which specifies if the network time should be adjusted for the local timezone. If this parameter is zero, the date and time are formatted using Coordinated Universal Time (UTC). If this parameter is non-zero, the network time value will be adjusted for the current timezone and will return a localized time value. The current timezone is determined by the configuration of the local system.

Return Value

If successful, the method returns the number of characters copied into the string buffer, not including the terminating null character. If the method fails, it returns a value of zero. Call the **GetLastError** method for more information about the cause of the failure.

Remarks

The **FormatTime** method is a convenient way to convert a numeric network time value to a string value which can be displayed to the user. The actual format of the string is determined by the local system configuration and locale. For example, in North America the date string will be returned using a month/day/year format, while European locales may return the date in a day/month/year format.

Example

```
// Request the time from a server and write it to standard output
CNetworkTime timeClient;
ULONGLONG ulNetworkTime = timeClient.GetTime(_T("time.nist.gov"),
TIME_PORT_DEFAULT, TIME_TIMEOUT);

if (ulNetworkTime != 0)
{
    CString strDateTime;
    INT nLength = timeClient.FormatTime(ulNetworkTime, strDateTime, TRUE);

    if (nLength > 0)
        _tprintf(_T("The local date and time is %s\n"), (LPCTSTR)strDateTime);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstimv12.lib

CNetworkTime::GetErrorString Method

```
INT GetErrorString(
   DWORD dwErrorCode,
   LPTSTR lpszDescription,
   INT nMaxLength
);

INT GetErrorString(
   DWORD dwErrorCode,
   CString& strDescription
);
```

The **GetErrorString** method is used to return a description of a specific error code. Typically this is used in conjunction with the **GetLastError** method for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

The buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length. An alternate form of the method accepts a **CString** variable which will contain the error description.

nMaxLength

The maximum number of characters that may be copied into the description buffer.

Return Value

If the method succeeds, the return value is the length of the description string. If the method fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the method is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstimv12.lib
Unicode: Implemented as Unicode and ANSI versions

CNetworkTime::GetLastError Method

```
DWORD GetLastError();

DWORD GetLastError(
   CString& strDescription
);
```

Parameters

strDescription

A string which will contain a description of the last error code value when the method returns. If no error has been set, or the last error code has been cleared, this string will be empty.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **SetLastError** method. The Return Value section of each reference page notes the conditions under which the method sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **GetLastError** method immediately when a method's return value indicates that an error has occurred. That is because some methods call **SetLastError**(0) when they succeed, clearing the error code set by the most recently failed method.

Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or TIME_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

The description of the error code is the same string that is returned by the **GetErrorString** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstimv12.lib

CNetworkTime::GetTime Method

```
BOOL GetTime(
   LPCTSTR lpszHostName,
   UINT nHostPort,
   ULONGLONG* lpNetworkTime
   UINT nTimeout
);

BOOL GetTime(
   LPCTSTR lpszHostName,
   UINT nHostPort,
   LPSYSTEMTIME lpSystemTime
   UINT nTimeout
);

BOOL GetTime(
   LPCTSTR lpszHostName,
   UINT nHostPort,
   CTime& localTime
   UINT nTimeout
);
```

The **GetTime** method returns the network time from the specified host.

Parameters

lpszHostName

The name of the server. The host must be running a time server that complies with the specifications outlined in RFC 868.

nHostPort

The port the time server is running on. A value of zero indicates that the default port number for the service should be used. By default, port 123 is used to connect to the time server.

lpNetworkTime

A pointer to an unsigned 64-bit integer which will contain the current network time when the method returns. Note that this value is not the same as UNIX time and cannot be used with the standard C time functions.

lpSystemTime

A pointer to a SYSTEMTIME structure that will contain the system time when the method returns. This structure can be used with many of the standard Windows API time-related functions.

localTime

A **CTime** object that will contain the local time when the method returns.

nTimeout

The number of seconds that the method will wait for a response from the server.

Return Value

If the method succeeds, it returns the number of seconds since midnight, 1 January 1900 UTC. If the method was unable to obtain the time from the specified host, it returns zero.

Remarks

The **GetTime** method will cause the calling thread to block until the time is returned by the server, or

the operation times out. If you do not want the current thread to block, you can create a worker thread and call this function from within that thread. The blocking network call in the worker thread will not interefere with any other threads in your application.

In most cases, it is preferable to use the NTP pool servers which distribute requests over a number of different servers:

- **pool.ntp.org** is a global load-balanced pool of time servers
- **us.pool.ntp.org** servers are located in the United States
- **eu.pool.ntp.org** servers are located in Europe
- **asia.pool.ntp.org** servers are located in Asia

There are also load balanced pools of time servers available in specific countries prefixed by their country code. For example, the **de.pool.ntp.org** servers are located in Germany and the **uk.pool.ntp.org** servers are located in the United Kingdom. Regardless of their location, the time values they return are always in Coordinated Universal Time (UTC) and are not localized based on the physical location of the server.

In the United States, the National Institute of Standards and Technology (NIST) hosts a number of public servers which can be used to obtain the current time. The following table lists the current host names and addresses:

Server Name	IP Address	Location
time-a-g.nist.gov	129.6.15.28	Gaithersburg, Maryland
time-b-g.nist.gov	129.6.15.29	Gaithersburg, Maryland
time-nw.nist.gov	131.107.13.100	Redmond, Washington
time-a-b.nist.gov	132.163.96.1	Boulder, Colorado
time-b-b.nist.gov	132.163.96.2	Boulder, Colorado
time-c-b.nist.gov	132.163.96.3	Boulder, Colorado

Time servers are also commonly maintained by government agencies and universities. If you are unable to obtain the time from a server, contact the system administrator to determine if they support the standard time service available on port 123.

If you are requesting the time from a public server, you should ensure that your application does not send too many requests over a short period of time. In most cases, you should not query a time server more than once per minute. Most public time servers will block the IP addresse of a client which sends too many requests.

It is important to note that the network time value is not the same as the UNIX time value used with the standard C runtime library. The **time()** function returns the number of seconds since January 1, 1970 which is commonly referred to as the UNIX epoch. NTP servers return the time as the number of seconds since January 1, 1900.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstimv12.lib
Unicode: Implemented as Unicode and ANSI versions

CNetworkTime::IsInitialized Method

```
BOOL IsInitialized();
```

The **IsInitialized** method returns whether or not the class object has been successfully initialized.

Parameters

None.

Return Value

This method returns a non-zero value if the class object has been successfully initialized. A return value of zero indicates that the runtime license key could not be validated or the networking library could not be loaded by the current process.

Remarks

When an instance of the class is created, the class constructor will attempt to initialize the component with the runtime license key that was created when SocketTools was installed. If the constructor is unable to validate the license key or load the networking libraries, this initialization will fail.

If SocketTools was installed with an evaluation license, the application cannot be redistributed to another system. The class object will fail to initialize if the application is executed on another system, or if the evaluation period has expired. To redistribute your application, you must purchase a development license which will include the runtime key that is needed to redistribute your software to other systems. Refer to the Developer's Guide for more information.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstimv12.lib

See Also

CNetworkTime

CNetworkTime::SetLastError Method

```
VOID SetLastError(
   DWORD dwErrorCode
);
```

The **SetLastError** method sets the error code for the current thread. This method is typically used to clear the last error by passing a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or TIME_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

Applications can retrieve the value saved by this method by using the **GetLastError** method. The use of **GetLastError** is optional; an application can call the method to determine the specific reason for a method failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstimv12.lib

See Also

CNetworkTime::SetTime Method

```
BOOL SetTime(
   ULONGLONG ulNetworkTime
);

BOOL SetTime(
   LPSYSTEMTIME lpSystemTime
);
```

The **SetTime** method sets the local system clock to the specified date and time.

Parameters

ulNetworkTime

The date and time the system clock should be set to, represented as the number of seconds since midnight, 1 January 1900.

lpSystemTime

A pointer to a SYSTEMTIME structure that specifies the date and time that the local clock should be set to.

Return Value

If the method is able to update the local time, it returns a non-zero value. If the specified time is invalid, or the user does not have the access rights to change the system clock, the method returns zero.

Remarks

The **SetTime** method updates the local system clock to the specified date and time. The user must have the appropriate privileges to change the system clock, otherwise an error will be returned. This typically requires the application to execute with elevated privileges. Because Windows systems are usually configured to automatically synchronize the system clock with a time server using the Windows Time service (W32Time), most applications should not use this function.

It is important to note that the network time value is not the same as the UNIX time value used with the standard C runtime library. The **time()** function returns the number of seconds since January 1, 1970 which is commonly referred to as the UNIX epoch.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstimv12.lib

CNetworkTime::ShowError Method

```
INT ShowError(
   LPCTSTR lpszAppTitle,
   UINT uType,
   DWORD dwErrorCode
);
```

The **ShowError** method displays a message box which describes the specified error.

Parameters

lpszAppTitle

A null-terminated string which specifies the title of the message box that is displayed. If this argument is NULL or omitted, then the default title of "Error" will be displayed.

uType

An unsigned integer which specifies the type of message box that will be displayed. This is the same value that is used by the **MessageBox** method in the Windows API. If a value of zero is specified, then a message box with a single OK button will be displayed. Refer to that method for a complete list of options.

dwErrorCode

Specifies the error code that will be used when displaying the message box. If this argument is zero, then the last error that occurred in the current thread will be displayed.

Return Value

If the method is successful, the return value will be the return value from the **MessageBox** function. If the method fails, it will return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstimv12.lib
Unicode: Implemented as Unicode and ANSI versions

SYSTEMTIME

The **SYSTEMTIME** structure represents a date and time using individual members for the month, day, year, weekday, hour, minute, second, and millisecond.

```
typedef struct _SYSTEMTIME
{
    WORD wYear;
    WORD wMonth;
    WORD wDayOfWeek;
    WORD wDay;
    WORD wHour;
    WORD wMinute;
    WORD wSecond;
    WORD wMilliseconds;
} SYSTEMTIME, *LPSYSTEMTIME;
```

Members

wYear

Specifies the current year. The year value must be greater than 1601.

wMonth

Specifies the current month. January is 1, February is 2 and so on.

wDayOfWeek

Specifies the current day of the week. Sunday is 0, Monday is 1 and so on.

wDay

Specifies the current day of the month

wHour

Specifies the current hour.

wMinute

Specifies the current minute

wSecond

Specifies the current second.

wMilliseconds

Specifies the current millisecond.

Requirements

Network News Transfer Protocol Class Library

Download and submit articles to a news server.

Reference

- Class Methods
- Data Structures
- Error Codes

Library Information

Class Name	CNntpClient
File Name	CSNWSV12.DLL
Version	12.0.3024.1286
LibID	C11CFCC7-8D02-4CB5-B3D2-003BD1D65C40
Import Library	CSNWSV12.LIB
Dependencies	None
Standards	RFC 977, RFC 2980

Overview

The Network News Transfer Protocol (NNTP) is used with servers that provide news services. This is similar in functionality to bulletin boards or message boards, where topics are organized hierarchically into groups, called newsgroups. Users can browse and search for messages, called news articles, which have been posted by other users. On many servers, they can also post their own articles which can be read by others. The largest collection of public newsgroups available is called USENET, a world-wide distributed discussion system. In addition, there are a large number of smaller news servers. For example, Catalyst Development operates a news server which methods as a forum for technical questions and announcements.

The SocketTools library provides a comprehensive interface for accessing newsgroups, retrieving articles and posting new articles. In combination with the Mail Message library to process the news articles, SocketTools can be used to integrate newsgroup access with an existing email application, or you can implement your own full-featured newsgroup client.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). You should install all updates for your development tools and have the current Windows SDK installed. The minimum supported version of Visual Studio is Visual Studio 2010 with Service Pack 1 (SP1) installed. The SocketTools header files are designed to be compatible with all modern C/C++ compilers and we also provide function definitions for several additional languages such as Object Pascal and Visual Basic.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are deploying applications to Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. If you are deploying applications to Windows 8, you must have the 8.1 update installed. If you are targeting the Windows on ARM platform, the minimum required version is Windows 10 build 1709.

SocketTools includes support for both 64-bit and 32-bit Windows platforms. All current versions of Windows are 64-bit, and we include 32-bit x86 libraries to maintain compatibility with legacy development tools. SocketTools also provides native ARM64 libraries for systems running Windows on ARM. Note that 32-bit applications on ARM use x86 emulation, and Microsoft no longer supports native 32-bit ARM (ARM32) applications. Embarcadero's C++Builder and Delphi compilers (as of version 12.3) do not support building native ARM64 applications for Windows. For developing applications targeting the Windows on ARM platform, we recommend using Visual Studio 2019 or later.

The import libraries included with SocketTools are provided in several different formats. The most commonly used format is COFF, which is available for x64, x86 and native ARM64 platforms. For compatibility with older Borland (Embarcadero) compilers, we also provide OMF libraries for x86 platforms and ELF libraries for x64 platforms. If you are using Visual Studio, you will want to use the standard COFF import libraries. Note that some languages may not require import libraries and will link to the exported functions in the DLL based on the function declaration itself.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Network News Transfer Protocol Class Methods

Class	Description
CNntpClient	Constructor which initializes the current instance of the class
~CNntpClient	Destructor which releases resources allocated by the class
Method	Description
AttachHandle	Attach the specified client handle to this instance of the class
AttachThread	Attach the specified client handle to another thread
Authenticate	Authenticate the specified user on the news server
Cancel	Cancel the current blocking operation
CloseArticle	Close the article being posted to the current newsgroup
Command	Send a command to the server
Connect	Connect to the specified server
CreateArticle	Create a new article in the current newsgroup
CreateSecurityCredentials	Create a new security credentials structure
DeleteSecurityCredentials	Delete a previously created security credentials structure
DetachHandle	Detach the handle for the current instance of this class
DisableEvents	Disable asynchronous event notification
DisableTrace	Disable logging of network function calls
Disconnect	Disconnect from the current server
EnableEvents	Enable asynchronous event notification
EnableTrace	Enable logging of network function calls to a file
FreezeEvents	Suspend asynchronous event processing
GetArticle	Copy the specified article to a local buffer
GetArticleHeaders	Return the contents of the specified article header
GetArticleMessageId	Return the message identifier for the specified article
GetArticleRange	Return the first and last article number for the current group
GetCurrentArticle	Return the current article number for the selected group
GetCurrentDate	Return the current date and time
GetErrorString	Return a description for the specified error code
GetFirstArticle	Return the first available article in the currently selected newsgroup
GetFirstGroup	Return the first available newsgroup from the server
GetHandle	Return the client handle used by this instance of the class
GetGroupName	Return the name of the currently selected newsgroup

GetGroupTitle	Return a description of the currently selected newsgroup
GetLastError	Return the last error code
GetMessageIdArticle	Return the article number for the specified message identifier
GetNextArticle	Return the next available article from the currently selected newsgroup
GetNextGroup	Return the next available newsgroup from the server
GetResultCode	Return the result code from the previous command
GetResultString	Return the result string from the previous command
GetSecurityInformation	Return security information about the current client connection
GetStatus	Return the current client status
GetTimeout	Return the number of seconds until an operation times out
GetTransferStatus	Return data transfer statistics
IsBlocking	Determine if the client is blocked, waiting for information
IsConnected	Determine if the client is connected to the server
IsInitialized	Determine if the class has been successfully initialized
IsReadable	Determine if data can be read from the server
IsWritable	Determine if data can be written to the server
ListArticles	Return a list of articles in the currently selected newsgroup
ListGroups	Return a list of newsgroups maintained by the server
NntpEventProc	Callback method that processes events generated by the client
OpenArticle	Open the specified article in the currently selected newsgroup
OpenNextArticle	Open the next available article
OpenPreviousArticle	Open the previous article
PostArticle	Post a new article to the news server
Read	Read data returned by the news server
RegisterEvent	Register an event callback function
Reset	Reset the client
SelectGroup	Select the specified newsgroup to retrieve articles from
SetLastError	Set the last error code
SetTimeout	Set the number of seconds until an operation times out
ShowError	Display a message box with a description of the specified error
StoreArticle	Store the specified article to a file on the local system
Write	Write data to the news server

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNntpClient::CNntpClient Method

```
CNntpClient();
```

The **CNntpClient** constructor initializes the class library and validates the license key at runtime.

Remarks

If the constructor fails to validate the runtime license, subsequent methods in this class will fail. If the product is installed with an evaluation license, then the application will only function on the development system and cannot be redistributed.

The constructor calls the **NntpInitialize** function to initialize the library, which dynamically loads other system libraries and allocates thread local storage. If you are using this class within another DLL, it is important that you do not create or destroy an instance of the class from within the **DllMain** function because it can result in deadlocks or access violation errors. You should not declare static or global instances of this class within another DLL if it is linked with the C runtime library (CRT) because it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

~CNntpClient, IsInitialized

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNntpClient::~CNntpClient

```
~CNntpClient();
```

The **CNntpClient** destructor releases resources allocated by the current instance of the **CNntpClient** object. It also uninitializes the library if there are no other concurrent uses of the class.

Remarks

When a **CNntpClient** object goes out of scope, the destructor is automatically called to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all handles that were created for the client session are destroyed.

The destructor is not called explicitly by the application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CNntpClient

CNntpClient::AttachHandle Method

```
VOID AttachHandle(
   HCLIENT hClient
);
```

The **AttachHandle** method attaches the specified client handle to the current instance of the class.

Parameters

hClient

The handle to the client session that will be attached to the current instance of the class object.

Return Value

None.

Remarks

This method is used to attach a client handle created outside of the class using the SocketTools API. Once the client handle is attached to the class, the other class member functions may be used with that client session.

If a client handle has already been created for the class, that handle will be released when the new handle is attached to the class object. If you want to prevent the previous client session from being terminated, you must call the **DetachHandle** method. Failure to release the detached handle may result in a resource leak in your application.

Note that the ***hClient*** parameter is presumed to be a valid client handle and no checks are performed to ensure that the handle is valid. Specifying an invalid client handle will cause subsequent method calls to fail.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

See Also

AttachThread, DetachHandle, GetHandle

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNntpClient::AttachThread Method

```
DWORD AttachThread(
   DWORD dwThreadId
);
```

The **AttachThread** method attaches the specified client handle to another thread.

Parameters

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the method succeeds, the return value is the thread ID of the previous owner. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

When a client handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in a client application to create the client handle, and then pass that handle to another worker thread. The **AttachThread** method can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the method, the original owner of the handle can be restored before the worker thread terminates.

This method should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **AttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **Cancel** method and then release the handle after the blocking method exits and control is returned to the current thread.

Note that the ***dwThreadId*** parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the client handle used by the class until the destructor is called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

See Also

AttachHandle, Cancel, Connect, DetachHandle, Disconnect, GetHandle

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNntpClient::Authenticate Method

```
INT Authenticate(
   LPCTSTR lpszUserName,
   LPCTSTR lpszPassword
);
```

The **Authenticate** method is used to authenticate access to the news server. Not all news servers require authentication by the client.

Parameters

lpszUserName

Pointer to a string which specifies the user name required for authentication on the news server.

lpszPassword

Pointer to a string which specifies the password required for authentication on the news server.

Return Value

If the method succeeds, the return value is the server result code. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

This method should only be called if the server requires authentication. Two authentication methods, "original" and "simple" authentication, are recognized by the library.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

Connect, ListArticles, ListGroups

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNntpClient::Cancel Method

```
INT Cancel();
```

The **Cancel** method cancels any outstanding blocking operation in the client, causing the blocking method to fail. The application may then retry the operation or terminate the client session.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

When the **Cancel** method is called, the blocking method will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

See Also

IsBlocking

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNntpClient::CloseArticle Method

```
INT CloseArticle();
```

The **CloseArticle** method closes the current article that has been opened or created.

Parameters

None.

Return Value

If the method succeeds, the return value is the server result code. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

If an article is being created, this method actually submits the article to the server. Note that the client application is responsible for generating the message headers as well as the body of the message. News articles conform to the same general characteristics of an email message.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

CNntpClient::Command Method

```
INT Command(
   LPCTSTR lpszCommand,
   LPCTSTR lpszParameter,
   BOOL bMultiLine
);
```

The **Command** method sends a command to the server, and returns the result code back to the caller. This method is typically used for site-specific commands not directly supported by the class.

Parameters

lpszCommand

The command which will be executed by the server.

lpszParameter

An optional command parameter. If the command requires more than one parameter, then they should be combined into a single string, with a space separating each parameter. If the command does not accept any parameters, this value may be NULL.

bMultiLine

An optional boolean argument used to specify if multiple lines of data will be returned by the server as the result of the command. Unlike a single line response, which consists of a result code and result string, a multi-line response consists of one or more lines of text, terminated by a special end-of-data marker. If this argument is omitted, ***bMultiLine*** is FALSE.

Return Value

If the method succeeds, the return value is the result code returned by the server. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

A list of valid commands can be found in the technical specification for the protocol. Many servers will list supported commands when the HELP command is used.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

CNntpClient::Connect Method

```
BOOL Connect(
   LPCTSTR lpszRemoteHost,
   UINT nRemotePort,
   UINT nTimeout,
   DWORD dwOptions
);
```

The **Connect** method establishes a connection with the specified server.

Parameters

lpszRemoteHost

The name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on; a value of zero specifies that the default port number should be used. For standard connections, the default port number is NN. For secure connections, the default port number is NN.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
NNTP_OPTION_NONE	No connection options specified. A standard connection to the server will be established using the specified host name and port number.
NNTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
NNTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
NNTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using the TLS protocol.
NNTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will

	allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
NNTP_OPTION_FREETHREAD	This option specifies that this instance of the class may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the class instance is synchronized across multiple threads.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method will block the current thread until a connection has been established or the timeout period has elapsed. To prevent it from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling the **Connect** method in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each connection.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the class instance is initially attached to the thread that created it. From that point on, until the handle is released, only the owner may call functions using that instance of the class. The ownership of the class instance may be transferred from one thread to another using the **AttachThread** method.

Specifying the NNTP_OPTION_FREETHREAD option enables any thread to call any method in that instance of the class, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the class instance is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same instance.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

CNntpClient::CreateArticle Method

```
INT CreateArticle();
```

The **CreateArticle** method creates a new article in the current newsgroup.

Parameters

None.

Return Value

If the method succeeds, the return value is the server result code. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

This method sends the POST command to the news server. Not all servers permit clients to post articles. The client application is responsible for generating the message headers as well as the body of the message. News articles conform to the same general characteristics of an email message.

The **CloseArticle** method must be called once the contents of the article has been written to the server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

CNntpClient::CreateSecurityCredentials Method

```
BOOL CreateSecurityCredentials(
   DWORD dwProtocol,
   DWORD dwOptions,
   LPCTSTR lpszUserName,
   LPCTSTR lpszPassword,
   LPCTSTR lpszCertStore,
   LPCTSTR lpszCertName
);

BOOL CreateSecurityCredentials(
   LPCTSTR lpszCertStore,
   LPCTSTR lpszCertName
);

BOOL CreateSecurityCredentials(
   LPCTSTR lpszCertName
);
```

The **CreateSecurityCredentials** method creates security credentials for the client session.

Parameters

dwProtocol

A bitmask of supported security protocols. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_TLS	Either the TLS 1.2 or 1.3 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers which reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows

	Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwOptions

A value which specifies one or more options. This member is constructed by using a bitwise operator with any of the following values:

Value	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

lpszUserName

A null-terminated string which specifies the certificate owner's username. A value of NULL specifies that no username is required. Currently this parameter is not used and any value specified will be ignored.

lpszPassword

A null-terminated string which specifies the certificate owner's password. A value of NULL specifies that no password is required. This parameter is only used if a PKCS #12 (PFX) certificate file is specified and that certificate has been secured with a password. This value will be ignored the current user or local machine certificate store is specified.

lpszCertStore

A null-terminated string which specifies the name of the certificate store to open. A certificate store

is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A null-terminated string which specifies the name of the certificate to use. The method will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the method will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the method will return an error indicating that the certificate could not be found.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

A client application only needs to call this method if the server requires that the client provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The ***dwOptions*** parameter should be set to CREDENTIAL_STORE_FILENAME and the ***lpszCertStore*** parameter should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS #12.These certificate files typically have an extension of .pfx or .p12. If a password was specified when the certificate was

created, it must be provided in the *lpszPassword* parameter or the library will be unable to access the certificate.

Note that the *lpszUserName* and *lpszPassword* parameters are optional values which are used to access the certificate store or client certificate. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session. In most cases, these parameters can be NULL or omitted.

Example

```
pClient->CreateSecurityCredentials(
            SECURITY_PROTOCOL_DEFAULT,
            0,
            NULL,
            NULL,
            lpszCertStore,
            lpszCertName);

bConnected = pClient->Connect(lpszHostName,
                              NNTP_PORT_SECURE,
                              NNTP_TIMEOUT,
                              NNTP_OPTION_SECURE);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

Connect, DeleteSecurityCredentials, GetSecurityInformation, SECURITYCREDENTIALS

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNntpClient::DeleteSecurityCredentials Method

```
VOID DeleteSecurityCredentials();
```

The **DeleteSecurityCredentials** method releases the security credentials for the current session.

Parameters

None.

Return Value

None.

Remarks

This method can be used to release the memory allocated to the client or server credentials after a secure connection has been terminated. The security credentials are released when the class destructor is called, so it is normally not required that the application explicitly call this method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CreateSecurityCredentials

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNntpClient::DetachHandle Method

```
HCLIENT DetachHandle();
```

The **DetachHandle** method detaches the client handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the client handle associated with the current instance of the class object. If there is no active client session, the value INVALID_CLIENT will be returned.

Remarks

This method is used to detach a client handle created by the class for use with the SocketTools API. Once the client handle is detached from the class, no other class member functions may be called. Note that the handle must be explicitly released at some later point by the process or a resource leak will occur.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

See Also

AttachHandle, GetHandle

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNntpClient::DisableEvents Method

```
INT DisableEvents();
```

The **DisableEvents** method disables the event notification mechanism, preventing subsequent event notification messages from being posted to the application's message queue.

This method has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **DisableEvents** method is used to disable event message posting for the specified client session. Although this will immediately prevent any new events from being generated, it is possible that messages could be waiting in the message queue. Therefore, an application must be prepared to handle client event messages after this method has been called.

This method is automatically called if the client has event notification enabled, and the **Disconnect** method is called. The same issues regarding outstanding event messages also applies in this situation, requiring that the application handle event messages that may reference a client handle that is no longer valid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

See Also

EnableEvents, RegisterEvent

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNntpClient::DisableTrace Method

```
BOOL DisableTrace();
```

The **DisableTrace** method disables the logging of network function calls.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, a value of zero is returned.

Remarks

This method will disable output to the log file for the current thread or process, depending on the flags used when logging was enabled. If this method is not called, the resources that were allocated for the logging session will be released when the process ends.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

See Also

EnableTrace

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNntpClient::Disconnect Method

```
VOID Disconnect();
```

The **Disconnect** method terminates the connection with the server, closing the socket and releasing the memory allocated for the client session.

Parameters

None.

Return Value

None.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

Connect, IsConnected

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNntpClient::EnableEvents Method

```
INT EnableEvents(
   HWND hEventWnd,
   UINT uEventMsg
);
```

The **EnableEvents** method enables event notifications using Windows messages.

This method has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Applications should use the **RegisterEvent** method to register an event handler which is invoked when an event occurs.

Parameters

hEventWnd

Handle to the window which will receive the client notification messages. This parameter must specify a valid window handle. If a NULL handle is specified, event notification will be disabled.

uEventMsg

The message that is received when a client event occurs. This value must be greater than 1024.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **EnableEvents** method is used to request that notification messages be posted to the specified window whenever a client event occurs. This allows an application to monitor the status of different client operations, such as a file transfer.

The *wParam* argument will contain the client handle, the low word of the *lParam* argument will contain the event ID, and the high word will contain any error code. If no error has occurred, the high word will always have a value of zero. The following events may be generated:

Value	Description
NNTP_EVENT_CONNECT	The connection to the server has completed. The high word of the *lParam* parameter should be checked, since this notification message will be posted if an error has occurred.
NNTP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
NNTP_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
NNTP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This

	event is only generated if the client is in asynchronous mode.
NNTP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
NNTP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
NNTP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.
NNTP_EVENT_PROGRESS	The client is in the process of sending or receiving a file on the data channel. This event is called periodically during a transfer so that the client can update any user interface components such as a status control or progress bar.

It is not required that the client be placed in asynchronous mode in order to receive command and progress event notifications. To disable event notification, call the **DisableEvents** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

See Also

DisableEvents, RegisterEvent

CNntpClient::EnableTrace Method

```
BOOL EnableTrace(
   LPCTSTR lpszTraceFile,
   DWORD dwTraceFlags
);
```

The **EnableTrace** method enables the logging of network function calls to a file.

Parameters

lpszTraceFile

A null-terminated string which specifies the name of the logfile which will be appended to or created. It is recommended that this file always specify an absolute path to avoid any ambiguity. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
TRACE_INFO	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
TRACE_ERROR	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
TRACE_HEXDUMP	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
TRACE_TRUNCATE	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for

	multithreaded applications that are using worker threads.

Return Value

If the method succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the log file cannot be created.

Remarks

Logging is enabled and disabled at the thread or process level, depending on the flags passed to this method, and is not associated with a specific class instance. When logging is enabled, the information is appended to the specified file. If the file does not exist, it will be created. To limit the size of the file, enable and disable logging only around those sections of code that you wish to debug. If you do not provide a full path to the file, it will be relative to the current working directory for the process. This can produce unexpected results in multithreaded applications because the current directory is global to the entire process and can be changed by any thread at any time.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

The TRACE_HEXDUMP option can generate very large files because it includes all of the data exchanged between your application and the remote host. The TRACE_TRUNCATE option is only evaluated when logging is first enabled for a thread or process. If logging is already active, specifying this option will have no effect.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "**0x**". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxxx:xxxx::xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, a connection is being made to a system with the IPv4 address 192.0.0.1 on port 1234.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

CNntpClient::FreezeEvents Method

```
INT FreezeEvents(
   BOOL bFreeze
);
```

The **FreezeEvents** method is used to suspend and resume event handling by the client.

Parameters

bFreeze

A non-zero value specifies that event handling should be suspended by the client. A zero value specifies that event handling should be resumed.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

This method should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all client events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if the client has suspended event handling, and four read events occur, once event handling is resumed only one of those read events will be posted to the client. This prevents the application from being flooded by a potentially large number of queued events.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

CNntpClient::GetArticle Method

```
INT GetArticle(
   LONG nArticleId,
   LPBYTE lpBuffer,
   LPDWORD lpdwLength
);

INT GetArticle(
   LONG nArticleId,
   HGLOBAL *lpBuffer,
   LPDWORD lpdwLength
);

INT GetArticle(
   LONG nArticleId,
   CString& strBuffer
);

INT GetArticle(
   LPCTSTR lpszMessageId,
   LPBYTE lpBuffer,
   LPDWORD lpdwLength
);

INT GetArticle(
   LPCTSTR lpszMessageId,
   HGLOBAL *lpBuffer,
   LPDWORD lpdwLength
);

INT GetArticle(
   LPCTSTR lpszMessageId,
   CString& strBuffer
);
```

The **GetArticle** method retrieves the specified article and copies the contents to a local buffer.

Parameters

nArticleId

An integer value which specifies the number of the article to retrieve from the server. This value must be greater than zero. Overloaded versions of this method also support article IDs that are 64-bit integers.

lpszMessageId

A null-terminated string which specifies the message ID of the article to retrieve from the server. This parameter cannot be NULL or specify an empty string.

lpBuffer

A buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the method returns.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpBuffer* parameter. If the *lpBuffer* parameter points to a global memory handle, the length value should be initialized to zero. When the method returns,

this value will be updated with the actual length of the file that was downloaded.

Return Value

If the method succeeds, the return value is the server result code. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetArticle** method is used to retrieve an article from the server and copy it into a local buffer. The method may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the contents of the article. In this case, the *lpBuffer* parameter will point to the buffer that was allocated, the value that the *lpdwLength* parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the *lpBuffer* parameter point to a global memory handle which will contain the article data when the method returns. In this case, the value that the *lpdwLength* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the method must be freed by the application, otherwise a memory leak will occur. See the example code below.

This method will cause the current thread to block until the complete article has been retrieved, a timeout occurs or the operation is canceled. During the transfer, the NNTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **EnableEvents**, or by registering a callback function using the **RegisterEvent** method.

To determine the current status of a transfer while it is in progress, use the **GetTransferStatus** method.

Example

```
HGLOBAL hgblBuffer = (HGLOBAL)NULL;
LPBYTE lpBuffer = (LPBYTE)NULL;
DWORD cbBuffer = 0;

// Return the article into block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgblBuffer parameter
nResult = pClient->GetArticle(nArticleId, &hgblBuffer, &cbBuffer);

if (nResult != NNTP_ERROR)
{
    // Lock the global memory handle, returning a pointer to the
    // article text
    lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

Unicode: Implemented as Unicode and ANSI versions

CNntpClient::GetArticleHeaders Method

```
INT GetArticleHeaders(
   LONG nArticleId,
   LPBYTE lpHeaders,
   LPDWORD lpdwLength
);

INT GetArticleHeaders(
   LONG nArticleId,
   HGLOBAL *lpHeaders,
   LPDWORD lpdwLength
);

INT GetArticleHeaders(
   LONG nArticleId,
   CString& strHeaders
);
```

The **GetArticleHeaders** method retrieves the headers for the specified article from the server.

Parameters

nArticleId

Number of article to retrieve from the server. This value must be greater than zero. Overloaded versions of this method also support article IDs that are 64-bit integers.

lpHeaders

A buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the method returns.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the ***lpHeaders*** parameter. If the ***lpHeaders*** parameter points to a global memory handle, the length value should be initialized to zero. When the method returns, this value will be updated with the actual length of the message that was downloaded.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetArticleHeaders** method is used to retrieve an article header block from the server and copy it into a local buffer. The method may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the contents of the file. In this case, the ***lpHeaders*** parameter will point to the buffer that was allocated, the value that the ***lpdwLength*** parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the ***lpHeaders*** parameter point to a global memory handle which will contain the message headers when the method returns. In this case, the value that the ***lpdwLength*** parameter points to must be initialized to zero. It is important to note that the memory handle returned by the method must be freed by the application, otherwise a memory leak will occur.

This method will cause the current thread to block until the transfer completes, a timeout occurs or

the transfer is canceled. During the transfer, the NNTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **EnableEvents**, or by registering a callback function using the **RegisterEvent** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

CNntpClient::GetArticleMessageId Method

```
INT GetArticleMessageId(
   LONG nArticleId,
   LPTSTR lpszMessageId,
   INT cbMessageId
);

INT GetArticleMessageId(
   LONG nArticleId,
   CString& strMessageId
);
```

The **GetArticleMessageId** method returns the message identifier for the specified article in the current newsgroup.

Parameters

nArticleId

Article number to retrieve the message identifier for. The value may be zero, in which case the current article number is used.

lpszMessageId

Pointer to a string buffer which will contain the message identifier for the specified article.

cbMessageId

Maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the method succeeds, the return value is the length of the message identifier string. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The message identifier is a string which can uniquely identify the message on the news server. This value may be used to retrieve the contents of the article.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetMessageIdArticle, ListArticles

CNntpClient::GetArticleRange Method

```
BOOL GetArticleRange(
   LONG *lpnFirstArticle,
   LONG *lpnLastArticle,
   LONG *lpnArticleCount
);

BOOL GetArticleRange(
   ULONGLONG *lpnFirstArticle,
   ULONGLONG *lpnLastArticle
   ULONGLONG *lpnArticleCount
);
```

The **GetArticleRange** method returns the first and last article numbers for the currently selected newsgroup.

Parameters

lpnFirstArticle

Pointer to an integer that will contain the first article number in the currently selected newsgroup. If this parameter is NULL, it will be ignored.

lpnLastArticle

Pointer to an integer that will contain the last article number in the currently selected newsgroup. If this parameter is NULL, it will be ignored.

lpnArticleCount

Pointer to an integer that will contain the total number of articles in currently selected newsgroup. If this parameter is NULL, it will be ignored.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

It is possible that there will be gaps in the articles within the range of the first and last articles in the newsgroup. This may be due to a message being canceled or expired. If the server can potentially return very large ID values, it is recommended your application use ULONGLONGs (64-bit unsigned integers) instead of LONGs (32-bit signed integers) to store article numbers.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

See Also

CNntpClient::GetCurrentArticle Method

```
BOOL GetCurrentArticle(
   LONG *lpnArticleId
);

BOOL GetCurrentArticle(
   ULONGLONG *lpnArticleId
);
```

The **GetCurrentArticle** method returns the current article number for the currently selected newsgroup.

Parameters

lpnArticleId

Pointer to an integer variable that will contain the current article number when the method returns.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

If the server can potentially return very large ID values, it is recommended your application use ULONGLONGs (64-bit unsigned integers) instead of LONGs (32-bit signed integers) to store article numbers.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

CNntpClient::GetCurrentDate Method

```
INT GetCurrentDate(
   LPTSTR lpszDate,
   INT nMaxLength
);

INT GetCurrentDate(
   CString& strDate
);
```

The **GetCurrentDate** method copies the current date and time to the specified buffer in a format that is commonly used in news articles. This date format should be used in all date-related fields in the message header.

Parameters

lpszDate

Pointer to a string buffer that will contain the current date and time when the method returns.

nMaxLength

The maximum number of characters that can be copied into the string buffer.

Return Value

If the method succeeds, the return value is the number of characters copied into the buffer, not including the null-terminator. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The date value that is returned is adjusted for the local timezone.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

CNntpClient::GetErrorString Method

```
INT GetErrorString(
   DWORD dwErrorCode,
   LPTSTR lpszDescription,
   INT nMaxLength
);

INT GetErrorString(
   DWORD dwErrorCode,
   CString& strDescription
);
```

The **GetErrorString** method is used to return a description of a specific error code. Typically this is used in conjunction with the **GetLastError** method for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

The buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length. An alternate form of the method accepts a **CString** variable which will contain the error description.

nMaxLength

The maximum number of characters that may be copied into the description buffer.

Return Value

If the method succeeds, the return value is the length of the description string. If the method fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the method is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

CNntpClient::GetFirstArticle Method

```
BOOL GetFirstArticle(
   LPNEWSARTICLE lpArticle
);

BOOL GetFirstArticle(
   LPNEWSARTICLEEX lpArticle
);
```

The **GetFirstArticle** method returns information about the first article in the currently selected newsgroup.

Parameters

lpArticle

A pointer to a NEWSARTICLE or NEWSARTICLEEX structure which will contain information about the first article in the currently selected directory. If the server can potentially return very large article IDs, it is recommended that you use the **NEWSARTICLEEX** structure.

Return Value

If the method succeeds, the return value is non-zero. If there are no articles in the current newsgroup, or the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetFirstArticle** method returns information about the first article in the currently selected newsgroup. This method is used in conjunction with the **GetNextArticle** method to enumerate all of the articles in the newsgroup. Typically this is used to provide the user with a list of articles to access.

While the articles in the newsgroup are being listed, the client cannot retrieve the contents of a specific article. For example, the **GetArticle** method cannot be called while inside a loop calling **GetNextArticle**. The client should store those articles which it wants to retrieve in an array, and then once all of the articles have been listed, it can begin calling **NttpGetArticle** for each article number to retrieve the article text.

The date and time that the article was posted is returned in the *stPosted* member of the NEWSARTICLE structure. This value is returned in Universal Coordinated Time (UTC) and can be converted to local time using the **SystemTimeToTzSpecificLocalTime** function.

Example

```
// List all articles in the current group
if (pClient->ListArticles() == NNTP_ERROR)
    pClient->ShowError();
else
{
    NEWSARTICLE newsArticle;
    BOOL bResult;

    // Get each article in the current newsgroup, printing the article
    // number and the subject of the article
    bResult = pClient->GetFirstArticle(&newsArticle);
    while (bResult)
    {
        _tprintf(_T("%ld %s\n"), newsArticle.nArticleId, newsArticle.szSubject);
        bResult = pClient->GetNextArticle(&newsArticle);
```

```
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetArticle, GetFirstGroup, GetNextArticle, GetNextGroup, ListArticles, ListGroups, SelectGroup, NEWSARTICLE, NEWSGROUP

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNntpClient::GetFirstGroup Method

```
BOOL GetFirstGroup(
   LPNEWSGROUP lpGroup
);

BOOL GetFirstGroup(
   LPNEWSGROUPEX lpGroup
);
```

The **GetFirstGroup** method returns information about the first available newsgroup.

Parameters

lpGroup

A pointer to a NEWSGROUP or NEWSGROUPEX structure which will contain information about the first available newsgroup. If the server can potentially return very large article IDs, it is recommended that you use the **NEWSGROUPEX** structure.

Return Value

If the method succeeds, the return value is non-zero. If there are no newsgroups available, or the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetFirstGroup** method returns information about the first newsgroup on the server. This method is used in conjunction with the **GetNextGroup** method to enumerate all of the available newsgroups. Typically this is used to provide the user with a list of newsgroups to select.

While the newsgroups are being listed, the client cannot select a newsgroup or retrieve the contents of a specific article. The client should store those newsgroups which it wants to retrieve articles from, and then once all of the newsgroups have been listed, it can then select each newsgroup and retrieve the available articles from that group.

Note that if no newsgroups are returned by the server, it may indicate that it requires the client to authenticate itself prior to requesting a list of groups or articles.

Example

```
// List all available newsgroups
if (pClient->ListGroups() == NNTP_ERROR)
    pClient->ShowError();
else
{
    NEWSGROUP newsGroup;
    BOOL bResult;

    // Get each newsgroup, printing the article range and
    // the name of the group
    bResult = pClient->GetFirstGroup(&newsGroup);
    while (bResult)
    {
        printf("%ld %ld %s\n", newsGroup.nFirstArticle,
                               newsGroup.nLastArticle,
                               newsGroup.szName);
        bResult = pClient->GetNextGroup(&newsGroup);
    }
```

```
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

CNntpClient::GetGroupName Method

```
INT GetGroupName(
   LPTSTR lpszGroupName,
   INT nMaxLength
);

INT GetGroupName(
   CString& strGroupName
);
```

The **GetGroupName** method returns the name of the currently selected newsgroup.

Parameters

lpszGroupName

Pointer to a string buffer that will contain the name of the currently selected newsgroup.

nMaxLength

The maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the method succeeds, the return value is the length of the newsgroup name. If no newsgroup has been selected, the method will return a value of zero. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetGroupTitle, ListGroups, SelectGroup

CNntpClient::GetGroupTitle Method

```
INT GetGroupTitle(
   LPTSTR lpszGroupTitle,
   INT nMaxLength
);

INT GetGroupTitle(
   CString& strGroupTitle
);
```

The **GetGroupTitle** method returns a description of the currently selected newsgroup.

Parameters

lpszGroupTitle

Pointer to a string buffer that will contain a description of the currently selected newsgroup.

nMaxLength

The maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the method succeeds, the return value is the length of the description. If no newsgroup has been selected, the method will return a value of zero. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The news server must support the XGTITLE command so that the group description can be obtained when the newsgroup is selected. If this command is not recognized, then no description will be returned.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

CNntpClient::GetHandle Method

```
HCLIENT GetHandle();
```

The **GetHandle** method returns the client handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the client handle associated with the current instance of the class object. If there is no active client session, the value INVALID_CLIENT will be returned.

Remarks

This method is used to obtain the client handle created by the class for use with the SocketTools API.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNntpClient::GetLastError Method

```
DWORD GetLastError();

DWORD GetLastError(
   CString& strDescription
);
```

Parameters

strDescription

A string which will contain a description of the last error code value when the method returns. If no error has been set, or the last error code has been cleared, this string will be empty.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **SetLastError** method. The Return Value section of each reference page notes the conditions under which the method sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **GetLastError** method immediately when a method's return value indicates that an error has occurred. That is because some methods call **SetLastError**(0) when they succeed, clearing the error code set by the most recently failed method.

Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or NNTP_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

The description of the error code is the same string that is returned by the **GetErrorString** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

CNntpClient::GetMessageIdArticle Method

```
BOOL GetMessageIdArticle(
   LPCTSTR lpszMessageId,
   LONG *lpnMessageId
);

BOOL GetMessageIdArticle(
   LPCTSTR lpszMessageId,
   ULONGLONG *lpnMessageId
);
```

The **GetMessageIdArticle** method returns the article number associated with the specified message identifier in the current newsgroup.

Parameters

lpszMessageId

The message identifier string.

lpnArticleId

Pointer to an integer variable that will contain the article number associated with the message ID.

Return Value

If the method succeeds, the return value is the article number. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

If the server can potentially return very large ID values, it is recommended your application use ULONGLONGs (64-bit unsigned integers) instead of LONGs (32-bit signed integers) to store article numbers.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

CNntpClient::GetNextArticle Method

```
BOOL GetNextArticle(
   LPNEWSARTICLE lpArticle
);

BOOL GetNextArticle(
   LPNEWSARTICLEEX lpArticle
);
```

The **GetNextArticle** method returns information about the next article in the currently selected newsgroup.

Parameters

lpArticle

A pointer to a NEWSARTICLE or NEWSARTICLEEX structure which will contain information about the next available article in the currently selected directory. If the server can potentially return very large article IDs, it is recommended that you use the **NEWSARTICLEEX** structure.

Return Value

If the method succeeds, the return value is non-zero. If there are no more articles in the current newsgroup, or the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetNextArticle** method returns information about the next available article in the currently selected newsgroup. This method is used in conjunction with the **GetFirstArticle** method to enumerate all of the articles in the newsgroup. Typically this is used to provide the user with a list of articles to access.

While the articles in the newsgroup are being listed, the client cannot retrieve the contents of a specific article. For example, the **GetArticle** method cannot be called while inside a loop calling **GetNextArticle**. The client should store those articles which it wants to retrieve in an array, and then once all of the articles have been listed, it can begin calling **NttpGetArticle** for each article number to retrieve the article text.

Example

```
// List all articles in the current group
if (pClient->ListArticles() == NNTP_ERROR)
    pClient->ShowError();
else
{
    NEWSARTICLE newsArticle;
    BOOL bResult;

    // Get each article in the current newsgroup, printing the article
    // number and the subject of the article
    bResult = pClient->GetFirstArticle(&newsArticle);
    while (bResult)
    {
        _tprintf(_T("%ld %s\n"), newsArticle.nArticleId, newsArticle.szSubject);
        bResult = pClient->GetNextArticle(&newsArticle);
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetArticle, GetFirstArticle, GetFirstGroup, GetNextGroup, ListArticles, ListGroups, SelectGroup, NEWSARTICLE, NEWSGROUP

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNntpClient::GetNextGroup Method

```
BOOL GetNextGroup(
   LPNEWSGROUP lpGroup
);

BOOL GetNextGroup(
   LPNEWSGROUPEX lpGroup
);
```

The **GetNextGroup** method returns information about the next available newsgroup.

Parameters

lpGroup

A pointer to a NEWSGROUP or NEWSGROUPEX structure which will contain information about the next available newsgroup. If the server can potentially return very large article IDs, it is recommended that you use the **NEWSGROUPEX** structure.

Return Value

If the method succeeds, the return value is non-zero. If there are no more newsgroups available, or the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetNextGroup** method returns information about the next newsgroup on the server. This method is used in conjunction with the **GetFirstGroup** method to enumerate all of the available newsgroups. Typically this is used to provide the user with a list of newsgroups to select.

While the newsgroups are being listed, the client cannot select a newsgroup or retrieve the contents of a specific article. The client should store those newsgroups which it wants to retrieve articles from, and then once all of the newsgroups have been listed, it can then select each newsgroup and retrieve the available articles from that group.

Example

```
// List all available newsgroups
if (pClient->ListGroups() == NNTP_ERROR)
    pClient->ShowError();
else
{
    NEWSGROUP newsGroup;
    BOOL bResult;

    // Get each newsgroup, printing the article range and
    // the name of the group
    bResult = pClient->GetFirstGroup(&newsGroup);
    while (bResult)
    {
        printf("%ld %ld %s\n", newsGroup.nFirstArticle,
                               newsGroup.nLastArticle,
                               newsGroup.szName);
        bResult = pClient->GetNextGroup(&newsGroup);
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

CNntpClient::GetResultCode Method

```
INT GetResultCode();
```

The **GetResultCode** method reads the result code returned by the server in response to a command. The result code is a three-digit numeric code, and indicates if the operation succeeded, failed or requires additional action by the client.

Parameters

None.

Return Value

If the method succeeds, the return value is the result code. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

Result codes are three-digit numeric values returned by the server. They may be broken down into the following ranges:

Value	Description
100-199	Positive preliminary result. This indicates that the requested action is being initiated, and the client should expect another reply from the server before proceeding.
200-299	Positive completion result. This indicates that the server has successfully completed the requested action.
300-399	Positive intermediate result. This indicates that the requested action cannot complete until additional information is provided to the server.
400-499	Transient negative completion result. This indicates that the requested action did not take place, but the error condition is temporary and may be attempted again.
500-599	Permanent negative completion result. This indicates that the requested action did not take place.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

See Also

Command, GetResultString

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNntpClient::GetResultString Method

```
INT GetResultString(
   LPTSTR lpszResult,
   INT cbResult
);

INT GetResultString(
   CString& strResult
);
```

The **GetResultString** method returns the last message sent by the server along with the result code.

Parameters

lpszResult

The buffer that will contain the result string returned by the server. An alternate form of the method accepts a **CString** argument which will contain the result string returned by the server.

cbResult

The maximum number of characters that may be copied into the result string buffer, including the terminating null character.

Return Value

If the method succeeds, the return value is the length of the result string. If a value of zero is returned, this means that no result string was sent by the server. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetResultString** method is most useful when an error occurs because the server will typically include a brief description of the cause of the error. This can then be parsed by the application or displayed to the user. The result string is updated each time the client sends a command to the server and then calls **GetResultCode** to obtain the result code for the operation.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

Command, GetResultCode

CNntpClient::GetSecurityInformation Method

```
BOOL GetSecurityInformation(
   LPSECURITYINFO lpSecurityInfo
);
```

The **GetSecurityInformation** method returns security protocol, encryption and certificate information about the current client connection.

Parameters

lpSecurityInfo

A pointer to a SECURITYINFO structure which contains information about the current client connection. The *dwSize* member of this structure must be initialized to the size of the structure before passing the address of the structure to this method.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method is used to obtain security related information about the current client connection to the server. It can be used to determine if a secure connection has been established, what security protocol was selected, and information about the server certificate. Note that a secure connection has not been established, the *dwProtocol* structure member will contain the value SECURITY_PROTOCOL_NONE.

Example

The following example notifies the user if the connection is secure or not:

```
SECURITYINFO securityInfo;
securityInfo.dwSize = sizeof(SECURITYINFO);

if (pClient->GetSecurityInformation(&securityInfo))
{
    if (securityInfo.dwProtocol == SECURITY_PROTOCOL_NONE)
    {
        MessageBox(NULL, _T("The connection is not secure"),
                         _T("Connection"), MB_OK);
    }
    else
    {
        if (securityInfo.dwCertStatus == SECURITY_CERTIFICATE_VALID)
        {
            MessageBox(NULL, _T("The connection is secure"),
                             _T("Connection"), MB_OK);
        }
        else
        {
            MessageBox(NULL, _T("The server certificate not valid"),
                             _T("Connection"), MB_OK);
        }
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

Connect, CreateSecurityCredentials, SECURITYINFO

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNntpClient::GetStatus Method

```
INT GetStatus();
```

The **GetStatus** method the current status of the client session.

Parameters

None.

Return Value

If the method succeeds, the return value is the client status code. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetStatus** method returns a numeric code which identifies the current state of the client session. The following values may be returned:

Value	Description
NNTP_STATUS_UNUSED	No connection has been established.
NNTP_STATUS_IDLE	The client is current idle and not sending or receiving data.
NNTP_STATUS_CONNECT	The client is establishing a connection with the server.
NNTP_STATUS_READ	The client is reading data from the server.
NNTP_STATUS_WRITE	The client is writing data to the server.
NNTP_STATUS_DISCONNECT	The client is disconnecting from the server.

In a multithreaded application, any thread in the current process may call this method to obtain status information for the specified client session. To obtain status information about a file transfer, use the **GetTransferStatus** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

See Also

IsBlocking, IsInitialized, IsReadable, IsWritable

CNntpClient::GetTimeout Method

```
INT GetTimeout();
```

The **GetTimeout** method returns the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the method will fail and return to the caller.

Parameters

None.

Return Value

If the method succeeds, the return value is the timeout period in seconds. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The timeout value is only used with blocking client connections. A value of zero indicates that the default timeout period of 20 seconds should be used.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

See Also

Connect, IsReadable, IsWritable, Read, SetTimeout, Write

CNntpClient::GetTransferStatus Method

```
INT GetTransferStatus(
   LPNNTPTRANSFERSTATUS lpStatus
);

INT GetTransferStatus(
   LPNNTPTRANSFERSTATUSEX lpStatus
);
```

The **GetTransferStatus** method returns information about the current data transfer in progress.

Parameters

lpStatus

A pointer to an NNTPTRANSFERSTATUS or NNTPTRANSFERSTATUSEX structure which contains information about the status of the current data transfer. If the server can potentially return very large article IDs, it is recommended that you use the **NNTPTRANSFERSTATUSEX** structure.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetTransferStatus** method returns information about the current data transfer, including the average number of bytes transferred per second and the estimated amount of time until the transfer completes. If no article is currently being retrieved or submitted to the server, this function will return the status of the last successful data transfer made by the client.

In a multithreaded application, any thread in the current process may call this method to obtain status information for the specified client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

EnableEvents, GetStatus, RegisterEvent

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNntpClient::IsBlocking Method

```
BOOL IsBlocking();
```

The **IsBlocking** method is used to determine if the client is currently performing a blocking operation.

Parameters

None.

Return Value

If the client is performing a blocking operation, the method returns a non-zero value. If the client is not performing a blocking operation, or the client handle is invalid, the method returns zero.

Remarks

Because a blocking operation can allow the application to be re-entered (for example, by pressing a button while the operation is being performed), it is possible that another blocking method may be called while it is in progress. Since only one thread of execution may perform a blocking operation at any one time, an error would occur. The **IsBlocking** method can be used to determine if the client is already blocked, and if so, take some other action (such as warning the user that they must wait for the operation to complete).

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

Cancel, GetStatus, IsConnected, IsInitialized, IsReadable, IsWritable, Read, Write

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNntpClient::IsConnected Method

```
BOOL IsConnected();
```

The **IsConnected** method is used to determine if the client is currently connected to a server.

Parameters

None.

Return Value

If the client is connected to a server, the method returns a non-zero value. If the client is not connected, or the client handle is invalid, the method returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

See Also

GetStatus, IsBlocking, IsInitialized, IsReadable, IsWritable

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNntpClient::IsInitialized Method

```
BOOL IsInitialized();
```

The **IsInitialized** method returns whether or not the class object has been successfully initialized.

Parameters

None.

Return Value

This method returns a non-zero value if the class object has been successfully initialized. A return value of zero indicates that the runtime license key could not be validated or the networking library could not be loaded by the current process.

Remarks

When an instance of the class is created, the class constructor will attempt to initialize the component with the runtime license key that was created when SocketTools was installed. If the constructor is unable to validate the license key or load the networking libraries, this initialization will fail.

If SocketTools was installed with an evaluation license, the application cannot be redistributed to another system. The class object will fail to initialize if the application is executed on another system, or if the evaluation period has expired. To redistribute your application, you must purchase a development license which will include the runtime key that is needed to redistribute your software to other systems. Refer to the Developer's Guide for more information.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

See Also

CNntpClient, IsBlocking, IsConnected

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNntpClient::IsReadable Method

```
BOOL IsReadable(
   INT nTimeout,
   LPDWORD lpdwAvail
);
```

The **IsReadable** method is used to determine if data is available to be read from the server.

Parameters

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

lpdwAvail

A pointer to an unsigned integer which will contain the number of bytes available to read. This parameter may be NULL if this information is not required.

Return Value

If the client can read data from the server within the specified timeout period, the method returns a non-zero value. If the client cannot read any data, the method returns zero.

Remarks

On some platforms, this value will not exceed the size of the receive buffer (typically 64K bytes). Because of differences between TCP/IP stack implementations, it is not recommended that your application exclusively depend on this value to determine the exact number of bytes available. Instead, it should be used as a general indicator that there is data available to be read.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

See Also

GetStatus, IsBlocking, IsConnected, IsInitialized, IsWritable, Write

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNntpClient::IsWritable Method

```
BOOL IsWritable(
   INT nTimeout
);
```

The **IsWritable** method is used to determine if data can be written to the server.

Parameters

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

Return Value

If the client can write data to the server within the specified timeout period, the method returns a non-zero value. If the client cannot write any data, the method returns zero.

Remarks

Although this method can be used to determine if some amount of data can be sent to the remote process it does not indicate the amount of data that can be written without blocking the client. In most cases, it is recommended that large amounts of data be broken into smaller logical blocks, typically some multiple of 512 bytes in length.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

See Also

GetStatus, IsBlocking, IsConnected, IsInitialized, IsReadable, Write

CNntpClient::ListArticles Method

```
INT ListArticles(
   LONG nFirstArticle,
   LONG nLastArticle
);

INT ListArticles(
   ULONGLONG nFirstArticle,
   ULONGLONG nLastArticle
);
```

The **ListArticles** method returns a list of articles in the currently selected newsgroup, within the specified article range.

Parameters

nFirstArticle

The first newsgroup article to be returned in the list. If this value is -1, the list will begin with the first available article in the newsgroup.

nLastArticle

The last newsgroup article to be returned in the list. If the value is -1, the list will end with the last available article in the newsgroup.

Return Value

If the method succeeds, the return value is the server result code. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

It is possible that there will be gaps in the articles within the range of the first and last articles in the newsgroup. This may be due to a message being canceled or expired. Use the **GetFirstArticle** and **GetNextArticle** methods to read the list of articles returned by the server. If the server can potentially return very large ID values, it is recommended your application use ULONGLONGs (64-bit unsigned integers) instead of LONGs (32-bit signed integers) to store article numbers.

Example

```
// List all articles in the current group
if (pClient->ListArticles() == NNTP_ERROR)
    pClient->ShowError();
else
{
    NEWSARTICLE newsArticle;
    BOOL bResult;

    // Get each article in the current newsgroup, printing the article
    // number and the subject of the article
    bResult = pClient->GetFirstArticle(&newsArticle);
    while (bResult)
    {
        printf("%ld %s %s\n", newsArticle.nArticleId, newsArticle.szSubject);
        bResult = pClient->GetNextArticle(&newsArticle);
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetArticleRange, GetCurrentArticle, GetFirstArticle, GetNextArticle, ListGroups

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNntpClient::ListGroups Method

```
INT ListGroups(
   LPCTSTR lpszLastUpdated,
   BOOL bLocalTime
);
```

The **ListGroups** method instructs the server to begin sending a list of newsgroups that were created since the specified date.

Parameters

lpszLastUpdated

Pointer to a string which specifies the date and time that the list of newsgroups were last retrieved from the server. This parameter may be NULL or an empty string, in which case all available newsgroups will be listed by the server.

bLocalTime

A boolean value which indicates if the time specified in the *lpszLastUpdated* parameter is for the current timezone. If the value is non-zero, the time is assumed to be in the local timezone. If the value is zero, the time is assumed to be in Coordinated Universal Time (UTC).

Return Value

If the method succeeds, the return value is the server result code. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **ListGroups** method is used in conjunction with the **GetFirstGroup** and **GetNextGroup** methods to enumerate all of the newsgroups that were added to the server since a specific date and time. Typically this is used to provide the user with a list of updated newsgroups to select. To list all of the newsgroups available on the server, omit the arguments to this method.

While the newsgroups are being listed, the client cannot select a newsgroup or retrieve the contents of a specific article. The client should store those newsgroups which it wants to retrieve articles from, and then once all of the newsgroups have been listed, it can then select each newsgroup and retrieve the available articles from that group.

Example

```
LPCTSTR lpszUpdated = _T("1/1/2004 12:00 AM");

// List all newsgroups that were added after a specific date
if (pClient->ListGroups(lpszUpdated, TRUE) == NNTP_ERROR)
    pClient->ShowError();
else
{
    NEWSGROUP newsGroup;
    BOOL bResult;

    // Get each newsgroup, printing the article range and
    // the name of the group
    bResult = pClient->GetFirstGroup(&newsGroup);
    while (bResult)
    {
        printf("%ld %ld %s\n", newsGroup.nFirstArticle,
```

```
                                newsGroup.nLastArticle,
                                newsGroup.szName);
            bResult = pClient->GetNextGroup(&newsGroup);
        }
    }
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

CNntpClient::OpenArticle Method

```
INT OpenArticle(
   LONG nArticleId
);

INT OpenArticle(
   LPCTSTR lpszMessageId
);
```

The **OpenArticle** method opens the specified article in the currently selected newsgroup.

Parameters

nArticleId

Number that specifies which article in the current newsgroup to retrieve. This value may be zero, which specifies that the current article should be returned.

lpszMessageId

Pointer to a string which contains the message identifier for the article in the current newsgroup.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNntpClient::OpenNextArticle Method

```
INT OpenNextArticle();
```

The **OpenNextArticle** method opens the next available article in the current newsgroup.

Parameters

None.

Return Value

If the method succeeds, the return value is the server result code. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

CNntpClient::OpenPreviousArticle Method

```
INT OpenPreviousArticle();
```

The **OpenPreviousArticle** method opens the previous article in the current newsgroup.

Parameters

None.

Return Value

If the method succeeds, the return value is the server result code. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

CNntpClient::PostArticle Method

```
INT PostArticle(
   LPCTSTR lpBuffer,
   DWORD dwLength
);
```

The **PostArticle** method post the contents of the specified buffer to the server as a new article in the current newsgroup.

Parameters

lpBuffer

A pointer to a character buffer which contains the article to be posted to the currently selected newsgroup.

dwLength

Specifies the length of the string which contains the article. If this parameter is -1, the actual length of the string is calculated by searching the buffer for a terminating null byte.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **PostArticle** method is used to post the contents of the specified buffer to the server as a new article in the current newsgroup. Not all newsgroups permit new articles to be posted, and some newsgroups may require that you email the article to a moderator for approval instead of posting directly to the group. It may be required that the client authenticate itself using the **Authenticate** method prior to posting the article.

A news article is similar to an email message in that it contains one or more header fields, followed by an empty line, followed by the body of the article. Each line of text should be terminated by a carriage return/linefeed sequence of characters. The Mail Message library can be used to compose a message if needed. Note that the article header must contain a header field named "Newsgroups" with a value that specifies the newsgroup or newsgroups the article is being posted to. If this header field is missing, the news server will reject the article.

This method will cause the current thread to block until the transfer has completed, a timeout occurs or the transfer is canceled. During the transfer, the HTTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **EnableEvents**, or by registering a callback function using the **RegisterEvent** method.

To determine the current status of a transfer while it is in progress, use the **GetTransferStatus** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

See Also

CNntpClient::Read Method

```
INT Read(
   LPBYTE lpBuffer,
   INT cbBuffer
);

INT Read(
   CString& strBuffer,
   INT cbBuffer
);
```

The **Read** method reads the specified number of bytes from the client socket and copies them into the buffer. The data may be of any type, and is not terminated with a null character.

Parameters

lpBuffer

Pointer to the buffer in which the data will be copied. An alternate form of this method allows a **CString** variable to be passed and data read from the socket will be returned in that string.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

Return Value

If the method succeeds, the return value is the number of bytes actually read. A return value of zero indicates that the server has closed the connection and there is no more data available to be read. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

When **Read** is called and the client is in non-blocking mode, it is possible that the method will fail because there is no available data to read at that time. This should not be considered a fatal error. Instead, the application should simply wait to receive the next asynchronous notification that data is available.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

See Also

EnableEvents, IsBlocking, IsReadable, IsWritable, RegisterEvent, Write

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNntpClient::RegisterEvent Method

```
INT RegisterEvent(
   UINT nEventId,
   NNTPEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

The **RegisterEvent** method registers an event handler for the specified event.

Parameters

nEventId

An unsigned integer which specifies which event should be registered with the specified callback function. One of the following values may be used:

Value	Description
NNTP_EVENT_CONNECT	The connection to the server has completed.
NNTP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
NNTP_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
NNTP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
NNTP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
NNTP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
NNTP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.
NNTP_EVENT_PROGRESS	The client is in the process of sending or receiving a file on the data channel. This event is called periodically during a transfer so that the client can update any user interface components such as a status control or progress bar.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **NntpEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **RegisterEvent** method associates a callback function with a specific event. The event handler is an **NntpEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

This method is typically used to register an event handler that is invoked while a news article is being uploaded or downloaded. The NNTP_EVENT_PROGRESS event will only be generated periodically during the transfer to ensure the application is not flooded with event notifications. It is guaranteed that at least one NNTP_EVENT_PROGRESS notification will occur at the beginning of the transfer, and one at the end of the transfer when it has completed.

The callback function specified by the *lpEventProc* parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

The *dwParam* parameter is commonly used to identify the class instance which is associated with the event that has occurred. Applications will cast the **this** pointer to a DWORD_PTR value when calling this function, and then the event handler will cast it back to a pointer to the class instance. This gives the handler access to the class member variables and methods.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

See Also

DisableEvents, EnableEvents, FreezeEvents, NntpEventProc

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNntpClient::Reset Method

```
INT Reset();
```

The **Reset** method resets the client state and resynchronizes with the server. This method is typically called after an unexpected error has occurred, or an operation has been canceled.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The client cannot be reset while it is in a blocked state.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

See Also

Cancel, IsBlocking

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNntpClient::SelectGroup Method

```
INT SelectGroup(
   LPCTSTR lpszGroupName
);
```

The **SelectGroup** method selects the specified newsgroup from which articles will be retrieved.

Parameters

lpszGroupName

Pointer to a string which specifies the newsgroup to be selected. This value may be NULL, in which case the current newsgroup is unchanged, but the article count is updated.

Return Value

If the method succeeds, the return value is the server result code. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

This method selects the newsgroup and obtains a description and the first and last article numbers for that group.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetGroupName, GetGroupTitle, ListGroups

CNntpClient::SetLastError Method

```
VOID SetLastError(
   DWORD dwErrorCode
);
```

The **SetLastError** method sets the last error code for the current thread. This method is typically used to clear the last error by specifying a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or NNTP_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

Applications can retrieve the value saved by this method by using the **GetLastError** method. The use of **GetLastError** is optional; an application can call the method to determine the specific reason for a method failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

See Also

GetErrorString, GetLastError, ShowError

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNntpClient::SetTimeout Method

```
INT SetTimeout(
   UINT nTimeout
);
```

The **SetTimeout** method sets the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the method will fail and return to the caller.

Parameters

nTimeout

The number of seconds to wait for a blocking operation to complete.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

See Also

CNntpClient::ShowError Method

```
INT ShowError(
   LPCTSTR lpszAppTitle,
   UINT uType,
   DWORD dwErrorCode
);
```

The **ShowError** method displays a message box which describes the specified error.

Parameters

lpszAppTitle

A null-terminated string which specifies the title of the message box that is displayed. If this argument is NULL or omitted, then the default title of "Error" will be displayed.

uType

An unsigned integer which specifies the type of message box that will be displayed. This is the same value that is used by the **MessageBox** method in the Windows API. If a value of zero is specified, then a message box with a single OK button will be displayed. Refer to that method for a complete list of options.

dwErrorCode

Specifies the error code that will be used when displaying the message box. If this argument is zero, then the last error that occurred in the current thread will be displayed.

Return Value

If the method is successful, the return value will be the return value from the **MessageBox** function. If the method fails, it will return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetErrorString, GetLastError, SetLastError

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNntpClient::StoreArticle Method

```
INT StoreArticle(
   LONG nArticleId,
   LPCTSTR lpszFileName
);
```

The **StoreMessage** method retrieves an article from the current newsgroup and stores it in a local file.

Parameters

nArticleId

Number of the article to retrieve. This value must be greater than zero.

lpszFileName

Pointer to a string which specifies the file that the article will be stored in. If the file does not exist, it will be created. If the file does exist, it will be overwritten with the contents of the article.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **StoreArticle** method provides a method of retrieving and storing an article on the local system. The contents of the article is stored as a text file, using the specified file name. This method always causes the caller to block until the entire message has been retrieved, even if the client has been put in asynchronous mode.

If event handling is enabled, the NNTP_EVENT_PROGRESS event will fire periodically during the transfer of the article to the local system. An application can determine how much of the article has been retrieved by calling the **GetTransferStatus** method.

To retrieve the message into a global memory buffer so that it can be passed to the MIME library, use the **GetArticle** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CNntpClient::Write Method

```
INT Write(
   LPBYTE lpBuffer,
   INT cbBuffer
);

INT Write(
   LPCTSTR lpszBuffer
   INT cbBuffer
);
```

The **Write** method sends the specified number of bytes to the server.

Parameters

lpBuffer

The pointer to the buffer which contains the data that is to be sent to the server. In an alternate form of the method, the pointer is to a string.

cbBuffer

The number of bytes to send from the specified buffer. This value must be greater than zero, unless a pointer to a string buffer is passed as the parameter. In that case, if the value is -1, all of the characters in the string, up to but not including the terminating null character, will be sent to the server.

Return Value

If the method succeeds, the return value is the number of bytes actually written. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The return value may be less than the number of bytes specified by the ***cbBuffer*** parameter. In this case, the data has been partially written and it is the responsibility of the client application to send the remaining data at some later point. For non-blocking clients, the client must wait for the next asynchronous notification message before it resumes sending data.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

NEWSARTICLE

This structure is used by the **GetFirstArticle** and **GetNextArticle** methods to return information about news articles.

```
typedef struct _NEWSARTICLE
{
    LONG        nArticleId;
    LONG        nBytes;
    LONG        nLines;
    TCHAR       szSubject[NNTP_MAXSUBJLEN];
    TCHAR       szAuthor[NNTP_MAXAUTHLEN];
    TCHAR       szMessageId[NNTP_MAXMSGIDLEN];
    TCHAR       szReferences[NNTP_MAXREFLEN];
    SYSTEMTIME  stPosted;
} NEWSARTICLE, *LPNEWSARTICLE;
```

Members

nArticleId

A long integer which specifies the article number.

nBytes

The length of the news article in bytes.

nLines

The length of the news article specified as the number of lines of text.

szSubject

A null-terminated string which specifies the subject of the article.

szAuthor

A null-terminated string which specifies the email address of the user who posted the article.

szMessageId

A null-terminated string which specifies the message ID for the article.

szReferences

A null-terminated string which specifies references to the article.

stPosted

A SYSTEMTIME structure which specifies when the article was posted in Universal Coordinated Time (UTC).

Remarks

If the server uses 64-bit article IDs your application should use the NEWSARTICLEEX structure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

NEWSGROUP

This structure is used by the **GetFirstGroup** and **GetNextGroup** methods to return information about the available newsgroups.

```
typedef struct _NEWSGROUP
{
    LONG        nFirstArticle;
    LONG        nLastArticle;
    DWORD       dwAccess;
    TCHAR       szName[NNTP_MAXGRPNAMLEN];
} NEWSGROUP, *LPNEWSGROUP;
```

Members

nFirstArticle

A long integer which specifies the article number of the first available article in the newsgroup.

nLastArticle

A long integer which specifies the article number of the last available article in the newsgroup. Note that posted articles may not be contiguous in the range between the first and last article numbers. Some servers may assign numbers in a different order than the articles were posted, or there may be gaps where articles have been removed.

dwAccess

An unsigned integer which specifies the access mode for the group. It may be one of the following values:

Value	Description
NNTP_GROUP_READONLY	The group is read-only and cannot be modified. Attempts to post articles to the newsgroup will result in an error.
NNTP_GROUP_READWRITE	Articles can be posted to the newsgroup. Even though a newsgroup is read-write, it may require that the client authenticate before being given permission to post articles to the server.
NNTP_GROUP_MODERATED	The newsgroup is moderated and articles can only be posted by the group moderator. To request that an article be posted to the newsgroup, you must email the message to the moderator.

szName

A null-terminated string which specifies the name of the newsgroup.

Remarks

If the server uses 64-bit article IDs your application should use the NEWSGROUPEX structure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

```
typedef struct _NEWSGROUPEX
{
    ULONGLONG   nFirstArticle;
    ULONGLONG   nLastArticle;
    DWORD       dwAccess;
    TCHAR       szName[NNTP_MAXGRPNAMLEN];
} NEWSGROUP, *LPNEWSGROUP;
```

Members

nFirstArticle

An unsigned 64-bit integer which specifies the article number of the first available article in the newsgroup.

nLastArticle

An unsigned 64-bit integer which specifies the article number of the last available article in the newsgroup. Note that posted articles may not be contiguous in the range between the first and last article numbers. Some servers may assign numbers in a different order than the articles were posted, or there may be gaps where articles have been removed.

dwAccess

An unsigned integer which specifies the access mode for the group. It may be one of the following values:

Value	Description
NNTP_GROUP_READONLY	The group is read-only and cannot be modified. Attempts to post articles to the newsgroup will result in an error.
NNTP_GROUP_READWRITE	Articles can be posted to the newsgroup. Even though a newsgroup is read-write, it may require that the client authenticate before being given permission to post articles to the server.
NNTP_GROUP_MODERATED	The newsgroup is moderated and articles can only be posted by the group moderator. To request that an article be posted to the newsgroup, you must email the message to the moderator.

szName

A null-terminated string which specifies the name of the newsgroup.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

NNTPTRANSFERSTATUS

This structure is used by the GetTransferStatus method to return information about an article transfer in progress.

```
typedef struct _NNTPTRANSFERSTATUS
{
   UINT    nArticleId;
   DWORD   dwBytesTotal;
   DWORD   dwBytesCopied;
   DWORD   dwBytesPerSecond;
   DWORD   dwTimeElapsed;
   DWORD   dwTimeEstimated;
} NNTPTRANSFERSTATUS, *LPNNTPTRANSFERSTATUS;
```

Members

nArticleId

The article ID of the current article that is being transferred. If an article is being posted, this member will be set to zero.

dwBytesTotal

The total number of bytes that will be transferred. If the article is being copied from the server to the local host, this is the size of the article on the server. If the article is being posted to the server, it is the size of article on the local system. If the article size cannot be determined, this value will be zero.

dwBytesCopied

The total number of bytes that have been copied.

dwBytesPerSecond

The average number of bytes that have been copied per second.

dwTimeElapsed

The number of seconds that have elapsed since the transfer started.

dwTimeEstimated

The estimated number of seconds until the transfer is completed. This is based on the average number of bytes transferred per second.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

NNTPTRANSFERSTATUSEX

This structure is used by the **GetTransferStatus** method to return information about an article transfer in progress. This structure is intended for use with servers that return 64-bit article IDs.

```
typedef struct _NNTPTRANSFERSTATUSEX
{
   ULONGLONG nArticleId;
   DWORD     dwBytesTotal;
   DWORD     dwBytesCopied;
   DWORD     dwBytesPerSecond;
   DWORD     dwTimeElapsed;
   DWORD     dwTimeEstimated;
} NNTPTRANSFERSTATUSEX, *LPNNTPTRANSFERSTATUSEX;
```

Members

nArticleId

An unsigned 64-bit integer that specifies the article ID of the current article that is being transferred. If an article is being posted, this value will be zero.

dwBytesTotal

An unsigned integer that specifies the total number of bytes that will be transferred. If the article is being copied from the server to the local host, this is the size of the article on the server. If the article is being posted to the server, it is the size of article on the local system. If the article size cannot be determined, this value will be zero.

dwBytesCopied

An unsigned integer that specifies the total number of bytes that have been copied.

dwBytesPerSecond

An unsigned integer that specifies the average number of bytes that have been copied per second.

dwTimeElapsed

An unsigned integer that specifies the number of seconds that have elapsed since the transfer started.

dwTimeEstimated

An unsigned integer that specifies the estimated number of seconds until the transfer is completed. This is based on the average number of bytes transferred per second.

SECURITYCREDENTIALS

The **SECURITYCREDENTIALS** structure specifies the information needed by the library to specify additional security credentials, such as a client certificate, when establishing a secure connection.

```
typedef struct _SECURITYCREDENTIALS
{
    DWORD    dwSize;
    DWORD    dwProtocol;
    DWORD    dwOptions;
    DWORD    dwReserved;
    LPCTSTR  lpszHostName;
    LPCTSTR  lpszUserName;
    LPCTSTR  lpszPassword;
    LPCTSTR  lpszCertStore;
    LPCTSTR  lpszCertName;
    LPCTSTR  lpszKeyFile;
} SECURITYCREDENTIALS, *LPSECURITYCREDENTIALS;
```

Members

dwSize

Size of this structure. If the structure is being allocated dynamically, this member must be set to the size of the structure and all other unused structure members must be initialized to a value of zero or NULL.

dwProtocol

A bitmask of supported security protocols. The value of this structure member is constructed by using a bitwise operator with any of the following values:

Value	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_TLS	Either the TLS 1.2 or 1.3 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers which reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing

	a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Value	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

dwReserved

This structure member is reserved for future use and should always be initialized to zero.

lpszHostName

A null-terminated string which specifies the hostname that will be used when validating the server certificate. If this member is NULL, then the server certificate will be validated against the hostname used to establish the connection.

lpszUserName

A null-terminated string which identifies the owner of client certificate. Currently this member is not used by the library and should always be initialized as a NULL pointer.

lpszPassword

A null-terminated string which specifies the password needed to access the certificate. Currently this member is only used if the CREDENTIAL_STORE_FILENAME option has been specified. If there is no password associated with the certificate, then this member should be initialized as a NULL pointer.

lpszCertStore

A null-terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A null-terminated string which specifies the name of the certificate to use. The library will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the library will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the library will return an error indicating that the certificate could not be found. If the SECURITY_PROTOCOL_SSH protocol has been specified, this member should be NULL.

lpszKeyFile

This member is not used and should always be NULL. The private key cannot be specified separately and must be associated with the certificate.

Remarks

An application only needs to create this structure if the server requires the client to provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is

specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The ***dwOptions*** member should be set to CREDENTIAL_STORE_FILENAME and the ***lpszCertStore*** member should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS #12. These certificate files typically have an extension of .pfx or .p12. Note that if a password was specified when the certificate file was created, it must be provided in the ***lpszPassword*** member or the library will be unable to access the certificate.

Note that the ***lpszUserName*** and ***lpszPassword*** members are values which are used to access the certificate store or private key file. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SECURITYINFO

The **SECURITYINFO** structure contains security related information about the connection, including the protocol, cipher suite and certificate.

```
typedef struct _SECURITYINFO
{
   DWORD        dwSize;
   DWORD        dwProtocol;
   DWORD        dwCipher;
   DWORD        dwCipherStrength;
   DWORD        dwHash;
   DWORD        dwHashStrength;
   DWORD        dwKeyExchange;
   DWORD        dwCertStatus;
   SYSTEMTIME   stCertIssued;
   SYSTEMTIME   stCertExpires;
   LPCTSTR      lpszCertIssuer;
   LPCTSTR      lpszCertSubject;
   LPCTSTR      lpszFingerprint;
} SECURITYINFO, *LPSECURITYINFO;
```

Members

dwSize

Specifies the size of the data structure. This member must always be initialized to the size of the structure in bytes prior to passing the address of this structure to the function. If this this member is not initialized, an error will be returned indicating that an invalid parameter has been passed to the function.

dwProtocol

A numeric value which specifies the security protocol selected when establishing the connection.

Value	Description
SECURITY_PROTOCOL_NONE	The connection is not secure. This value indicates a standard connection was established and all other structure members will have a value of zero.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol was selected when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol was selected when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.

SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol was selected when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol was selected when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwCipher

A numeric value which specifies the cipher that was selected when establishing the secure connection.

Value	Description
SECURITY_CIPHER_AES	The Advanced Encryption Standard cipher is a fixed block size cipher which use a key size of 128, 192 or 256 bits.
SECURITY_CIPHER_DES	The Data Encryption Standard block cipher was selected. This is a fixed key length cipher, using 56-bit keys.
SECURITY_CIPHER_DES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively providing a 168-bit length key.
SECURITY_CIPHER_DESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.
SECURITY_CIPHER_RC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40 and 128 bits, in 8-bit increments.
SECURITY_CIPHER_RC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.

dwCipherStrength

A numeric value which specifies the strength (the length of the cipher key in bits) of the cipher that was selected. Typically this value will be 128 or 256. 40-bit and 56-bit key lengths are considered weak encryption, and subject to brute force attacks. 128-bit and 256-bit key lengths are considered to be secure, and are the recommended key length for secure communications.

dwHash

A numeric value which specifies the hash algorithm which was selected.

Value	Description
SECURITY_HASH_MD5	The MD5 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA1	The SHA-1 algorithm was selected. Its use has been deprecated and is no longer considered to be

	cryptographically secure.
SECURITY_HASH_SHA256	The SHA-256 algorithm was selected.
SECURITY_HASH_SHA384	The SHA-384 algorithm was selected.
SECURITY_HASH_SHA512	The SHA-512 algorithm was selected.

dwHashStrength

A numeric value which specifies the strength (the length in bits) of the message digest that was selected.

dwKeyExchange

A numeric value which specifies the key exchange algorithm which was selected.

Value	Description
SECURITY_KEYEX_RSA	The RSA public key algorithm was selected.
SECURITY_KEYEX_KEA	The Key Exchange Algorithm (KEA) was selected. This is an improved version of the Diffie-Hellman public key algorithm.
SECURITY_KEYEX_DH	The Diffie-Hellman key exchange algorithm was selected.
SECURITY_KEYEX_ECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography.

dwCertStatus

A numeric value which specifies the status of the certificate returned by the secure server.

Value	Description
SECURITY_CERTIFICATE_VALID	The certificate is valid.
SECURITY_CERTIFICATE_NOMATCH	The certificate is valid, but the domain name does not match the common name in the certificate.
SECURITY_CERTIFICATE_EXPIRED	The certificate is valid, but has expired.
SECURITY_CERTIFICATE_REVOKED	The certificate has been revoked and is no longer valid.
SECURITY_CERTIFICATE_UNTRUSTED	The certificate or certificate authority is not trusted on the local system.
SECURITY_CERTIFICATE_INVALID	The certificate is invalid. This typically indicates that the internal structure of the certificate has been damaged.

stCertIssued

A structure which contains the date and time that the certificate was issued by the certificate authority. If the issue date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values.

stCertExpires

A structure which contains the date and time that the certificate expires. If the expiration date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values.

lpszCertIssuer

A null-terminated string which contains information about the organization that issued the certificate. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate issuer could not be determined, this member may be NULL.

lpszCertSubject

A null-terminated string which contains information about the organization that the certificate was issued to. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate subject could not be determined, this member may be NULL.

lpszFingerprint

A null-terminated string which contains a sequence of hexadecimal values that uniquely identify the server. This member may be NULL.

Remarks

The size of this structure is typically determined using the **sizeof** operator in C/C++ and most other languages have a similar method for obtaining the size of a data structure or user-defined type. It is important to note the size of this structure will be different on 32-bit and 64-bit platforms due to the difference in the length of the structure members which are pointers.

When evaluating structure members which are string pointers, such as ***lpszCertIssuer*** and ***lpszCertSubject***, you should always check to ensure their values are not NULL (zero) before attempting to dereference them. If those values are undefined, it is not guaranteed they will point to zero-length strings.

There are additional protocols and ciphers defined which are not listed above because they are considered insecure and are no longer supported. It is important to note that most servers will reject attempts to use unsupported protocols such as SSL 3.0 and will either abort the connection or issue an error message and then immediately disconnect.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

SYSTEMTIME

The **SYSTEMTIME** structure represents a date and time using individual members for the month, day, year, weekday, hour, minute, second, and millisecond.

```
typedef struct _SYSTEMTIME
{
    WORD wYear;
    WORD wMonth;
    WORD wDayOfWeek;
    WORD wDay;
    WORD wHour;
    WORD wMinute;
    WORD wSecond;
    WORD wMilliseconds;
} SYSTEMTIME, *LPSYSTEMTIME;
```

Members

wYear

Specifies the current year. The year value must be greater than 1601.

wMonth

Specifies the current month. January is 1, February is 2 and so on.

wDayOfWeek

Specifies the current day of the week. Sunday is 0, Monday is 1 and so on.

wDay

Specifies the current day of the month

wHour

Specifies the current hour.

wMinute

Specifies the current minute

wSecond

Specifies the current second.

wMilliseconds

Specifies the current millisecond.

News Feed Class Library

Retrieve and process the contents of a syndicated news feed.

Reference

- Class Methods
- Data Structures
- Error Codes

Library Information

Class Name	CNewsFeed
File Name	CSRSSV12.DLL
Version	12.0.3024.1286
LibID	B8830D80-2618-4202-9C9C-9C3AD511E9D0
Import Library	CSRSSV12.LIB
Dependencies	None

Overview

Really Simple Syndication (RSS) is a collection of standardized formats that are used to publish information about content that is frequently changed. A news feed is published in XML format, which contains one or more items that includes summary text, hyperlinks to source content and additional metadata that is used to describe the item. News feeds can be used for a variety of purposes, including providing updates for weblogs, news headlines, video and audio content. RSS can also be used for other purposes, such as a software updates, where new updates are listed as items in the feed.

News feeds can be accessed remotely from a web server, or locally as an XML formatted text file. The source of the feed is determined by the URI scheme that is specified. If the http or https scheme is specified, then the feed is retrieved from a web server. If the file scheme is used, the feed is considered to be local and is accessed from the disk or local network. The CNewsFeed class provides an interface that enables you to open a feed by URL and iterate through each of the items in the feed or search for a specific feed item. The class also provides a method that can be used to parse a string that contains XML data in RSS format, where the feed may have been retrieved from other sources such as a database.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). You should install all updates for your development tools and have the current Windows SDK installed. The minimum supported version of Visual Studio is Visual Studio 2010 with Service Pack 1 (SP1) installed. The SocketTools header files are designed to be compatible with all modern C/C++ compilers and we also provide function definitions for several additional languages such as Object Pascal and Visual Basic.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are deploying applications to Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. If you are deploying applications to Windows 8, you must

have the 8.1 update installed. If you are targeting the Windows on ARM platform, the minimum required version is Windows 10 build 1709.

SocketTools includes support for both 64-bit and 32-bit Windows platforms. All current versions of Windows are 64-bit, and we include 32-bit x86 libraries to maintain compatibility with legacy development tools. SocketTools also provides native ARM64 libraries for systems running Windows on ARM. Note that 32-bit applications on ARM use x86 emulation, and Microsoft no longer supports native 32-bit ARM (ARM32) applications. Embarcadero's C++Builder and Delphi compilers (as of version 12.3) do not support building native ARM64 applications for Windows. For developing applications targeting the Windows on ARM platform, we recommend using Visual Studio 2019 or later.

The import libraries included with SocketTools are provided in several different formats. The most commonly used format is COFF, which is available for x64, x86 and native ARM64 platforms. For compatibility with older Borland (Embarcadero) compilers, we also provide OMF libraries for x86 platforms and ELF libraries for x64 platforms. If you are using Visual Studio, you will want to use the standard COFF import libraries. Note that some languages may not require import libraries and will link to the exported functions in the DLL based on the function declaration itself.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

News Feed Class Methods

Class	Description
CNewsFeed	Constructor which initializes the current instance of the class
~CNewsFeed	Destructor which releases resources allocated by the class
Method	Description
AttachHandle	Attach the specified client handle to this instance of the class
CloseFeed	Close the specified news feed and release memory allocated for the channel
DetachHandle	Detach the handle for the current instance of this class
DisableTrace	Disable logging of network function calls
EnableTrace	Enable logging of network function calls to a text file
FindItem	Find a specific news feed item using its unique identifier (GUID) property
GetErrorString	Return a description for the specified error code
GetFirstItem	Return information about the first item in the news feed channel
GetHandle	Return the client handle used by this instance of the class
GetItem	Return information about the specified news feed item
GetItemCount	Return the number of news feed items in the channel
GetItemProperty	Return the value of the specified news feed item property or attribute
GetItemText	Return the text description of the specified news feed item
GetLastError	Return the last error code
GetNextItem	Return information about the next item in the news feed channel
IsInitialized	Determine if the class has been successfully initialized
OpenFeed	Open the specified news feed and return information about the channel
ParseFeed	Parse the contents of a string and return information about the channel
RefreshFeed	Refresh the specified news feed, updating the items in the channel
SetLastError	Set the last error code
ShowError	Display a message box with a description of the specified error
StoreFeed	Store the contents of the specified news feed in an XML formatted text file
ValidateFeed	Validate the contents of the specified news feed, returning the number of items in the feed

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNewsFeed::CNewsFeed Method

```
CNewsFeed();
```

The **CNewsFeed** constructor initializes the class library and validates the license key at runtime.

Remarks

If the constructor fails to validate the runtime license, subsequent methods in this class will fail. If the product is installed with an evaluation license, then the application will only function on the development system and cannot be redistributed.

The constructor calls the **RssInitialize** function to initialize the library, which dynamically loads other system libraries and allocates thread local storage. If you are using this class within another DLL, it is important that you do not create or destroy an instance of the class from within the **DllMain** function because it can result in deadlocks or access violation errors. You should not declare static or global instances of this class within another DLL if it is linked with the C runtime library (CRT) because it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrssv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

~CNewsFeed, IsInitialized

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNewsFeed::~CNewsFeed

```
~CNewsFeed();
```

The **CNewsFeed** destructor releases resources allocated by the current instance of the **CNewsFeed** object. It also uninitializes the library if there are no other concurrent uses of the class.

Remarks

When a **CNewsFeed** object goes out of scope, the destructor is automatically called to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all handles that were created for the client session are destroyed.

The destructor is not called explicitly by the application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrssv12.lib

CNewsFeed

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNewsFeed::AttachHandle Method

```
VOID AttachHandle(
   HCHANNEL hChannel
);
```

The **AttachHandle** method attaches the specified handle to the current instance of the class.

Parameters

hChannel

The handle to the channel that will be attached to the current instance of the class object.

Return Value

None.

Remarks

This method is used to attach a handle created outside of the class using the SocketTools API. Once the handle is attached to the class, the other class member functions may be used with that news feed channel.

If a handle has already been created for the class, that handle will be released when the new handle is attached to the class object. If you want to prevent the previous news feed channel from being closed, you must call the **DetachHandle** method. Failure to close the detached handle may result in a resource leak in your application.

Note that the ***hChannel*** parameter is presumed to be valid and no checks are performed to ensure its validity. Specifying an invalid handle value will cause subsequent method calls to fail.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrssv12.lib

See Also

DetachHandle, GetHandle

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNewsFeed::CloseFeed Method

```
BOOL CloseFeed();
```

The **CloseFeed** method closes the specified news feed and releases memory allocated for the channel.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **CloseFeed** method must be called whenever the application has completed processing the news feed. It is important to note that the memory allocated for the channel will be released when this function is called, which means that any data referenced in the RSSCHANNEL and RSSCHANNELITEM structures will no longer be valid and must not be used by the application after the feed has been closed.

This method can fail if the feed is currently being updated, such as when the **RefreshFeed** method is called. In this case, the channel handle will not be released and the application must attempt to close the feed at a later time.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrssv12.lib

See Also

OpenFeed ParseFeed StoreFeed

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNewsFeed::DetachHandle Method

```
HCHANNEL DetachHandle();
```

The **DetachHandle** method detaches the handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the handle associated with the current instance of the class object. If there is no open news feed, the value INVALID_CHANNEL will be returned.

Remarks

This method is used to detach a handle created by the class for use with the SocketTools API. Once the handle is detached from the class, no other class member functions may be called. Note that the handle must be explicitly closed at some later point by the process or a resource leak will occur.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrssv12.lib

See Also

AttachHandle, GetHandle

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNewsFeed::DisableTrace Method

```
BOOL DisableTrace();
```

The **DisableTrace** method disables the logging of network function calls.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, a value of zero is returned.

Remarks

This method will disable output to the log file for the current thread or process, depending on the flags used when logging was enabled. If this method is not called, the resources that were allocated for the logging session will be released when the process ends.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrssv12.lib

See Also

EnableTrace

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNewsFeed::EnableTrace Method

```
BOOL EnableTrace(
   LPCTSTR lpszTraceFile,
   DWORD dwTraceFlags
);
```

The **EnableTrace** method enables the logging of network function calls to a file.

Parameters

lpszTraceFile

A null-terminated string which specifies the name of the logfile which will be appended to or created. It is recommended that this file always specify an absolute path to avoid any ambiguity. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
TRACE_INFO	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
TRACE_ERROR	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
TRACE_HEXDUMP	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
TRACE_TRUNCATE	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for

	multithreaded applications that are using worker threads.

Return Value

If the method succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the log file cannot be created.

Remarks

Logging is enabled and disabled at the thread or process level, depending on the flags passed to this method, and is not associated with a specific class instance. When logging is enabled, the information is appended to the specified file. If the file does not exist, it will be created. To limit the size of the file, enable and disable logging only around those sections of code that you wish to debug. If you do not provide a full path to the file, it will be relative to the current working directory for the process. This can produce unexpected results in multithreaded applications because the current directory is global to the entire process and can be changed by any thread at any time.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

The TRACE_HEXDUMP option can generate very large files because it includes all of the data exchanged between your application and the remote host. The TRACE_TRUNCATE option is only evaluated when logging is first enabled for a thread or process. If logging is already active, specifying this option will have no effect.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "**0x**". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxxx:xxxx::xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, a connection is being made to a system with the IPv4 address 192.0.0.1 on port 1234.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrssv12.lib
Unicode: Implemented as Unicode and ANSI versions

CNewsFeed::FindItem Method

```
BOOL FindItem(
   LPCTSTR lpszValue,
   DWORD dwOptions,
   LPRSSCHANNELITEM lpItem
);

BOOL FindItem(
   LPCTSTR lpszValue,
   LPRSSCHANNELITEM lpItem
);
```

The **FindItem** method searches for an item in the news feed channel which matches the unique identifier (GUID) value and returns information about that item.

Parameters

lpszValue

A null-terminated string which specifies the value of the item being searched for. This value should uniquely identify the item in the feed, and this parameter cannot be an empty string or NULL pointer.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
RSS_FIND_GUID	Search the feed for items with a matching GUID property value. This is the default option, and is the only item property that is guaranteed to be unique in the feed. The search is case-sensitive, requiring that the ***lpszValue*** parameter match the property value exactly.
RSS_FIND_LINK	Search the feed for items with a matching link property value. For feeds that do not specify a GUID property, this is the recommended option for searching for an item. The search is not case-sensitive.
RSS_FIND_TITLE	Search the feed for items with a matching title. This option should not be used if you must ensure that the item returned is unique in the feed because there may be multiple items with the same title in the feed. The search is not case-sensitive.
RSS_FIND_PUBDATE	Search the feed for items with a matching publishing date. This option should not be used if you must ensure that the item returned is unique in the feed because more than one item may have the same publishing date. The format of the date string must match the standard format used with the RSS protocol and the match is not case-sensitive.

lpItem

A pointer to a **RSSCHANNELITEM** structure which contains information about the specified item in the news feed. This structure is initialized by the method and the parameter can never be specified as a NULL pointer.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

It is recommended that you use the RSS_FIND_GUID option with news feeds that are using version 2.0 or later of the RSS specification. If the feed uses an earlier version, items may not include a GUID property. It is also possible that a feed may omit the GUID property even though it is considered a requirement for the current RSS specification. For the broadest compatibility with all news feeds, an application should not depend on being able to search for a specific news feed item by its GUID.

Only the GUID property is guaranteed to be unique in the feed. If the feed does not specify GUIDs for the news items, the application must use an alternate criteria such as the item hyperlink or publishing date. If there are multiple items that match the ***lpszValue*** value, the first matching item will be returned.

The data referenced in the **RSSCHANNELITEM** structure should be considered read-only and never modified by the application. Not all members of the structure may contain valid values, in which case those members will either have a value of zero or will specify NULL pointers. When the feed is closed, the members of this structure will no longer be valid, and therefore should never be stored by the application. If the application needs to store or modify this information, it should create its own private copy of the data.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrssv12.lib
Unicode: Implemented as Unicode and ANSI versions

CNewsFeed::GetErrorString Method

```
INT GetErrorString(
   DWORD dwErrorCode,
   LPTSTR lpszDescription,
   INT nMaxLength
);

INT GetErrorString(
   DWORD dwErrorCode,
   CString& strDescription
);
```

The **GetErrorString** method is used to return a description of a specific error code. Typically this is used in conjunction with the **GetLastError** method for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

The buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length. An alternate form of the method accepts a **CString** variable which will contain the error description.

nMaxLength

The maximum number of characters that may be copied into the description buffer.

Return Value

If the method succeeds, the return value is the length of the description string. If the method fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the method is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrssv12.lib
Unicode: Implemented as Unicode and ANSI versions

CNewsFeed::GetFirstItem Method

```
BOOL GetFirstItem(
   LPRSSCHANNELITEM lpItem
);
```

The **GetFirstItem** method returns information about the first item in the news feed channel.

Parameters

lpItem

A pointer to a **RSSCHANNELITEM** structure which contains information about the first item in the news feed. This structure is initialized by the method and the parameter can never be specified as a NULL pointer.

Return Value

If the method succeeds, it returns a non-zero value. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetFirstItem** method is used in conjunction with the **GetNextItem** method to enumerate the available items in the specified news feed channel. If this method fails, it typically indicates that the channel does not contain any valid news items or that the format of the news feed is invalid.

The data referenced in the **RSSCHANNELITEM** structure should be considered read-only and never modified by the application. Not all members of the structure may contain valid values, in which case those members will either have a value of zero or will specify NULL pointers. When the feed is closed, the members of this structure will no longer be valid, and therefore should never be stored by the application. If the application needs to store or modify this information, it should create its own private copy of the data.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrssv12.lib
Unicode: Implemented as Unicode and ANSI versions

CNewsFeed::GetHandle Method

```
HCHANNEL GetHandle();
```

The **GetHandle** method returns the handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the handle associated with the current instance of the class object. If there is no open news feed, the value INVALID_CHANNEL will be returned.

Remarks

This method is used to obtain the handle created by the class for use with the SocketTools API.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrssv12.lib

CNewsFeed::GetItem Method

```
BOOL GetItem(
   UINT nItemId,
   LPRSSCHANNELITEM lpItem
);
```

The **GetItem** method returns information about the specified item in the news feed channel.

Parameters

nItemId

An integer value which identifies the news feed item. The first item identifier in the news feed has a value of one, and that value is incremented for each additional item in the feed. If this parameter is zero or specifies a value larger than the number of items in the feed, this method will fail.

lpItem

A pointer to a **RSSCHANNELITEM** structure which contains information about the specified item in the news feed. This structure is initialized by the method and the parameter can never be specified as a NULL pointer.

Return Value

If the method succeeds, it returns a non-zero value. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetItem** method is used to return information about a specific item in the news feed. If this method fails, it typically indicates that the item ID is invalid or that the feed does not contain any valid news items. The **GetItemCount** method can be used to determine the number of items contained in the feed channel.

The data referenced in the **RSSCHANNELITEM** structure should be considered read-only and never modified by the application. Not all members of the structure may contain valid values, in which case those members will either have a value of zero or will specify NULL pointers. When the feed is closed, the members of this structure will no longer be valid, and therefore should never be stored by the application. If the application needs to store or modify this information, it should create its own private copy of the data.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrssv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

FindItem, GetFirstItem, GetItemCount, GetItemProperty, GetItemText, GetNextItem, RSSCHANNELITEM

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNewsFeed::GetItemCount Method

```
INT GetItemCount();
```

The **GetItemCount** method returns the number of items in the news feed channel.

Parameters

None.

Return Value

If the method succeeds, the return value is the number of items in the news feed. A value of zero indicates that the feed channel is empty. If the method fails, the return value is RSS_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetItemCount** method is used to determine the number of items that are contained in the news feed channel, and therefore determine the maximum value of the item identifier which can be used to reference a specific item in the feed. This value is the same as the value specified by the *nItemCount* member of the **RSSCHANNEL** structure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrssv12.lib

See Also

FindItem, GetItem, GetItemProperty, GetItemText, RSSCHANNEL

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNewsFeed::GetItemProperty Method

```
INT GetItemProperty(
   UINT nItemId,
   LPCTSTR lpszProperty,
   LPCTSTR lpszAttribute,
   LPTSTR lpszValue,
   INT nMaxLength
);

INT GetItemProperty(
   UINT nItemId,
   LPCTSTR lpszProperty,
   LPCTSTR lpszAttribute,
   CString& strValue
);
```

The **GetItemProperty** method is used to return the value of a property for the specified item in the news feed channel.

Parameters

nItemId

An integer value which identifies the news feed item. The first item identifier in the news feed has a value of one, and that value is incremented for each additional item in the feed. If this parameter is zero or specifies a value larger than the number of items in the feed, this method will fail.

lpszProperty

A null-terminated string which specifies the name of the item property. This parameter cannot point to an empty string or specify a NULL pointer.

lpszAttribute

A null-terminated string which specifies the name of an attribute for the property. If this parameter is an empty string or NULL pointer, the method will return the value of the property, rather than an attribute of the specified property.

lpszValue

A null-terminated string buffer which will contain the value of the specified item property or attribute. This string should be large enough to contain the property value. If this parameter is a NULL pointer, it will be ignored and the method will only return the length of value for the specified property.

nMaxLength

The maximum number of characters that may be copied into the property value buffer. If the value of this parameter is zero, then the ***lpszValue*** parameter is ignored and the method will only return the length of the value for the specified property.

Return Value

If the method succeeds, the return value is the length of the property value string. A return value of zero indicates that the property does not contain any value. If the method fails, the return value is RSS_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetItemProperty** method is primarily used with custom item properties that may be used with

extensions to the news feed. The standard properties for an item such as the title, link and description can be obtained using **GetItem** and related methods. However, if items in the feed contain custom properties that are not part of the standard RSS format, this method can be used to obtain those values.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrssv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

FindItem, GetItem, GetItemText, RSSCHANNELITEM

CNewsFeed::GetItemText Method

```
INT GetItemText(
   UINT nItemId,
   LPTSTR lpszBuffer,
   INT nMaxLength
);

INT GetItemText(
   UINT nItemId,
   CString& strBuffer
);
```

The **GetItemText** method is used to return a copy of an item's description.

Parameters

nItemId

An integer value which identifies the news feed item. The first item identifier in the news feed has a value of one, and that value is incremented for each additional item in the feed. If this parameter is zero or specifies a value larger than the number of items in the feed, this method will fail.

lpszBuffer

A null-terminated string buffer which will contain the value of the item description. If this parameter is a NULL pointer, it will be ignored and the method will only return the length of the item description.

nMaxLength

The maximum number of characters that may be copied into the description buffer. If the value of this parameter is zero, then the ***lpszValue*** parameter is ignored and the method will only return the length of the item description.

Return Value

If the method succeeds, the return value is the length of the item description. A return value of zero indicates that the item does not have a description. If the method fails, the return value is RSS_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetItemText** function is used to obtain a copy of the string that describes the specified item. Typically this is text that provides a summary of the news feed item and is used in conjunction with the item's title and hyperlink to additional content.

The content of an item description is typically either plain text or HTML formatted text. It is the responsibility of the application to display the content in a format is appropriate for the end-user.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrssv12.lib
Unicode: Implemented as Unicode and ANSI versions

CNewsFeed::GetLastError Method

```
DWORD GetLastError();

DWORD GetLastError(
   CString& strDescription
);
```

Parameters

strDescription

A string which will contain a description of the last error code value when the method returns. If no error has been set, or the last error code has been cleared, this string will be empty.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **SetLastError** method. The Return Value section of each reference page notes the conditions under which the method sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **GetLastError** method immediately when a method's return value indicates that an error has occurred. That is because some methods call **SetLastError**(0) when they succeed, clearing the error code set by the most recently failed method.

Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or RSS_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

The description of the error code is the same string that is returned by the **GetErrorString** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrssv12.lib

See Also

GetErrorString, SetLastError, ShowError

CNewsFeed::GetNextItem Method

```
BOOL GetNextItem(
   LPRSSCHANNELITEM lpItem
);
```

The **GetNextItem** method returns information about the next item in the news feed channel.

Parameters

lpItem

A pointer to a **RSSCHANNELITEM** structure which contains information about the next item in the news feed. This structure is initialized by the method and the parameter can never be specified as a NULL pointer.

Return Value

If the method succeeds, it returns a non-zero value. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetNextItem** method is used in conjunction with the **GetFirstItem** method to enumerate the available items in the specified news feed channel. If this method fails, it typically indicates that there are no more items in the news feed channel.

The data referenced in the **RSSCHANNELITEM** structure should be considered read-only and never modified by the application. Not all members of the structure may contain valid values, in which case those members will either have a value of zero or will specify NULL pointers. When the feed is closed, the members of this structure will no longer be valid, and therefore should never be stored by the application. If the application needs to store or modify this information, it should create its own private copy of the data.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrssv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

FindItem, GetFirstItem, GetItem, GetItemProperty, GetItemText, RSSCHANNELITEM

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNewsFeed::IsInitialized Method

```
BOOL IsInitialized();
```

The **IsInitialized** method returns whether or not the class object has been successfully initialized.

Parameters

None.

Return Value

This method returns a non-zero value if the class object has been successfully initialized. A return value of zero indicates that the runtime license key could not be validated or the networking library could not be loaded by the current process.

Remarks

When an instance of the class is created, the class constructor will attempt to initialize the component with the runtime license key that was created when SocketTools was installed. If the constructor is unable to validate the license key or load the networking libraries, this initialization will fail.

If SocketTools was installed with an evaluation license, the application cannot be redistributed to another system. The class object will fail to initialize if the application is executed on another system, or if the evaluation period has expired. To redistribute your application, you must purchase a development license which will include the runtime key that is needed to redistribute your software to other systems. Refer to the Developer's Guide for more information.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrssv12.lib

See Also

CNewsFeed

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNewsFeed::OpenFeed Method

```
BOOL OpenFeed(
   LPCTSTR lpszFeedUrl,
   UINT nTimeout,
   DWORD dwOptions,
   LPRSSCHANNEL lpChannel
);

BOOL OpenFeed(
   LPCTSTR lpszFeedUrl,
   UINT nTimeout,
   LPRSSCHANNEL lpChannel
);

BOOL OpenFeed(
   LPCTSTR lpszFeedUrl,
   LPRSSCHANNEL lpChannel
);
```

The **OpenFeed** method is used to open a news feed and return a handle which can be used to access the individual news items in the feed.

Parameters

lpszFeedUrl

A null-terminated string which specifies the URL for the news feed. To access a news feed on a web server, a standard http or https URL may be specified. To access a file on the local system or network share, a file name or file URL may be specified.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation. This parameter is ignored if the *lpszFeedUrl* parameter specifies a local file name or URL.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
RSS_OPTION_NONE	No additional options are specified and the news feed is processed using relaxed rules when checking the validity of the feed. The library will attempt to automatically compensate for a feed that is malformed or does not strictly conform to the RSS standard.
RSS_OPTION_STRICT	The news feed content should be processed using strict rules to ensure that the feed meets the appropriate RSS standard specification and all feed property values are case-sensitive. By default, relaxed rules are used which allows the application to open a feed that may not strictly conform to the standard specification.

lpChannel

A pointer to an **RSSCHANNEL** structure which contains information about the news feed channel such as the feed title, hyperlink and description. If the parameter is not NULL, the structure is initialized by the method. If the parameter is NULL, it is ignored and no information is returned.

Return Value

If the method succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

A news feed may be local or remote, depending on the URL that is specified. If a local file name or file URL is specified for the feed, then it is opened locally and no network access is required. If an http or https URL is specified, then **OpenFeed** will attempt to download the feed from the server and store it temporarily on the local system. Accessing a remote feed requires that the application has permission to establish a connection with the server and will cause the application to block until the feed has been downloaded, the operation times out or an error occurs.

Although the **OpenFeed** method will meet the needs of most applications, if you require more complex functionality such as retrieving the feed asynchronously in the background or event notifications for large transfers, you can use the SocketTools Hypertext Transfer Protocol API to download the news feed and then use the **ParseFeed** method to parse the contents.

The data referenced in the **RSSCHANNEL** structure should be considered read-only and never modified by the application. Not all members of the structure may contain valid values, in which case those members will either have a value of zero or will specify NULL pointers. When the feed is closed, the members of this structure will no longer be valid, and therefore should never be stored by the application. If the application needs to store or modify this information, it should create its own private copy of the data.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrssv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CloseFeed, ParseFeed, RefreshFeed, StoreFeed, RSSCHANNEL

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNewsFeed::ParseFeed Method

```
BOOL ParseFeed(
   LPCTSTR lpszFeedXml,
   DWORD dwOptions,
   LPRSSCHANNEL lpChannel
);

BOOL ParseFeed(
   LPCTSTR lpszFeedXml,
   LPRSSCHANNEL lpChannel
);
```

The **ParseFeed** method is used to parse the contents of a news feed, returning a handle which can be used to access the individual news items in the feed.

Parameters

lpszFeedXml

A null-terminated string which contains the contents of the news feed. The string must contain XML formatted data that conforms to the RSS standard specification. This parameter cannot specify an empty string or a NULL pointer.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
RSS_OPTION_NONE	No additional options are specified.
RSS_OPTION_STRICT	The news feed content should be processed using strict rules to ensure that the feed meets the appropriate RSS standard specification and all feed property values are case-sensitive. By default, relaxed rules are used which allows the application to open a feed that may not strictly conform to the standard specification.

lpChannel

A pointer to an **RSSCHANNEL** structure which contains information about the news feed channel such as the feed title, hyperlink and description. If the parameter is not NULL, the structure is initialized by the method. If the parameter is NULL, it is ignored and no information is returned.

Return Value

If the method succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **ParseFeed** method is an alternative to the **OpenFeed** method, enabling the application to process a news feed from alternative sources such as a database or compressed file. It is important to note that the string which contains the news feed XML must be properly formatted and conform to the RSS standard specification.

The data referenced in the **RSSCHANNEL** structure should be considered read-only and never modified by the application. Not all members of the structure may contain valid values, in which case those members will either have a value of zero or will specify NULL pointers. When the feed is closed,

the members of this structure will no longer be valid, and therefore should never be stored by the application. If the application needs to store or modify this information, it should create its own private copy of the data.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrssv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CloseFeed, OpenFeed, RefreshFeed, StoreFeed, RSSCHANNEL

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNewsFeed::RefreshFeed Method

```
BOOL RefreshFeed(
   LPRSSCHANNEL lpChannel
);
```

The **RefreshFeed** method reloads the news feed and updates the items in the channel.

Parameters

lpChannel

A pointer to an **RSSCHANNEL** structure which contains information about the news feed channel such as the feed title, hyperlink and description. If the parameter is not NULL, the structure is initialized by the method. If the parameter is NULL, it is ignored and no information is returned.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

When the **RefreshFeed** method is called, the news feed is reloaded from the original source and the items in the channel are updated. For news feeds that are frequently updated, the *nTimeToLive* member of the **RSSCHANNEL** structure can provide a hint to the application as to how frequently the feed should be refreshed.

If the news feed was originally opened using an http or https URL, this method will download the updated feed from the server and store it temporarily on the local system. Accessing a remote feed requires that the application has permission to establish a connection with the server and will cause the application to block until the feed has been downloaded, the operation times out or an error occurs. The same timeout period and options will be used as when the feed was originally opened.

The **RefreshFeed** method should only be used if the feed was opened using the **OpenFeed** method, otherwise the method will fail with an error indicating that the operation is not supported.

The data referenced in the **RSSCHANNEL** structure should be considered read-only and never modified by the application. The members of this structure returned by previous calls to either the **OpenFeed** or **RefreshFeed** methods will no longer be valid and should not be referenced. Likewise, the members of an **RSSCHANNELITEM** structure will no longer be valid after this method returns.

It is important that the application does not make any assumptions about the number of news items in the channel, or the content associated with those items after the **RefreshFeed** function has been called. For example, never assume that the number of items in the channel remains the same, or that the item IDs for each item remains the same. If you need to find a specific item in the news feed, use the **FindItem** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrssv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CNewsFeed::SetLastError Method

```
VOID SetLastError(
   DWORD dwErrorCode
);
```

The **SetLastError** method sets the last error code for the current thread. This method is typically used to clear the last error by specifying a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or RSS_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

Applications can retrieve the value saved by this method by using the **GetLastError** method. The use of **GetLastError** is optional; an application can call the method to determine the specific reason for a method failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrssv12.lib

See Also

GetErrorString, GetLastError, ShowError

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CNewsFeed::ShowError Method

```
INT ShowError(
   LPCTSTR lpszAppTitle,
   UINT uType,
   DWORD dwErrorCode
);
```

The **ShowError** method displays a message box which describes the specified error.

Parameters

lpszAppTitle

A null-terminated string which specifies the title of the message box that is displayed. If this argument is NULL or omitted, then the default title of "Error" will be displayed.

uType

An unsigned integer which specifies the type of message box that will be displayed. This is the same value that is used by the **MessageBox** method in the Windows API. If a value of zero is specified, then a message box with a single OK button will be displayed. Refer to that method for a complete list of options.

dwErrorCode

Specifies the error code that will be used when displaying the message box. If this argument is zero, then the last error that occurred in the current thread will be displayed.

Return Value

If the method is successful, the return value will be the return value from the **MessageBox** function. If the method fails, it will return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrssv12.lib
Unicode: Implemented as Unicode and ANSI versions

CNewsFeed::StoreFeed Method

```
BOOL StoreFeed(
   LPCTSTR lpszFileName
);
```

The **StoreFeed** method stores the contents of the news feed in an XML formatted text file.

Parameters

lpszFileName

A null-terminated string which specifies the name of the file on the local system. The contents of the news feed will be stored in this file. If the file does not exist, it will be created; otherwise it will overwrite the contents of the file.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrssv12.lib
Unicode: Implemented as Unicode and ANSI versions

CNewsFeed::ValidateFeed Method

```
INT ValidateFeed(
   LPCTSTR lpszFeedUrl,
   UINT nTimeout,
   DWORD dwOptions,
   LPSYSTEMTIME lpstModified
);

INT ValidateFeed(
   LPCTSTR lpszFeedUrl,
   LPSYSTEMTIME lpstModified
);

INT ValidateFeed(
   LPCTSTR lpszFeedUrl
);
```

The **RssValidateFeed** method is used to validate a news feed, returning the number of items in the feed and the date it was last modified.

Parameters

lpszFeedUrl

A null-terminated string which specifies the URL for the news feed. To access a news feed on a web server, a standard http or https URL may be specified. To access a file on the local system or network share, a file name or file URL may be specified.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation. This parameter is ignored if the *lpszFeedUrl* parameter specifies a local file name or URL.

dwOptions

An unsigned integer that specifies one or more options. This parameter is reserved for future use an should always have a value of zero.

lpstModified

A pointer to a **SYSTEMTIME** structure which will specify the date that the feed was last modified when the method returns. If the parameter is NULL, it is ignored and no information is returned.

Return Value

If the method succeeds, the return value is the number of items in the news feed channel. If the method fails, the return value is RSS_ERROR. To get extended error information, call **RssGetLastError**.

Remarks

The **RssValidateFeed** method can be used to check that a news feed exists and is properly formatted. If the contents of the feed are valid, the method will return the number of items in the feed and the date that it was last modified. This can be useful for applications that want to periodically check a news feed and determine if the contents have changed.

The **SYSTEMTIME** structure that is populated by the method specifies the date when the feed was last modified. The method first checks the value of the lastBuildDate property of the feed channel. If that property is not defined, then it will use the value of the pubDate property. If neither are defined, then the structure members will have a value of zero.

The validation process imposes strict checks on the structure of the news feed and requires that it conform to the RSS specification. For example, the feed must have a title, link and description. Each item in the feed must have either a title or description, and the hyperlinks specified in the feed must be valid. If the feed XML is malformed, or a required property of the feed is invalid or missing, this method will fail.

If a news feed cannot be validated, it still may be possible to open the feed using the **OpenFeed** method. By default, relaxed rules are used when parsing the contents of the feed and it does not check to ensure all required properties are defined and have valid values.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrssv12.lib
Unicode: Implemented as Unicode and ANSI versions

- RSSCHANNELITEM
- SYSTEMTIME

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

RSSCHANNEL

The **RSSCHANNEL** structure contains information about the properties of the news feed channel.

```
typedef struct _RSSCHANNEL
{
    UINT        nItemCount;
    UINT        nTimeToLive;
    WORD        wVersionMajor;
    WORD        wVersionMinor;
    DWORD       dwFlags;
    DWORD       dwReserved;
    LPCTSTR     lpszTitle;
    LPCTSTR     lpszLink;
    LPCTSTR     lpszDescription;
    LPCTSTR     lpszCategory;
    LPCTSTR     lpszLanguage;
    LPCTSTR     lpszCopyright;
    LPCTSTR     lpszEditor;
    LPCTSTR     lpszWebmaster;
    LPCTSTR     lpszGenerator;
    LPCTSTR     lpszImageLink;
    LPCTSTR     lpszImageTitle;
    LPCTSTR     lpszImageUrl;
    SYSTEMTIME  stPublished;
    SYSTEMTIME  stLastBuild;
}  RSSCHANNEL, *LPRSSCHANNEL;
```

Members

nItemCount

An integer value which specifies number of news items in the channel.

nTimeToLive

An integer value which specifies the frequency in seconds at which the feed should be refreshed to obtain updated information. Not all feeds specify a time-to-live, in which case this member will have a value of zero.

wVersionMajor

A word value which specifies the major version number for the news feed.

wVersionMinor

A word value which specifies the minor version number for the news feed.

dwFlags

A value which specifies one or more option flags for the news feed channel. Currently there are no option flags defined and this member is reserved for future expansion.

dwReserved

A value reserved for future expansion.

lpszTitle

A null-terminated string which specifies the name of the channel. If the content of the news feed corresponds to a website, this is typically the same as the title of the website. If a title has not been specified, this member will be NULL. Note that a strictly conforming news feed requires a title.

lpszLink

A null-terminated string which specifies a URL to the website corresponding to the channel. Note

that this is not the URL of the news feed itself. Typically it is a link to the home page of the site which owns the news feed. If a link has not been specified, this member will be NULL. Note that a strictly conforming news feed requires a valid link URL.

lpszDescription

A null-terminated string which describes the channel. This provides an overview of the news feed and the type of information that is provided. If a description of the feed has not been specified, this member will be NULL. Note that a strictly conforming news feed requires a description.

lpszCategory

A null-terminated string which defines the category or categories that the channel belongs to. This property is optional and the category names themselves are user-defined. If a category has not been specified, this member will be NULL.

lpszLanguage

A null-terminated string which defines the language the channel is written in, using the standard language codes. This property is optional and if this member is NULL, the English language is typically presumed to be the default.

lpszCopyright

A null-terminated string which specifies a copyright notice for the content. If a copyright has not been specified, this member will be NULL.

lpszEditor

A null-terminated string which identifies the person responsible for managing the content of the news feed. If this property is defined, it is typically the name and email address of the feed editor. If an editor has not been specified, this member will be NULL.

lpszWebmaster

A null-terminated string which identifies the person responsible for technical issues related to the news feed. If this property is defined, it is typically the name and email address of a system administrator. If a webmaster has not been specified, this member will be NULL.

lpszGenerator

A null-terminated string which identifies the application that was used to create the news feed. If the application that generated the feed has not been specified, this member will be NULL.

lpszImageLink

A null-terminated string which specifies a URL to the website corresponding to the channel. In most cases, this is the same URL that is specified by the ***lpszLink*** member. If an image link has not been specified, this member will be NULL.

lpszImageTitle

A null-terminated string which identifies the image associated with the channel. This is usually a brief description of the image, and may be the same as the value specified by the ***lpszTitle*** member. If an image title has not been specified, this member will be NULL.

lpszImageUrl

A null-terminated string which specifies a URL for the image associated with the channel. An application can download this image and display it with the contents of the news feed. If an image URL has not been specified, this member will be NULL.

stPublished

The date that the news feed was published. For example, a feed that is associated with a weekly print publication may update this value once per week. Note that this is not necessarily the date that

the feed was last modified. If the channel does not specify the publish date, this structure will contain all zeroes.

stLastBuild

The date that the content of the channel was last modified. If the channel does not specify the build date, this structure will contain all zeroes.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

RSSCHANNELITEM

The **RSSCHANNELITEM** structure contains information about the properties of an item in a news feed channel.

```
typedef struct _RSSCHANNELITEM
{
    UINT        nItemId;
    DWORD       dwFlags;
    DWORD       dwReserved;
    LPCTSTR     lpszTitle;
    LPCTSTR     lpszLink;
    LPCTSTR     lpszText;
    LPCTSTR     lpszGuid;
    LPCTSTR     lpszAuthor;
    LPCTSTR     lpszSource;
    LPCTSTR     lpszComments;
    LPCTSTR     lpszEnclosure;
    SYSTEMTIME  stPublished;
}  RSSCHANNELITEM, *LPRSSCHANNELITEM;
```

Members

nItemId

An integer which identifies this item in the channel.

dwFlags

A value which specifies one or more option flags for the item. Currently there are no option flags defined and this member is reserved for future expansion.

dwReserved

A value reserved for future expansion.

lpszTitle

A null-terminated string which specifies the title of the item. If a title for the item has not been specified, this member will be NULL.

lpszLink

A null-terminated string which specifies a URL that typically links to additional information related to the item. If a link for the item has not been specified, this member will be NULL.

lpszText

A null-terminated string which specifies a summary or description of the item. This may contain either plain text or HTML formatted text, and there is no fixed limit to the length of the text. If no text has been specified for the item, this member will be NULL.

lpszGuid

A null-terminated string which uniquely identifies the item in the channel. If this property is defined, it is guaranteed to be a unique, persistent value. It is important to note that this string does not have to be a standard GUID reference number, it can be any unique string. In many cases it is the same value as the item hyperlink specified by the ***lpszLink*** member, although an application should never depend on this behavior. If there is no unique identifier associated with the item, this member will be NULL.

lpszAuthor

A null-terminated string which identifies the author of the item. If this property is defined, it is

typically the name and email address of the person who created the content that the item links to. If the author is not specified, this member will be NULL.

lpszSource

A null-terminated string which identifies the source of the item, specified as a URL for the original news feed that contained it. This typically used to propagate credit for items that are aggregated by a third-party and re-published in their own channel. If the source is not specified, this member will be NULL.

lpszComments

A null-terminated string which specifies a URL that links to further discussion about the item. Typically this is a link to the comment area of a weblog or a forum topic specific to the item. If a comment link is not specified, this member will be NULL.

lpszEnclosure

A null-terminated string which specifies a URL that links to a file related to the item. This is similar to an attachment in an email message, however instead of the item containing the contents of the attached file, it only specifies a link to the file. Enclosures are most commonly used with podcasting where an item is linked to an audio or video file, however the link may reference any type of file. If there is no enclosure specified for the item, this member will be NULL.

stPublished

The date that the item was published. If the item does not specify the publish date, this structure will contain all zeroes.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

SYSTEMTIME

The **SYSTEMTIME** structure represents a date and time using individual members for the month, day, year, weekday, hour, minute, second, and millisecond.

```
typedef struct _SYSTEMTIME
{
    WORD wYear;
    WORD wMonth;
    WORD wDayOfWeek;
    WORD wDay;
    WORD wHour;
    WORD wMinute;
    WORD wSecond;
    WORD wMilliseconds;
} SYSTEMTIME, *LPSYSTEMTIME;
```

Members

wYear

Specifies the current year. The year value must be greater than 1601.

wMonth

Specifies the current month. January is 1, February is 2 and so on.

wDayOfWeek

Specifies the current day of the week. Sunday is 0, Monday is 1 and so on.

wDay

Specifies the current day of the month

wHour

Specifies the current hour.

wMinute

Specifies the current minute

wSecond

Specifies the current second.

wMilliseconds

Specifies the current millisecond.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Post Office Protocol Class Library

List and retrieve email messages from a mail server.

Reference

- Class Methods
- Data Structures
- Error Codes

Library Information

Class Name	CPopClient
File Name	CSPOPV12.DLL
Version	12.0.3024.1286
LibID	33EB8402-9A5F-4ADD-B520-9C24EC56F1A1
Import Library	CSPOPV12.LIB
Dependencies	None
Standards	RFC 1939

Overview

The Post Office Protocol (POP3) provides access to a user's new email messages on a mail server. Functions are provided for listing available messages and then retrieving those messages, storing them either in files or in memory. Once a user's messages have been downloaded to the local system, they are typically removed from the server. The class provides a complete interface for managing a user's mailbox and is typically used in conjunction with the CMailMessage class, which is used to parse the messages retrieved from the server.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). You should install all updates for your development tools and have the current Windows SDK installed. The minimum supported version of Visual Studio is Visual Studio 2010 with Service Pack 1 (SP1) installed. The SocketTools header files are designed to be compatible with all modern C/C++ compilers and we also provide function definitions for several additional languages such as Object Pascal and Visual Basic.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are deploying applications to Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. If you are deploying applications to Windows 8, you must have the 8.1 update installed. If you are targeting the Windows on ARM platform, the minimum required version is Windows 10 build 1709.

SocketTools includes support for both 64-bit and 32-bit Windows platforms. All current versions of Windows are 64-bit, and we include 32-bit x86 libraries to maintain compatibility with legacy development tools. SocketTools also provides native ARM64 libraries for systems running Windows on ARM. Note that 32-bit applications on ARM use x86 emulation, and Microsoft no longer supports native 32-bit ARM (ARM32) applications. Embarcadero's C++Builder and Delphi compilers (as of version 12.3) do not support building native ARM64 applications for Windows. For developing

applications targeting the Windows on ARM platform, we recommend using Visual Studio 2019 or later.

The import libraries included with SocketTools are provided in several different formats. The most commonly used format is COFF, which is available for x64, x86 and native ARM64 platforms. For compatibility with older Borland (Embarcadero) compilers, we also provide OMF libraries for x86 platforms and ELF libraries for x64 platforms. If you are using Visual Studio, you will want to use the standard COFF import libraries. Note that some languages may not require import libraries and will link to the exported functions in the DLL based on the function declaration itself.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Post Office Protocol Class Methods

Class	Description
CPopClient	Constructor which initializes the current instance of the class
~CPopClient	Destructor which releases resources allocated by the class
Method	Description
AttachHandle	Attach the specified client handle to this instance of the class
AttachThread	Attach the specified client handle to another thread
Cancel	Cancel the current blocking operation
ChangePassword	Change the specified mail account password
Command	Send a command to the server
Connect	Connect to the specified server
CreateSecurityCredentials	Allocate a structure to establish client security credentials
DeleteMessage	Delete the specified message from the mailbox
DeleteSecurityCredentials	Delete the specified client security credentials
DetachHandle	Detach the handle for the current instance of this class
DisableEvents	Disable the event notification mechanism
DisableTrace	Disable logging of network function calls
Disconnect	Disconnect from the current server
EnableEvents	Enable the client event notification mechanism
EnableTrace	Enable logging of network function calls to a file
FreezeEvents	Suspend and resume event handling by the client
GetErrorString	Return a description for the specified error code
GetHandle	Return the client handle used by this instance of the class
GetHeaderValue	Return the value of the specified header field
GetLastError	Return the last error code
GetMessage	Retrieve the specified message from the server
GetMessageCount	Return the number of messages available in the mailbox
GetMessageHeaders	Retrieve the specified message header from the server
GetMessageId	Return the message ID string for the specified message
GetMessageSender	Return the address of the message sender
GetMessageSize	Return the size of the specified message
GetMessageUID	Return the unique identifier for the specified message
GetResultCode	Return the result code from the previous command

GetResultString	Return the result string from the previous command
GetSecurityInformation	Return security information about the current client connection
GetStatus	Return the current status of the client
GetTimeout	Return the number of seconds until an operation times out
GetTransferStatus	Return data transfer statistics
IsBlocking	Determine if the client is blocked, waiting for information
IsConnected	Determine if the client is connected to the server
IsInitialized	Determine if the class has been successfully initialized
IsReadable	Determine if data can be read from the server
IsWritable	Determine if data can be written to the server
Login	Login to the server
OpenMessage	Open the specified message for reading on the server
PopEventProc	Callback method that processes events generated by the client
Read	Read data returned by the server
RegisterEvent	Register an event handler for the specified event
Reset	Reset the client and return to a command state
SendMessage	Send a message through the mail server
SetLastError	Set the last error code
SetTimeout	Set the number of seconds until an operation times out
ShowError	Display a message box with a description of the specified error
StoreMessage	Store the contents of a message in the specified file
Write	Write data to the server

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CPopClient::CPopClient Method

```
CPopClient();
```

The **CPopClient** constructor initializes the class library and validates the license key at runtime.

Remarks

If the constructor fails to validate the runtime license, subsequent methods in this class will fail. If the product is installed with an evaluation license, then the application will only function on the development system and cannot be redistributed.

The constructor calls the **PopInitialize** function to initialize the library, which dynamically loads other system libraries and allocates thread local storage. If you are using this class within another DLL, it is important that you do not create or destroy an instance of the class from within the **DllMain** function because it can result in deadlocks or access violation errors. You should not declare static or global instances of this class within another DLL if it is linked with the C runtime library (CRT) because it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

~CPopClient, IsInitialized

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CPopClient::~CPopClient

```
~CPopClient();
```

The **CPopClient** destructor releases resources allocated by the current instance of the **CPopClient** object. It also uninitializes the library if there are no other concurrent uses of the class.

Remarks

When a **CPopClient** object goes out of scope, the destructor is automatically called to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all handles that were created for the client session are destroyed.

The destructor is not called explicitly by the application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CPopClient

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CPopClient::AttachHandle Method

```
VOID AttachHandle(
   HCLIENT hClient
);
```

The **AttachHandle** method attaches the specified client handle to the current instance of the class.

Parameters

hClient

The handle to the client session that will be attached to the current instance of the class object.

Return Value

None.

Remarks

This method is used to attach a client handle created outside of the class using the SocketTools API. Once the client handle is attached to the class, the other class member functions may be used with that client session.

If a client handle has already been created for the class, that handle will be released when the new handle is attached to the class object. If you want to prevent the previous client session from being terminated, you must call the **DetachHandle** method. Failure to release the detached handle may result in a resource leak in your application.

Note that the ***hClient*** parameter is presumed to be a valid client handle and no checks are performed to ensure that the handle is valid. Specifying an invalid client handle will cause subsequent method calls to fail.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

See Also

AttachThread, DetachHandle, GetHandle

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CPopClient::AttachThread Method

```
DWORD AttachThread(
   DWORD dwThreadId
);
```

The **AttachThread** method attaches the specified client handle to another thread.

Parameters

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the method succeeds, the return value is the thread ID of the previous owner. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

When a client handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in a client application to create the client handle, and then pass that handle to another worker thread. The **AttachThread** method can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the method, the original owner of the handle can be restored before the worker thread terminates.

This method should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **AttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **Cancel** method and then release the handle after the blocking method exits and control is returned to the current thread.

Note that the ***dwThreadId*** parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the client handle used by the class until the destructor is called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

See Also

AttachHandle, Cancel, Connect, DetachHandle, Disconnect, GetHandle

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CPopClient::Cancel Method

```
INT Cancel();
```

The **Cancel** method cancels any outstanding blocking operation in the client, causing the blocking method to fail. The application may then retry the operation or terminate the client session.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

When the **Cancel** method is called, the blocking method will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

See Also

IsBlocking

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CPopClient::ChangePassword Method

```
BOOL ChangePassword(
   LPCTSTR lpszUserName,
   LPCTSTR lpszOldPassword,
   LPCTSTR lpszNewPassword
);
```

The **ChangePassword** method changes the account password for the specified user.

Parameters

lpszUserName

Pointer to a string which specifies the user name of the account who's password will be changed. It is not required that this be the same user name that was used to login to the mail server.

lpszOldPassword

Pointer to a string which specifies the current account password.

lpszNewPassword

Pointer to a string which specifies the new account password. When the method returns, the user's mailbox password will be set to this value.

Return Value

If the method succeeds, it will return a non-zero value. If the method fails, it will return zero. To get extended error information, call **GetLastError**.

Remarks

The **ChangePassword** method is used to change the password associated with the specified account on the server. The method establishes a connection to a separate service running on the server, and does not use the POP3 protocol. For this method to succeed, the server must be configured to allow password changes using the "poppass" service, running on port 106.

Because passwords are sent over the network as clear text, this service is considered to be insecure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

Connect, Login

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CPopClient::CloseMessage Method

```
INT CloseMessage(
   HCLIENT hClient
);
```

The **CloseMessage** method closes the current message that has been opened or created.

Parameters

hClient

Handle to the client session.

Return Value

If the method succeeds, the return value is the server result code. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

If an message is being created, this method actually submits the message to the server. Note that the client application is responsible for generating the message headers as well as the body of the message. News messages conform to the same general characteristics of an email message.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

CPopClient::Command Method

```
INT Command(
   LPCTSTR lpszCommand,
   LPCTSTR lpszParameter,
   BOOL bMultiLine
);
```

The **Command** method sends a command to the server, and returns the result code back to the caller. This method is typically used for site-specific commands not directly supported by the class.

Parameters

lpszCommand

The command which will be executed by the server.

lpszParameter

An optional command parameter. If the command requires more than one parameter, then they should be combined into a single string, with a space separating each parameter. If the command does not accept any parameters, this value may be NULL.

bMultiLine

An optional boolean argument used to specify if multiple lines of data will be returned by the server as the result of the command. Unlike a single line response, which consists of a result code and result string, a multi-line response consists of one or more lines of text, terminated by a special end-of-data marker. If this argument is omitted, ***bMultiLine*** is FALSE.

Return Value

If the method succeeds, the return value is the result code returned by the server. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

A list of valid commands can be found in the technical specification for the protocol. Many servers will list supported commands when the HELP command is used.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib
Unicode: Implemented as Unicode and ANSI versions

CPopClient::Connect Method

```
BOOL Connect(
   LPCTSTR lpszRemoteHost,
   UINT nRemotePort,
   UINT nTimeout,
   DWORD dwOptions
);
```

The **Connect** method is used to establish a connection with the server.

Parameters

lpszRemoteHost

The name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on. A value of zero specifies that the default port number should be used. For standard connections, the default port number is 110. For secure connections, the default port number is 995. If the secure port number is specified, an implicit TLS connection will be established by default.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
POP_OPTION_NONE	No connection options specified. A standard connection to the server will be established using the specified host name and port number.
POP_OPTION_LINEBREAK	Message data that is received from the server is read as individual lines of text terminated by a carriage return and linefeed control sequence. This option can be useful for applications that need to use the lower level network I/O functions and must process the message text on a line-by-line basis. This option is not recommended for most applications because it can have a negative impact on performance when retrieving large messages from the server.
POP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
POP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server

	certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
POP_OPTION_SECURE	This option specifies that a secure connection should be established with the server and requires that the server support the TLS protocol. This option is the same as specifying POP_OPTION_SECURE_EXPLICIT, which initiates the secure session using the STLS command.
POP_OPTION_SECURE_EXPLICIT	This option specifies the client should attempt to establish a secure connection with the server. The server must support secure connections using the TLS protocol and the STLS command.
POP_OPTION_SECURE_IMPLICIT	This option specifies the client should attempt to establish a secure connection with the server. It should only be used when the server expects an implicit TLS connection or does not implement RFC 2595 where the STLS command is used to negotiate a secure connection with the server.
POP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
POP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
POP_OPTION_FREETHREAD	This option specifies that this instance of the class may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the class instance is synchronized across multiple threads.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method will block the current thread until a connection has been established or the timeout period has elapsed. To prevent it from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling the **Connect** method in that

thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each connection.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the class instance is initially attached to the thread that created it. From that point on, until the handle is released, only the owner may call methods using that instance of the class. The ownership of the class instance may be transferred from one thread to another using the **AttachThread** method.

Specifying the POP_OPTION_FREETHREAD option enables any thread to call any method in that instance of the class, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the class instance is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same instance.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib
Unicode: Implemented as Unicode and ANSI versions

CPopClient::CreateSecurityCredentials Method

```
BOOL CreateSecurityCredentials(
   DWORD dwProtocol,
   DWORD dwOptions,
   LPCTSTR lpszUserName,
   LPCTSTR lpszPassword,
   LPCTSTR lpszCertStore,
   LPCTSTR lpszCertName
);

BOOL CreateSecurityCredentials(
   LPCTSTR lpszCertStore,
   LPCTSTR lpszCertName
);

BOOL CreateSecurityCredentials(
   LPCTSTR lpszCertName
);
```

The **CreateSecurityCredentials** method creates security credentials for the client session.

Parameters

dwProtocol

A bitmask of supported security protocols. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_TLS	Either the TLS 1.2 or 1.3 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers which reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows

	Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwOptions

A value which specifies one or more options. This member is constructed by using a bitwise operator with any of the following values:

Value	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

lpszUserName

A null-terminated string which specifies the certificate owner's username. A value of NULL specifies that no username is required. Currently this parameter is not used and any value specified will be ignored.

lpszPassword

A null-terminated string which specifies the certificate owner's password. A value of NULL specifies that no password is required. This parameter is only used if a PKCS #12 (PFX) certificate file is specified and that certificate has been secured with a password. This value will be ignored the current user or local machine certificate store is specified.

lpszCertStore

A null-terminated string which specifies the name of the certificate store to open. A certificate store

is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A null-terminated string which specifies the name of the certificate to use. The method will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the method will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the method will return an error indicating that the certificate could not be found.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

A client application only needs to call this method if the server requires that the client provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The ***dwOptions*** parameter should be set to CREDENTIAL_STORE_FILENAME and the ***lpszCertStore*** parameter should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS #12.These certificate files typically have an extension of .pfx or .p12. If a password was specified when the certificate was

created, it must be provided in the *lpszPassword* parameter or the library will be unable to access the certificate.

Note that the *lpszUserName* and *lpszPassword* parameters are optional values which are used to access the certificate store or client certificate. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session. In most cases, these parameters can be NULL or omitted.

Example

```
pClient->CreateSecurityCredentials(
            SECURITY_PROTOCOL_DEFAULT,
            0,
            NULL,
            NULL,
            lpszCertStore,
            lpszCertName);

bConnected = pClient->Connect(lpszHostName,
                              POP_PORT_SECURE,
                              POP_TIMEOUT,
                              POP_OPTION_SECURE);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib
Unicode: Implemented as Unicode and ANSI versions

CPopClient::DeleteMessage Method

```
INT DeleteMessage(
   UINT nMessage
);
```

The **DeleteMessage** method marks the specified message for deletion from the mailbox.

Parameters

nMessage

Number of message to delete from the server. This value must be greater than zero. The first message in the mailbox is message number one.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

This method only marks the message for deletion. The message is not actually deleted until the user disconnects from the server. To prevent one or more marked messages from actually being deleted from the mailbox, call the **Reset** method to reset the client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetMessage, GetMessageCount, Reset

CPopClient::DeleteSecurityCredentials Method

```
VOID DeleteSecurityCredentials();
```

The **DeleteSecurityCredentials** method releases the security credentials for the current session.

Parameters

None.

Return Value

None.

Remarks

This method can be used to release the memory allocated to the client or server credentials after a secure connection has been terminated. The security credentials are released when the class destructor is called, so it is normally not required that the application explicitly call this method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CreateSecurityCredentials

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CPopClient::DetachHandle Method

```
HCLIENT DetachHandle();
```

The **DetachHandle** method detaches the client handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the client handle associated with the current instance of the class object. If there is no active client session, the value INVALID_CLIENT will be returned.

Remarks

This method is used to detach a client handle created by the class for use with the SocketTools API. Once the client handle is detached from the class, no other class member functions may be called. Note that the handle must be explicitly released at some later point by the process or a resource leak will occur.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

See Also

AttachHandle, GetHandle

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CPopClient::DisableEvents Method

```
INT DisableEvents();
```

The **DisableEvents** method disables the event notification mechanism, preventing subsequent event notification messages from being posted to the application's message queue.

This method has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **DisableEvents** method is used to disable event message posting for the specified client session. Although this will immediately prevent any new events from being generated, it is possible that messages could be waiting in the message queue. Therefore, an application must be prepared to handle client event messages after this method has been called.

This method is automatically called if the client has event notification enabled, and the **Disconnect** method is called. The same issues regarding outstanding event messages also applies in this situation, requiring that the application handle event messages that may reference a client handle that is no longer valid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

See Also

EnableEvents, RegisterEvent

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CPopClient::DisableTrace Method

```
BOOL DisableTrace();
```

The **DisableTrace** method disables the logging of network function calls.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, a value of zero is returned.

Remarks

This method will disable output to the log file for the current thread or process, depending on the flags used when logging was enabled. If this method is not called, the resources that were allocated for the logging session will be released when the process ends.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

See Also

EnableTrace

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CPopClient::Disconnect Method

```
VOID Disconnect();
```

The **Disconnect** method terminates the connection with the server, closing the socket and releasing the memory allocated for the client session.

Parameters

None.

Return Value

None.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

Connect, IsConnected

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CPopClient::EnableEvents Method

```
INT EnableEvents(
   HWND hEventWnd,
   UINT uEventMsg
);
```

The **EnableEvents** method enables event notifications using Windows messages.

This method has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Applications should use the **RegisterEvent** method to register an event handler which is invoked when an event occurs.

Parameters

hEventWnd

Handle to the window which will receive the client notification messages. This parameter must specify a valid window handle. If a NULL handle is specified, event notification will be disabled.

uEventMsg

The message that is received when a client event occurs. This value must be greater than 1024.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **EnableEvents** method is used to request that notification messages be posted to the specified window whenever a client event occurs. This allows an application to monitor the status of different client operations, such as a file transfer.

The *wParam* argument will contain the client handle, the low word of the *lParam* argument will contain the event ID, and the high word will contain any error code. If no error has occurred, the high word will always have a value of zero. The following events may be generated:

Value	Description
POP_EVENT_CONNECT	The connection to the server has completed. The high word of the *lParam* parameter should be checked, since this notification message will be posted if an error has occurred.
POP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
POP_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
POP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This

	event is only generated if the client is in asynchronous mode.
POP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
POP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
POP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.
POP_EVENT_PROGRESS	The client is in the process of sending or receiving a file on the data channel. This event is called periodically during a transfer so that the client can update any user interface components such as a status control or progress bar.

It is not required that the client be placed in asynchronous mode in order to receive command and progress event notifications. To disable event notification, call the **DisableEvents** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

See Also

DisableEvents, RegisterEvent

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CPopClient::EnableTrace Method

```
BOOL EnableTrace(
   LPCTSTR lpszTraceFile,
   DWORD dwTraceFlags
);
```

The **EnableTrace** method enables the logging of network function calls to a file.

Parameters

lpszTraceFile

A null-terminated string which specifies the name of the logfile which will be appended to or created. It is recommended that this file always specify an absolute path to avoid any ambiguity. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
TRACE_INFO	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
TRACE_ERROR	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
TRACE_HEXDUMP	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
TRACE_TRUNCATE	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for

	multithreaded applications that are using worker threads.

Return Value

If the method succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the log file cannot be created.

Remarks

Logging is enabled and disabled at the thread or process level, depending on the flags passed to this method, and is not associated with a specific class instance. When logging is enabled, the information is appended to the specified file. If the file does not exist, it will be created. To limit the size of the file, enable and disable logging only around those sections of code that you wish to debug. If you do not provide a full path to the file, it will be relative to the current working directory for the process. This can produce unexpected results in multithreaded applications because the current directory is global to the entire process and can be changed by any thread at any time.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

The TRACE_HEXDUMP option can generate very large files because it includes all of the data exchanged between your application and the remote host. The TRACE_TRUNCATE option is only evaluated when logging is first enabled for a thread or process. If logging is already active, specifying this option will have no effect.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "**0x**". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxxx:xxxx::xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, a connection is being made to a system with the IPv4 address 192.0.0.1 on port 1234.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib
Unicode: Implemented as Unicode and ANSI versions

CPopClient::FreezeEvents Method

```
INT FreezeEvents(
   BOOL bFreeze
);
```

The **FreezeEvents** method is used to suspend and resume event handling by the client.

Parameters

bFreeze

A non-zero value specifies that event handling should be suspended by the client. A zero value specifies that event handling should be resumed.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

This method should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all client events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if the client has suspended event handling, and four read events occur, once event handling is resumed only one of those read events will be posted to the client. This prevents the application from being flooded by a potentially large number of queued events.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

DisableEvents, EnableEvents, RegisterEvent

CPopClient::GetErrorString Method

```
INT GetErrorString(
   DWORD dwErrorCode,
   LPTSTR lpszDescription,
   INT nMaxLength
);

INT GetErrorString(
   DWORD dwErrorCode,
   CString& strDescription
);
```

The **GetErrorString** method is used to return a description of a specific error code. Typically this is used in conjunction with the **GetLastError** method for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

The buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length. An alternate form of the method accepts a **CString** variable which will contain the error description.

nMaxLength

The maximum number of characters that may be copied into the description buffer.

Return Value

If the method succeeds, the return value is the length of the description string. If the method fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the method is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetLastError, SetLastError, ShowError

CPopClient::GetHandle Method

```
HCLIENT GetHandle();
```

The **GetHandle** method returns the client handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the client handle associated with the current instance of the class object. If there is no active client session, the value INVALID_CLIENT will be returned.

Remarks

This method is used to obtain the client handle created by the class for use with the SocketTools API.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

See Also

CPopClient::GetHeaderValue Method

```
INT GetHeaderValue(
   UINT nMessageId,
   LPCTSTR lpszHeader,
   LPTSTR lpszValue,
   INT nMaxLength
);

INT GetHeaderValue(
   UINT nMessageId,
   LPCTSTR lpszHeader,
   CString& strValue
);
```

The **GetHeaderValue** method returns the value of a header field in the specified message.

Parameters

nMessageId

Number of message to retrieve header value from. This value must be greater than zero. The first message in the mailbox is message number one.

lpszHeader

Pointer to a string which specifies the message header to retrieve. The colon should not be included in this string.

lpszValue

Pointer to a string buffer that will contain the value of the specified message header.

nMaxLength

The maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the method succeeds, the method returns the length of the header field value. If the header field is not present in the message, the method will return a value of zero. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetHeaderValue** method returns the value of a header field from the specified message. This allows an application to be able to easily determine the value of a header (such as the sender, or the subject of the message) without downloading the entire message header and parsing the contents.

This method uses the XTND XLST command, which is an extension to the POP3 protocol. If this command is not supported by the server, the method will attempt to retrieve the entire message header and return the value for the specified header field. This enables an application to use this method even if the server does not support command extensions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

Unicode: Implemented as Unicode and ANSI versions

CPopClient::GetLastError Method

```
DWORD GetLastError();

DWORD GetLastError(
   CString& strDescription
);
```

Parameters

strDescription

A string which will contain a description of the last error code value when the method returns. If no error has been set, or the last error code has been cleared, this string will be empty.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **SetLastError** method. The Return Value section of each reference page notes the conditions under which the method sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **GetLastError** method immediately when a method's return value indicates that an error has occurred. That is because some methods call **SetLastError**(0) when they succeed, clearing the error code set by the most recently failed method.

Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or POP_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

The description of the error code is the same string that is returned by the **GetErrorString** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

See Also

GetErrorString, SetLastError, ShowError

CPopClient::GetMessage Method

```
INT GetMessage(
   LONG nMessageId,
   LPBYTE lpBuffer,
   LPDWORD lpdwLength
);

INT GetMessage(
   LONG nMessageId,
   HGLOBAL *lpBuffer,
   LPDWORD lpdwLength
);

INT GetMessage(
   LONG nMessageId,
   CString& strBuffer
);
```

The **GetMessage** method retrieves the specified message and copies the contents to a local buffer.

Parameters

nMessageId

Number of message to retrieve from the server. This value must be greater than zero.

lpBuffer

A buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the method returns.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the ***lpBuffer*** parameter. If the ***lpBuffer*** parameter points to a global memory handle, the length value should be initialized to zero. When the method returns, this value will be updated with the actual length of the file that was downloaded.

Return Value

If the method succeeds, the return value is the server result code. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetMessage** method is used to retrieve an message from the server and copy it into a local buffer. The method may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the contents of the message. In this case, the ***lpBuffer*** parameter will point to the buffer that was allocated, the value that the ***lpdwLength*** parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the ***lpBuffer*** parameter point to a global memory handle which will contain the message data when the method returns. In this case, the value that the ***lpdwLength*** parameter points to must be initialized to zero. It is important to note that the memory handle returned by the method must be freed by the application, otherwise a memory leak will occur. See the example code below.

This method will cause the current thread to block until the complete message has been retrieved, a timeout occurs or the operation is canceled. During the transfer, the POP_EVENT_PROGRESS event

will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **EnableEvents**, or by registering a callback function using the **RegisterEvent** method.

To determine the current status of a transfer while it is in progress, use the **GetTransferStatus** method.

Example

```
HGLOBAL hgblBuffer = (HGLOBAL)NULL;
LPBYTE lpBuffer = (LPBYTE)NULL;
DWORD cbBuffer = 0;

// Return the message into block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgblBuffer parameter
nResult = pClient->GetMessage(nMessageId, &hgblBuffer, &cbBuffer);

if (nResult != POP_ERROR)
{
    // Lock the global memory handle, returning a pointer to the
    // message text
    lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

CPopClient::GetMessageCount Method

```
INT GetMessageCount(
   UINT *lpnLastMessage,
   DWORD *lpdwMailboxSize
);
```

The **GetMessageCount** method returns the number of messages available in the mailbox, the last valid message number in the mailbox and the current size of the mailbox in bytes.

Parameters

lpnLastMessage

Address of a variable that receives the number of the last valid message in the mailbox. If a NULL value is specified, this argument is ignored.

lpdwMailboxSize

Address of a variable that receives the current size of the mailbox. This value will decrease as messages are deleted. If a NULL value is specified, this argument is ignored.

Return Value

If the method succeeds, it returns the number of messages that are currently available. If no messages are available, either because the mailbox is empty or all of the messages have been deleted, this method will return zero. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

See Also

DeleteMessage, GetHeaderValue, GetMessage, GetMessageHeaders, StoreMessage

CPopClient::GetMessageHeaders Method

```
INT GetMessageHeaders(
   LONG nMessageId,
   LPBYTE lpHeaders,
   LPDWORD lpdwLength
);

INT GetMessageHeaders(
   LONG nMessageId,
   HGLOBAL *lpHeaders,
   LPDWORD lpdwLength
);

INT GetMessageHeaders(
   LONG nMessageId,
   CString& strHeaders
);
```

The **GetMessageHeaders** method retrieves the headers for the specified message from the server.

Parameters

nMessageId

Number of message to retrieve from the server. This value must be greater than zero.

lpHeaders

A buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the method returns.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the ***lpHeaders*** parameter. If the ***lpHeaders*** parameter points to a global memory handle, the length value should be initialized to zero. When the method returns, this value will be updated with the actual length of the message that was downloaded.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetMessageHeaders** method is used to retrieve an message header block from the server and copy it into a local buffer. The method may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the contents of the file. In this case, the ***lpHeaders*** parameter will point to the buffer that was allocated, the value that the ***lpdwLength*** parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the ***lpHeaders*** parameter point to a global memory handle which will contain the message headers when the method returns. In this case, the value that the ***lpdwLength*** parameter points to must be initialized to zero. It is important to note that the memory handle returned by the method must be freed by the application, otherwise a memory leak will occur.

This method will cause the current thread to block until the transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the POP_EVENT_PROGRESS event will be periodically

fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **EnableEvents**, or by registering a callback function using the **RegisterEvent** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

See Also

GetHeaderValue, GetMessage, GetMessageId, OpenMessage

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CPopClient::GetMessageId Method

```
INT GetMessageId(
   UINT nMessageId,
   LPTSTR lpszMessageId,
   INT nMaxLength
);

INT GetMessageId(
   UINT nMessageId,
   CString& strMessageId
);
```

The **GetMessageId** method returns the message identifier for the specified message.

Parameters

nMessageId

Number of message to retrieve the unique identifier for. This value must be greater than zero. The first message in the mailbox is message number one.

lpszMessageId

Address of a string buffer to receive the message identifier. This should be at least 64 bytes in length. This argument may also be a **CString** object which will contain the message identifier when the method returns.

nMaxLength

The maximum length of the string buffer.

Return Value

If the method succeeds, the return value is the length of the unique identifier string. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetMessageId** method returns the message identifier from the Message-ID header of the specified message. The returned value is a typically a string which specifies the domain, date and timestamp for the message that is created when the message is submitted to the mail server for delivery. To obtain a unique identifier for the message in the mailbox, it is recommended that you use the **GetMessageUID** method instead.

This method uses the XTND XLST command to obtain the value of the "Message-ID" header field. If this command is not supported by the server, the method will attempt to retrieve the entire message header and return the header value . This enables an application to use this method even if the server does not support command extensions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetHeaderValue, GetMessage, GetMessageHeaders, GetMessageSender, GetMessageUID

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CPopClient::GetMessageSender Method

```
INT GetMessageSender(
   UINT nMessageId,
   LPTSTR lpszAddress,
   INT nMaxLength
);

INT GetMessageSender(
   UINT nMessageId,
   CString& strAddress
);
```

The **GetMessageSender** method returns the sender's address for the specified message.

Parameters

nMessageId

Number of message to retrieve header value from. This value must be greater than zero. The first message in the mailbox is message number one.

lpszAddress

Pointer to a string buffer that will contain the address of the message sender. This argument may also be a **CString** object which will contain the address when the method returns.

nMaxLength

The maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the method succeeds, the method returns the length of the address. If the sender cannot be determined, the method will return a value of zero. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetMessageSender** method returns the email address of the user who sent the specified message. This allows an application to be able to easily determine the sender, without downloading the entire header block or contents of the message.

This method uses the XSENDER command, which is an extension to the POP3 protocol, to determine the address of the authenticated sender of the message. If the command is not supported, or the server was unable to authenticate the sender, the method will use the XTND XLST command to obtain the value of the "From" header field. If this command is not supported by the server, the method will attempt to retrieve the entire message header and return the value for the specified header field. This enables an application to use this method even if the server does not support command extensions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib
Unicode: Implemented as Unicode and ANSI versions

CPopClient::GetMessageSize Method

```
DWORD GetMessageSize(
   UINT nMessageId
);
```

The **GetMessageSize** method returns the size of the specified message.

Parameters

nMessageId

Number of message to retrieve size of. This value must be greater than zero. The first message in the mailbox is message number one.

Return Value

If the method succeeds, the return value is the size of the specified message in bytes. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

See Also

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CPopClient::GetMessageUID Method

```
INT GetMessageUID(
   UINT nMessageId,
   LPTSTR lpszMessageUID,
   INT nMaxLength
);

INT GetMessageUID(
   UINT nMessageId,
   CString& strMessageUID
);
```

The **GetMessageUID** method returns the unique identifier (UID) for the specified message in the current mailbox.

Parameters

nMessageId

Number of message to retrieve the unique identifier for. This value must be greater than zero. The first message in the mailbox is message number one.

lpszMessageUID

Address of a string buffer to receive the unique identifier for the specified message. This should be at least 64 bytes in length. This argument may also be a **CString** object which will contain the UID string when the method returns.

nMaxLength

The maximum length of the string buffer for the message UID.

Return Value

If the method succeeds, it returns a non-zero value. If no unique identifier is assigned to the message, the method will return zero. If an error occurs, the method returns POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetMessageUID** method returns the unique message identifier for the specified message. The returned value is a string which can be used to uniquely identify a specific message in the mailbox across multiple client sessions. This is commonly used by mail clients to determine if they have already retrieved a message from the server in a previous session. The UID can also be used as a key or component of the file name to reference the message after it has been stored on the local system.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

See Also

GetHeaderValue, GetMessage, GetMessageHeaders, GetMessageId, GetMessageSender

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CPopClient::GetResultCode Method

```
BOOL GetResultCode();
```

The **GetResultCode** method reads the result code returned by the server in response to a command. The result code is a boolean value, and indicates if the operation succeeded or failed.

Parameters

None.

Return Value

If the previous command was successful, the function returns a non-zero value. If the previous command failed, the function returns zero. To get extended error information, call **GetLastError**.

Remarks

Unlike most other Internet application protocols, the Post Office Protocol does not return numeric result codes to indicate success or failure. If a command is successful, the server will respond with the string "+OK" and this is indicated by the **GetResultCode** method returning a non-zero value. If the command fails, the server will respond with the string "-ERR" along with a description of the error, and this is indicated by the method returning a value of zero. The description of the error returned by the server can be obtained by calling the **GetResultString** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

See Also

Command, GetResultString

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CPopClient::GetResultString Method

```
INT GetResultString(
   LPTSTR lpszResult,
   INT cbResult
);

INT GetResultString(
   CString& strResult
);
```

The **GetResultString** method returns the last message sent by the server along with the result code.

Parameters

lpszResult

The buffer that will contain the result string returned by the server. An alternate form of the method accepts a **CString** argument which will contain the result string returned by the server.

cbResult

The maximum number of characters that may be copied into the result string buffer, including the terminating null character.

Return Value

If the method succeeds, the return value is the length of the result string. If a value of zero is returned, this means that no result string was sent by the server. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetResultString** method is most useful when an error occurs because the server will typically include a brief description of the cause of the error. This can then be parsed by the application or displayed to the user. The result string is updated each time the client sends a command to the server and then calls **GetResultCode** to obtain the result code for the operation.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib
Unicode: Implemented as Unicode and ANSI versions

CPopClient::GetSecurityInformation Method

```
BOOL GetSecurityInformation(
   LPSECURITYINFO lpSecurityInfo
);
```

The **GetSecurityInformation** method returns security protocol, encryption and certificate information about the current client connection.

Parameters

lpSecurityInfo

A pointer to a SECURITYINFO structure which contains information about the current client connection. The *dwSize* member of this structure must be initialized to the size of the structure before passing the address of the structure to this method.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method is used to obtain security related information about the current client connection to the server. It can be used to determine if a secure connection has been established, what security protocol was selected, and information about the server certificate. Note that a secure connection has not been established, the *dwProtocol* structure member will contain the value SECURITY_PROTOCOL_NONE.

Example

```
// Notifies the user if the connection is secure or not
SECURITYINFO securityInfo;
securityInfo.dwSize = sizeof(SECURITYINFO);

if (pClient->GetSecurityInformation(&securityInfo))
{
    if (securityInfo.dwProtocol == SECURITY_PROTOCOL_NONE)
    {
        MessageBox(NULL, _T("The connection is not secure"),
                         _T("Connection"), MB_OK);
    }
    else
    {
        if (securityInfo.dwCertStatus == SECURITY_CERTIFICATE_VALID)
        {
            MessageBox(NULL, _T("The connection is secure"),
                             _T("Connection"), MB_OK);
        }
        else
        {
            MessageBox(NULL, _T("The server certificate not valid"),
                             _T("Connection"), MB_OK);
        }
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib
Unicode: Implemented as Unicode and ANSI versions

CPopClient::GetStatus Method

```
INT GetStatus();
```

The **GetStatus** method the current status of the client session.

Parameters

None.

Return Value

If the method succeeds, the return value is the client status code. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetStatus** method returns a numeric code which identifies the current state of the client session. The following values may be returned:

Value	Description
POP_STATUS_UNUSED	No connection has been established.
POP_STATUS_IDLE	The client is current idle and not sending or receiving data.
POP_STATUS_CONNECT	The client is establishing a connection with the server.
POP_STATUS_READ	The client is reading data from the server.
POP_STATUS_WRITE	The client is writing data to the server.
POP_STATUS_DISCONNECT	The client is disconnecting from the server.

In a multithreaded application, any thread in the current process may call this method to obtain status information for the specified client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

CPopClient::GetTimeout Method

```
INT GetTimeout();
```

The **GetTimeout** method returns the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the method will fail and return to the caller.

Parameters

None.

Return Value

If the method succeeds, the return value is the timeout period in seconds. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The timeout value is only used with blocking client connections. A value of zero indicates that the default timeout period of 20 seconds should be used.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

See Also

Connect, IsReadable, IsWritable, Read, SetTimeout, Write

CPopClient::GetTransferStatus Method

```
INT GetTransferStatus(
   LPPOPTRANSFERSTATUS lpStatus
);
```

The **GetTransferStatus** method returns information about the current file transfer in progress.

Parameters

lpStatus

A pointer to an POPTRANSFERSTATUS structure which contains information about the status of the current file transfer.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetTransferStatus** method returns information about the current file transfer, including the average number of bytes transferred per second and the estimated amount of time until the transfer completes. If there is no file currently being transferred, this method will return the status of the last successful transfer made by the client.

In a multithreaded application, any thread in the current process may call this method to obtain status information for the specified client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

See Also

EnableEvents, GetStatus, RegisterEvent

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CPopClient::IsBlocking Method

```
BOOL IsBlocking();
```

The **IsBlocking** method is used to determine if the client is currently performing a blocking operation.

Parameters

None.

Return Value

If the client is performing a blocking operation, the method returns a non-zero value. If the client is not performing a blocking operation, or the client handle is invalid, the method returns zero.

Remarks

Because a blocking operation can allow the application to be re-entered (for example, by pressing a button while the operation is being performed), it is possible that another blocking method may be called while it is in progress. Since only one thread of execution may perform a blocking operation at any one time, an error would occur. The **IsBlocking** method can be used to determine if the client is already blocked, and if so, take some other action (such as warning the user that they must wait for the operation to complete).

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib
Unicode: Implemented as Unicode and ANSI versions

CPopClient::IsConnected Method

```
BOOL IsConnected();
```

The **IsConnected** method is used to determine if the client is currently connected to a server.

Parameters

None.

Return Value

If the client is connected to a server, the method returns a non-zero value. If the client is not connected, or the client handle is invalid, the method returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

CPopClient::IsInitialized Method

```
BOOL IsInitialized();
```

The **IsInitialized** method returns whether or not the class object has been successfully initialized.

Parameters

None.

Return Value

This method returns a non-zero value if the class object has been successfully initialized. A return value of zero indicates that the runtime license key could not be validated or the networking library could not be loaded by the current process.

Remarks

When an instance of the class is created, the class constructor will attempt to initialize the component with the runtime license key that was created when SocketTools was installed. If the constructor is unable to validate the license key or load the networking libraries, this initialization will fail.

If SocketTools was installed with an evaluation license, the application cannot be redistributed to another system. The class object will fail to initialize if the application is executed on another system, or if the evaluation period has expired. To redistribute your application, you must purchase a development license which will include the runtime key that is needed to redistribute your software to other systems. Refer to the Developer's Guide for more information.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

CPopClient, IsBlocking, IsConnected

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CPopClient::IsReadable Method

```
BOOL IsReadable(
   INT nTimeout,
   LPDWORD lpdwAvail
);
```

The **IsReadable** method is used to determine if data is available to be read from the server.

Parameters

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

lpdwAvail

A pointer to an unsigned integer which will contain the number of bytes available to read. This parameter may be NULL if this information is not required.

Return Value

If the client can read data from the server within the specified timeout period, the method returns a non-zero value. If the client cannot read any data, the method returns zero.

Remarks

On some platforms, this value will not exceed the size of the receive buffer (typically 64K bytes). Because of differences between TCP/IP stack implementations, it is not recommended that your application exclusively depend on this value to determine the exact number of bytes available. Instead, it should be used as a general indicator that there is data available to be read.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

See Also

CPopClient::IsWritable Method

```
BOOL IsWritable(
   INT nTimeout
);
```

The **IsWritable** method is used to determine if data can be written to the server.

Parameters

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

Return Value

If the client can write data to the server within the specified timeout period, the method returns a non-zero value. If the client cannot write any data, the method returns zero.

Remarks

Although this method can be used to determine if some amount of data can be sent to the remote process it does not indicate the amount of data that can be written without blocking the client. In most cases, it is recommended that large amounts of data be broken into smaller logical blocks, typically some multiple of 512 bytes in length.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

CPopClient::Login Method

```
INT Login(
   LPCTSTR lpszUserName,
   LPCTSTR lpszPassword,
   UINT nAuthType
);
```

The **Login** method authenticates the specified user in on the server. This method must be called after the connection has been established, and before attempting to retrieve messages or perform any other method on the server.

Parameters

lpszUserName

A null-terminated string which specifies the user name to be used to authenticate the current client session. For many service providers, the user name is the full email address of the user which owns the mailbox. In some cases, this may only be the portion of their email address before the domain name.

lpszPassword

A null-terminated string which specifies the password to be used when authenticating the current client session. If you are using the POP_AUTH_XOAUTH2 or POP_AUTH_BEARER authentication methods, this parameter is not a password, instead it specifies the OAuth 2.0 bearer token provided by the mail service.

nAuthType

Identifies the type of authentication that should be used when the client logs in to the mail server. The following authentication methods are supported:

Value	Description
POP_AUTH_DEFAULT	The default authentication scheme which sends the username and password as cleartext to the server. Because the user credentials are not encrypted, this method should only be used over a secure connection. This is the same as specifying POP_AUTH_PASS as the authentication method.
POP_AUTH_PASS	The username and password is sent to the server using the USER and PASS commands. This authentication method is supported by most servers and is the default authentication type. The credentials are not encrypted and this method should only be used over secure connections.
POP_AUTH_APOP	The APOP authentication method which uses an MD5 digest of the password. This method has been deprecated is not supported by all servers. It should only be used if required by legacy mail servers which do not support the SASL authentication methods.
POP_AUTH_LOGIN	This authentication type will use the LOGIN method to authenticate the client session. This encodes the username and password in a specific format, but the credentials are not encrypted. It should be used over a secure connection. The server must support the Simple Authentication and Security Layer (SASL) mechanism as defined in RFC 4422.

POP_AUTH_PLAIN	This authentication type will use the PLAIN method to authenticate the client session. This encodes the username and password in a specific format, but the credentials are not encrypted. It should be used over a secure connection. The server must support the PLAIN Simple Authentication and Security Layer (SASL) mechanism as defined in RFC 4616.
POP_AUTH_XOAUTH2	This authentication type will use the XOAUTH2 method to authenticate the client session. This authentication method does not require the user password, instead the *lpszPassword* parameter must specify the bearer token issued by the service provider. The application must provide a valid access token which has not expired, or this method will fail.
POP_AUTH_BEARER	This authentication type will use the OAUTHBEARER method to authenticate the client session as defined in RFC 7628. This authentication method does not require the user password, instead the *lpszPassword* parameter must specify the bearer token issued by the service provider. The application must provide a valid access token which has not expired, or this method will fail.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The POP_AUTH_LOGIN and POP_AUTH_PLAIN authentication methods require the mail server support the Simple Authentication and Security Layer (SASL) AUTH command as defined in RFC 5034. Most modern mail servers do support one or both of these methods, and they are generally preferred over the POP_AUTH_PASS method when possible. However, for backwards compatibility with legacy servers, the class will default to using POP_AUTH_PASS for client authentication.

You should only use an OAuth 2.0 authentication method if you understand the process of how to request the access token. Obtaining an access token requires registering your application with the mail service provider (e.g.: Microsoft or Google), getting a unique client ID associated with your application and then requesting the access token using the appropriate scope for the service. Obtaining the initial token will typically involve interactive confirmation on the part of the user, requiring they grant permission to your application to access their mail account.

The POP_AUTH_XOAUTH2 and POP_AUTH_BEARER authentication methods are similar, but they are not interchangeable. Both use an OAuth 2.0 bearer token to authenticate the client session, but they differ in how the token is presented to the server. It is currently preferable to use the XOAUTH2 method because it is more widely available and some service providers do not yet support the OAUTHBEARER method.

Your application should not store an OAuth 2.0 bearer token for later use. They have a relatively short lifespan, typically about an hour, and are designed to be used with that session. You should specify offline access as part of the OAuth 2.0 scope if necessary and store the refresh token provided by the service. The refresh token has a much longer validity period and can be used to obtain a new bearer token when needed.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

Connect, GetMessage, GetMessageCount

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CPopClient::OpenMessage Method

```
INT OpenMessage(
   UINT nMessageId
);
```

The **OpenMessage** method opens the specified message for reading.

Parameters

nMessageId

Number that specifies which message to open. This value must be greater than zero. The first message in the mailbox is message one.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **OpenMessage** method is used to begin the process of reading the contents of a message from the from the server. Similar to how a file is opened and read, this method is followed by one or more calls to the **Read** method. When the entire contents of the message has been read, the **CloseMessage** method is used to close the message, completing the transaction on the server.

This is a lower-level method which enables the application to process the message as the contents are being returned by the server. In general, it is recommended that most applications use the **GetMessage** method instead, which provides a simpler interface for retrieving the contents of a message.

It is important to note that you cannot use this method to read the partial contents of a message. Opening a message on the server begins a process where the entire message contents must be read and the message closed before the next command can be issued to the server. If you only want to obtain the headers for a message, use the **GetMessageHeaders** method instead.

Example

```
// Connect to the mail server using the default settings
if (popClient.Connect(strHostName))
{
    // Authenticate the user and display an error if the
    // server does not accept the username or password
    if (popClient.Login(strUserName, strPassword) == POP_ERROR)
    {
        popClient.ShowError();
        popClient.Disconnect();
        return;
    }

    // Open the specified message
    if (popClient.OpenMessage(nMessageId) == POP_ERROR)
    {
        popClient.ShowError();
        popClient.Disconnect();
        return;
    }
```

```
    CString strMessage;
    CString strBuffer;
    INT nResult;

    // Read the contents of the message in a loop; a return value
    // of zero indicates that there is no more data to read
    do
    {
        if ((nResult = popClient.Read(strBuffer)) > 0)
            strMessage = strMessage + strBuffer;
    }
    while (nResult > 0);

    // If an error occurred while reading reading the message,
    // display an error message
    if (nResult == POP_ERROR)
    {
        popClient.ShowError();
        popClient.Disconnect();
        return;
    }

    // Close the message and disconnect from the server
    popClient.CloseMessage();
    popClient.Disconnect();
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

See Also

CloseMessage, GetMessage, GetMessageHeaders, IsReadable, Read

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CPopClient::Read Method

```
INT Read(
   LPBYTE lpBuffer,
   INT cbBuffer
);

INT Read(
   CString& strBuffer,
   INT cbBuffer
);
```

The **Read** method reads the specified number of bytes from the client socket and copies them into the buffer. The data may be of any type, and is not terminated with a null character.

Parameters

lpBuffer

Pointer to the buffer in which the data will be copied. An alternate form of this method allows a **CString** variable to be passed and data read from the socket will be returned in that string.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

Return Value

If the method succeeds, the return value is the number of bytes actually read. A return value of zero indicates that the server has closed the connection and there is no more data available to be read. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

When **Read** is called and the client is in non-blocking mode, it is possible that the method will fail because there is no available data to read at that time. This should not be considered a fatal error. Instead, the application should simply wait to receive the next asynchronous notification that data is available.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

EnableEvents, IsBlocking, IsReadable, IsWritable, RegisterEvent, Write

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CPopClient::RegisterEvent Method

```
INT RegisterEvent(
   UINT nEventId,
   POPEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

The **RegisterEvent** method registers an event handler for the specified event.

Parameters

nEventId

An unsigned integer which specifies which event should be registered with the specified callback function. One of the following values may be used:

Value	Description
POP_EVENT_CONNECT	The connection to the server has completed.
POP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
POP_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
POP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
POP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
POP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
POP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.
POP_EVENT_PROGRESS	The client is in the process of sending or receiving a file on the data channel. This event is called periodically during a transfer so that the client can update any user interface components such as a status control or progress bar.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **PopEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Remarks

The **RegisterEvent** method associates a callback function with a specific event. The event handler is an **PopEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

This method is typically used to register an event handler that is invoked while a message is being retrieved. The POP_EVENT_PROGRESS event will only be generated periodically during the transfer to ensure the application is not flooded with event notifications. It is guaranteed that at least one POP_EVENT_PROGRESS notification will occur at the beginning of the transfer, and one at the end of the transfer when it has completed.

The callback function specified by the *lpEventProc* parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

The *dwParam* parameter is commonly used to identify the class instance which is associated with the event that has occurred. Applications will cast the **this** pointer to a DWORD_PTR value when calling this function, and then the event handler will cast it back to a pointer to the class instance. This gives the handler access to the class member variables and methods.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

See Also

CPopClient::Reset Method

```
BOOL Reset();
```

The **Reset** method resets the client state and resynchronizes with the server. This method is typically called after an unexpected error has occurred, or an operation has been canceled.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method will prevent any messages marked for deletion from actually being deleted from the mailbox. The client cannot be reset while the client is in a blocked state.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

See Also

Cancel, DeleteMessage, IsBlocking

CPopClient::SendMessage Method

```
INT SendMessage(
   LPCTSTR lpszMessage,
   INT nLength
);
```

The **SendMessage** method sends a message to the specified recipients.

Parameters

lpszMessage

Pointer to a string buffer which contains the message to be submitted to the mail server for delivery.

nLength

The length of the string buffer. This specifies the number of characters to be written to the mail server. This value must be greater than zero. If this value is -1, then the length of the string up to the terminating null character is used.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **SendMessage** method sends a message through the POP3 server using the XTND XMIT command. The specified file must be in the standard format as described in RFC 822, with the recipient addresses specified in the To: and Cc: header fields. Some servers may support blind carbon copies by using addresses specified in a Bcc: header field, and then removing those addresses from the header before delivering the message.

Note that not all POP3 servers support this command, and it is recommended that you use the Simple Mail Transfer Protocol (SMTP) for general mail delivery purposes.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetMessage, StoreMessage

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CPopClient::SetLastError Method

```
VOID SetLastError(
   DWORD dwErrorCode
);
```

The **SetLastError** method sets the last error code for the current thread. This method is typically used to clear the last error by specifying a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or POP_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

Applications can retrieve the value saved by this method by using the **GetLastError** method. The use of **GetLastError** is optional; an application can call the method to determine the specific reason for a method failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

See Also

GetErrorString, GetLastError, ShowError

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CPopClient::SetTimeout Method

```
INT SetTimeout(
   UINT nTimeout
);
```

The **SetTimeout** method sets the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the method will fail and return to the caller.

Parameters

nTimeout

The number of seconds to wait for a blocking operation to complete.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The timeout value is only used with blocking client connections.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

See Also

CPopClient::ShowError Method

```
INT ShowError(
   LPCTSTR lpszAppTitle,
   UINT uType,
   DWORD dwErrorCode
);
```

The **ShowError** method displays a message box which describes the specified error.

Parameters

lpszAppTitle

A null-terminated string which specifies the title of the message box that is displayed. If this argument is NULL or omitted, then the default title of "Error" will be displayed.

uType

An unsigned integer which specifies the type of message box that will be displayed. This is the same value that is used by the **MessageBox** method in the Windows API. If a value of zero is specified, then a message box with a single OK button will be displayed. Refer to that method for a complete list of options.

dwErrorCode

Specifies the error code that will be used when displaying the message box. If this argument is zero, then the last error that occurred in the current thread will be displayed.

Return Value

If the method is successful, the return value will be the return value from the **MessageBox** function. If the method fails, it will return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CPopClient::StoreMessage Method

```
INT StoreMessage(
   UINT nMessageId,
   LPCTSTR lpszFileName
);
```

The **StoreMessage** method stores a message in the specified file.

Parameters

nMessageId

Number of the message to retrieve. This value must be greater than zero. The first message in the mailbox is message number one.

lpszFileName

Pointer to a string which specifies the file that the message will be stored in. If an empty string or NULL pointer is passed as an argument, the message is copied to the system clipboard.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **StoreMessage** method provides a method of retrieving and storing a message on the local system. The contents of the message is stored as a text file, using the specified file name. This method always causes the caller to block until the entire message has been retrieved, even if the client has been put in asynchronous mode.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CPopClient::Write Method

```
INT Write(
   LPBYTE lpBuffer,
   INT cbBuffer
);

INT Write(
   LPCTSTR lpszBuffer
   INT cbBuffer
);
```

The **Write** method sends the specified number of bytes to the server.

Parameters

lpBuffer

The pointer to the buffer which contains the data that is to be sent to the server. In an alternate form of the method, the pointer is to a string.

cbBuffer

The number of bytes to send from the specified buffer. This value must be greater than zero, unless a pointer to a string buffer is passed as the parameter. In that case, if the value is -1, all of the characters in the string, up to but not including the terminating null character, will be sent to the server.

Return Value

If the method succeeds, the return value is the number of bytes actually written. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The return value may be less than the number of bytes specified by the ***cbBuffer*** parameter. In this case, the data has been partially written and it is the responsibility of the client application to send the remaining data at some later point. For non-blocking clients, the client must wait for the next asynchronous notification message before it resumes sending data.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib
Unicode: Implemented as Unicode and ANSI versions

- POPTRANSFERSTATUS
- SECURITYCREDENTIALS
- SECURITYINFO
- SYSTEMTIME

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

POPTRANSFERSTATUS

This structure is used by the GetTransferStatus method to return information about a message transfer in progress.

```
typedef struct _POPTRANSFERSTATUS
{
   UINT    nMessageId;
   DWORD   dwBytesTotal;
   DWORD   dwBytesCopied;
   DWORD   dwBytesPerSecond;
   DWORD   dwTimeElapsed;
   DWORD   dwTimeEstimated;
} POPTRANSFERSTATUS, *LPPOPTRANSFERSTATUS;
```

Members

nMessageId

The message ID of the current message that is being transferred.

dwBytesTotal

The total number of bytes that will be transferred. If the message is being copied from the server to the local host, this is the size of the message on the server. If the message is being posted to the server, it is the size of message on the local system. If the message size cannot be determined, this value will be zero.

dwBytesCopied

The total number of bytes that have been copied.

dwBytesPerSecond

The average number of bytes that have been copied per second.

dwTimeElapsed

The number of seconds that have elapsed since the transfer started.

dwTimeEstimated

The estimated number of seconds until the transfer is completed. This is based on the average number of bytes transferred per second.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SECURITYCREDENTIALS

The **SECURITYCREDENTIALS** structure specifies the information needed by the library to specify additional security credentials, such as a client certificate, when establishing a secure connection.

```
typedef struct _SECURITYCREDENTIALS
{
    DWORD    dwSize;
    DWORD    dwProtocol;
    DWORD    dwOptions;
    DWORD    dwReserved;
    LPCTSTR  lpszHostName;
    LPCTSTR  lpszUserName;
    LPCTSTR  lpszPassword;
    LPCTSTR  lpszCertStore;
    LPCTSTR  lpszCertName;
    LPCTSTR  lpszKeyFile;
} SECURITYCREDENTIALS, *LPSECURITYCREDENTIALS;
```

Members

dwSize

Size of this structure. If the structure is being allocated dynamically, this member must be set to the size of the structure and all other unused structure members must be initialized to a value of zero or NULL.

dwProtocol

A bitmask of supported security protocols. The value of this structure member is constructed by using a bitwise operator with any of the following values:

Value	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_TLS	Either the TLS 1.2 or 1.3 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers which reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing

	a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Value	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

dwReserved

This structure member is reserved for future use and should always be initialized to zero.

lpszHostName

A null-terminated string which specifies the hostname that will be used when validating the server certificate. If this member is NULL, then the server certificate will be validated against the hostname used to establish the connection.

lpszUserName

A null-terminated string which identifies the owner of client certificate. Currently this member is not used by the library and should always be initialized as a NULL pointer.

lpszPassword

A null-terminated string which specifies the password needed to access the certificate. Currently this member is only used if the CREDENTIAL_STORE_FILENAME option has been specified. If there is no password associated with the certificate, then this member should be initialized as a NULL pointer.

lpszCertStore

A null-terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A null-terminated string which specifies the name of the certificate to use. The library will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the library will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the library will return an error indicating that the certificate could not be found. If the SECURITY_PROTOCOL_SSH protocol has been specified, this member should be NULL.

lpszKeyFile

This member is not used and should always be NULL. The private key cannot be specified separately and must be associated with the certificate.

Remarks

An application only needs to create this structure if the server requires the client to provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is

specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The ***dwOptions*** member should be set to CREDENTIAL_STORE_FILENAME and the ***lpszCertStore*** member should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS #12. These certificate files typically have an extension of .pfx or .p12. Note that if a password was specified when the certificate file was created, it must be provided in the ***lpszPassword*** member or the library will be unable to access the certificate.

Note that the ***lpszUserName*** and ***lpszPassword*** members are values which are used to access the certificate store or private key file. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SECURITYINFO

The **SECURITYINFO** structure contains security related information about the connection, including the protocol, cipher suite and certificate.

```
typedef struct _SECURITYINFO
{
   DWORD        dwSize;
   DWORD        dwProtocol;
   DWORD        dwCipher;
   DWORD        dwCipherStrength;
   DWORD        dwHash;
   DWORD        dwHashStrength;
   DWORD        dwKeyExchange;
   DWORD        dwCertStatus;
   SYSTEMTIME   stCertIssued;
   SYSTEMTIME   stCertExpires;
   LPCTSTR      lpszCertIssuer;
   LPCTSTR      lpszCertSubject;
   LPCTSTR      lpszFingerprint;
} SECURITYINFO, *LPSECURITYINFO;
```

Members

dwSize

Specifies the size of the data structure. This member must always be initialized to the size of the structure in bytes prior to passing the address of this structure to the function. If this this member is not initialized, an error will be returned indicating that an invalid parameter has been passed to the function.

dwProtocol

A numeric value which specifies the security protocol selected when establishing the connection.

Value	Description
SECURITY_PROTOCOL_NONE	The connection is not secure. This value indicates a standard connection was established and all other structure members will have a value of zero.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol was selected when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol was selected when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.

SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol was selected when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol was selected when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwCipher

A numeric value which specifies the cipher that was selected when establishing the secure connection.

Value	Description
SECURITY_CIPHER_AES	The Advanced Encryption Standard cipher is a fixed block size cipher which use a key size of 128, 192 or 256 bits.
SECURITY_CIPHER_DES	The Data Encryption Standard block cipher was selected. This is a fixed key length cipher, using 56-bit keys.
SECURITY_CIPHER_DES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively providing a 168-bit length key.
SECURITY_CIPHER_DESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.
SECURITY_CIPHER_RC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40 and 128 bits, in 8-bit increments.
SECURITY_CIPHER_RC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.

dwCipherStrength

A numeric value which specifies the strength (the length of the cipher key in bits) of the cipher that was selected. Typically this value will be 128 or 256. 40-bit and 56-bit key lengths are considered weak encryption, and subject to brute force attacks. 128-bit and 256-bit key lengths are considered to be secure, and are the recommended key length for secure communications.

dwHash

A numeric value which specifies the hash algorithm which was selected.

Value	Description
SECURITY_HASH_MD5	The MD5 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA1	The SHA-1 algorithm was selected. Its use has been deprecated and is no longer considered to be

	cryptographically secure.
SECURITY_HASH_SHA256	The SHA-256 algorithm was selected.
SECURITY_HASH_SHA384	The SHA-384 algorithm was selected.
SECURITY_HASH_SHA512	The SHA-512 algorithm was selected.

dwHashStrength

A numeric value which specifies the strength (the length in bits) of the message digest that was selected.

dwKeyExchange

A numeric value which specifies the key exchange algorithm which was selected.

Value	Description
SECURITY_KEYEX_RSA	The RSA public key algorithm was selected.
SECURITY_KEYEX_KEA	The Key Exchange Algorithm (KEA) was selected. This is an improved version of the Diffie-Hellman public key algorithm.
SECURITY_KEYEX_DH	The Diffie-Hellman key exchange algorithm was selected.
SECURITY_KEYEX_ECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography.

dwCertStatus

A numeric value which specifies the status of the certificate returned by the secure server.

Value	Description
SECURITY_CERTIFICATE_VALID	The certificate is valid.
SECURITY_CERTIFICATE_NOMATCH	The certificate is valid, but the domain name does not match the common name in the certificate.
SECURITY_CERTIFICATE_EXPIRED	The certificate is valid, but has expired.
SECURITY_CERTIFICATE_REVOKED	The certificate has been revoked and is no longer valid.
SECURITY_CERTIFICATE_UNTRUSTED	The certificate or certificate authority is not trusted on the local system.
SECURITY_CERTIFICATE_INVALID	The certificate is invalid. This typically indicates that the internal structure of the certificate has been damaged.

stCertIssued

A structure which contains the date and time that the certificate was issued by the certificate authority. If the issue date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values.

stCertExpires

A structure which contains the date and time that the certificate expires. If the expiration date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values.

lpszCertIssuer

A null-terminated string which contains information about the organization that issued the certificate. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate issuer could not be determined, this member may be NULL.

lpszCertSubject

A null-terminated string which contains information about the organization that the certificate was issued to. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate subject could not be determined, this member may be NULL.

lpszFingerprint

A null-terminated string which contains a sequence of hexadecimal values that uniquely identify the server. This member may be NULL.

Remarks

The size of this structure is typically determined using the **sizeof** operator in C/C++ and most other languages have a similar method for obtaining the size of a data structure or user-defined type. It is important to note the size of this structure will be different on 32-bit and 64-bit platforms due to the difference in the length of the structure members which are pointers.

When evaluating structure members which are string pointers, such as ***lpszCertIssuer*** and ***lpszCertSubject***, you should always check to ensure their values are not NULL (zero) before attempting to dereference them. If those values are undefined, it is not guaranteed they will point to zero-length strings.

There are additional protocols and ciphers defined which are not listed above because they are considered insecure and are no longer supported. It is important to note that most servers will reject attempts to use unsupported protocols such as SSL 3.0 and will either abort the connection or issue an error message and then immediately disconnect.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

SYSTEMTIME

The **SYSTEMTIME** structure represents a date and time using individual members for the month, day, year, weekday, hour, minute, second, and millisecond.

```
typedef struct _SYSTEMTIME
{
    WORD wYear;
    WORD wMonth;
    WORD wDayOfWeek;
    WORD wDay;
    WORD wHour;
    WORD wMinute;
    WORD wSecond;
    WORD wMilliseconds;
} SYSTEMTIME, *LPSYSTEMTIME;
```

Members

wYear

Specifies the current year. The year value must be greater than 1601.

wMonth

Specifies the current month. January is 1, February is 2 and so on.

wDayOfWeek

Specifies the current day of the week. Sunday is 0, Monday is 1 and so on.

wDay

Specifies the current day of the month

wHour

Specifies the current hour.

wMinute

Specifies the current minute

wSecond

Specifies the current second.

wMilliseconds

Specifies the current millisecond.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Remote Command Protocol Class Library

Execute commands on a server or establish an interactive terminal session.

Reference

- Class Methods
- Error Codes

Library Information

Class Name	CRshClient
File Name	CSRSHV12.DLL
Version	12.0.3024.1286
LibID	BA9EA46F-9835-474A-90B1-535762F4E993
Import Library	CSRSHV12.LIB
Dependencies	None
Standards	RFC 1282

Overview

The Remote Command protocol is used to execute a command on a server and return the output of that command to the client. This is most commonly used with UNIX based servers, although there are implementations of remote command servers for the Windows operating system. The class supports both the rcmd and rshell remote execution protocols and provides methods which can be used to search the data stream for specific sequences of characters. This makes it extremely easy to write Windows applications which serve as light-weight client interfaces to commands being executed on a UNIX server or another Windows system. The library can also be used to establish a remote terminal session using the rlogin protocol, which is similar to the Telnet protocol.

The Remote Shell (rsh/rcmd) protocol is deprecated, insecure, and should never be used. This protocol transmits user credentials and command data in plaintext, making it vulnerable to interception, spoofing, and other network-based attacks. Support for this protocol will be removed in a future release. For secure remote command execution and interactive terminal sessions, it is recommended you use the Secure Shell class.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). You should install all updates for your development tools and have the current Windows SDK installed. The minimum supported version of Visual Studio is Visual Studio 2010 with Service Pack 1 (SP1) installed. The SocketTools header files are designed to be compatible with all modern C/C++ compilers and we also provide function definitions for several additional languages such as Object Pascal and Visual Basic.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are deploying applications to Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. If you are deploying applications to Windows 8, you must have the 8.1 update installed. If you are targeting the Windows on ARM platform, the minimum

required version is Windows 10 build 1709.

SocketTools includes support for both 64-bit and 32-bit Windows platforms. All current versions of Windows are 64-bit, and we include 32-bit x86 libraries to maintain compatibility with legacy development tools. SocketTools also provides native ARM64 libraries for systems running Windows on ARM. Note that 32-bit applications on ARM use x86 emulation, and Microsoft no longer supports native 32-bit ARM (ARM32) applications. Embarcadero's C++Builder and Delphi compilers (as of version 12.3) do not support building native ARM64 applications for Windows. For developing applications targeting the Windows on ARM platform, we recommend using Visual Studio 2019 or later.

The import libraries included with SocketTools are provided in several different formats. The most commonly used format is COFF, which is available for x64, x86 and native ARM64 platforms. For compatibility with older Borland (Embarcadero) compilers, we also provide OMF libraries for x86 platforms and ELF libraries for x64 platforms. If you are using Visual Studio, you will want to use the standard COFF import libraries. Note that some languages may not require import libraries and will link to the exported functions in the DLL based on the function declaration itself.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Remote Command Protocol Class Methods

Class	Description
CRshClient	Constructor which initializes the current instance of the class
~CRshClient	Destructor which releases resources allocated by the class
Method	Description
AttachHandle	Attach the specified client handle to this instance of the class
AttachThread	Attach the specified client handle to another thread
Cancel	Cancel the current blocking operation
DetachHandle	Detach the handle for the current instance of this class
DisableEvents	Disable asynchronous event notification
DisableTrace	Disable logging of network function calls
Disconnect	Disconnect from the current server
EnableEvents	Enable asynchronous event notification
EnableTrace	Enable logging of network function calls to a file
Execute	Execute a command on the server
FreezeEvents	Suspend asynchronous event processing
GetErrorString	Return a description for the specified error code
GetHandle	Return the client handle used by this instance of the class
GetLastError	Return the last error code
GetStatus	Return the current client status
GetTimeout	Return the number of seconds until an operation times out
IsBlocking	Determine if the client is blocked, waiting for information
IsConnected	Determine if the client is connected to the server
IsInitialized	Determine if the class has been successfully initialized
IsReadable	Determine if data can be read from the server
IsWritable	Determine if data can be written to the server
Login	Establish a login session with the specified server
Read	Read data returned by the server
RegisterEvent	Register an event callback function
RshEventProc	Callback method that processes events generated by the client
Search	Search for a specific character sequence in the data stream
SetLastError	Set the last error code
SetTimeout	Set the number of seconds until an operation times out
ShowError	Display a message box with a description of the specified error

Write	Write data to the server

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CRshClient::CRshClient

```
CRshClient();
```

The **CRshClient** constructor initializes the class library and validates the license key at runtime.

The Remote Shell (rsh/rcmd) protocol is deprecated, insecure, and should never be used. This protocol transmits user credentials and command data in plaintext, making it vulnerable to interception, spoofing, and other network-based attacks. Support for this protocol will be removed in a future release. For secure remote command execution and interactive terminal sessions, it is recommended you use the Secure Shell class.

Remarks

If the constructor fails to validate the runtime license, subsequent methods in this class will fail. If the product is installed with an evaluation license, then the application will only function on the development system and cannot be redistributed.

The constructor calls the **RshInitialize** function to initialize the library, which dynamically loads other system libraries and allocates thread local storage. If you are using this class within another DLL, it is important that you do not create or destroy an instance of the class from within the **DllMain** function because it can result in deadlocks or access violation errors. You should not declare static or global instances of this class within another DLL if it is linked with the C runtime library (CRT) because it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

~CRshClient, IsInitialized

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CRshClient::~CRshClient

```
~CRshClient();
```

The **CRshClient** destructor releases resources allocated by the current instance of the **CRshClient** object. It also uninitializes the library if there are no other concurrent uses of the class.

Remarks

When a **CRshClient** object goes out of scope, the destructor is automatically called to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all handles that were created for the client session are destroyed.

The destructor is not called explicitly by the application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CRshClient

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CRshClient::AttachHandle

```
VOID AttachHandle(
   HCLIENT hClient
);
```

The **AttachHandle** method attaches the specified client handle to the current instance of the class.

Parameters

hClient

The handle to the client session that will be attached to the current instance of the class object.

Return Value

None.

Remarks

This method is used to attach a client handle created outside of the class using the SocketTools API. Once the client handle is attached to the class, the other class member functions may be used with that client session.

If a client handle has already been created for the class, that handle will be released when the new handle is attached to the class object. If you want to prevent the previous client session from being terminated, you must call the **DetachHandle** method. Failure to release the detached handle may result in a resource leak in your application.

Note that the ***hClient*** parameter is presumed to be a valid client handle and no checks are performed to ensure that the handle is valid. Specifying an invalid client handle will cause subsequent method calls to fail.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib

See Also

AttachThread, DetachHandle, GetHandle

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CRshClient::AttachThread

```
DWORD AttachThread(
   DWORD dwThreadId
);
```

The **AttachThread** method attaches the specified client handle to another thread.

Parameters

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the method succeeds, the return value is the thread ID of the previous owner. If the method fails, the return value is RSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

When a client handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in a client application to create the client handle, and then pass that handle to another worker thread. The **AttachThread** method can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the method, the original owner of the handle can be restored before the worker thread terminates.

This method should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **AttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **Cancel** method and then release the handle after the blocking method exits and control is returned to the current thread.

Note that the ***dwThreadId*** parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the client handle used by the class until the destructor is called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib

See Also

AttachHandle, Cancel, DetachHandle, Disconnect, Execute, GetHandle, Login

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CRshClient::Cancel

```
INT Cancel();
```

The **Cancel** method cancels any outstanding blocking operation in the client, causing the blocking method to fail. The application may then retry the operation or terminate the client session.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is RSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

When the **Cancel** method is called, the blocking method will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib

See Also

IsBlocking

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CRshClient::DetachHandle

```
HCLIENT DetachHandle();
```

The **DetachHandle** method detaches the client handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the client handle associated with the current instance of the class object. If there is no active client session, the value INVALID_CLIENT will be returned.

Remarks

This method is used to detach a client handle created by the class for use with the SocketTools API. Once the client handle is detached from the class, no other class member functions may be called. Note that the handle must be explicitly released at some later point by the process or a resource leak will occur.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib

See Also

AttachHandle, GetHandle

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CRshClient::DisableEvents

```
INT DisableEvents();
```

The **DisableEvents** method disables the event notification mechanism, preventing subsequent event notification messages from being posted to the application's message queue.

This method has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is RSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **DisableEvents** method is used to disable event message posting for the specified client session. Although this will immediately prevent any new events from being generated, it is possible that messages could be waiting in the message queue. Therefore, an application must be prepared to handle client event messages after this method has been called.

This method is automatically called if the client has event notification enabled, and the **Disconnect** method is called. The same issues regarding outstanding event messages also applies in this situation, requiring that the application handle event messages that may reference a client handle that is no longer valid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib

See Also

EnableEvents, RegisterEvent

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CRshClient::DisableTrace

```
BOOL DisableTrace();
```

The **DisableTrace** method disables the logging of network function calls.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, a value of zero is returned.

Remarks

This method will disable output to the log file for the current thread or process, depending on the flags used when logging was enabled. If this method is not called, the resources that were allocated for the logging session will be released when the process ends.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib

See Also

EnableTrace

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CRshClient::Disconnect

```
VOID Disconnect();
```

The **Disconnect** method terminates the connection with the server, closing the socket and releasing the memory allocated for the client session.

Parameters

None.

Return Value

None.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

CRshClient::EnableEvents

```
INT EnableEvents(
   HWND hEventWnd,
   UINT uEventMsg
);
```

The **EnableEvents** method enables event notifications using Windows messages.

This method has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Applications should use the **RegisterEvent** method to register an event handler which is invoked when an event occurs.

Parameters

hEventWnd

Handle to the window which will receive the client notification messages. This parameter must specify a valid window handle. If a NULL handle is specified, event notification will be disabled.

uEventMsg

The message that is received when a client event occurs. This value must be greater than 1024.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is RSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **EnableEvents** method is used to request that notification messages be posted to the specified window whenever a client event occurs. This allows an application to monitor the status of different client operations, such as a file transfer.

The *wParam* argument will contain the client handle, the low word of the *lParam* argument will contain the event ID, and the high word will contain any error code. If no error has occurred, the high word will always have a value of zero. The following events may be generated:

Value	Description
RSH_EVENT_CONNECT	The connection to the server has completed. The high word of the *lParam* parameter should be checked, since this notification message will be posted if an error has occurred.
RSH_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
RSH_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
RSH_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This

	event is only generated if the client is in asynchronous mode.
RSH_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
RSH_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

To disable event notification, call the **DisableEvents** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib

CRshClient::EnableTrace

```
BOOL EnableTrace(
   LPCTSTR lpszTraceFile,
   DWORD dwTraceFlags
);
```

The **EnableTrace** method enables the logging of network function calls to a file.

Parameters

lpszTraceFile

A null-terminated string which specifies the name of the logfile which will be appended to or created. It is recommended that this file always specify an absolute path to avoid any ambiguity. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
TRACE_INFO	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
TRACE_ERROR	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
TRACE_HEXDUMP	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
TRACE_TRUNCATE	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for

	multithreaded applications that are using worker threads.

Return Value

If the method succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the log file cannot be created.

Remarks

Logging is enabled and disabled at the thread or process level, depending on the flags passed to this method, and is not associated with a specific class instance. When logging is enabled, the information is appended to the specified file. If the file does not exist, it will be created. To limit the size of the file, enable and disable logging only around those sections of code that you wish to debug. If you do not provide a full path to the file, it will be relative to the current working directory for the process. This can produce unexpected results in multithreaded applications because the current directory is global to the entire process and can be changed by any thread at any time.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

The TRACE_HEXDUMP option can generate very large files because it includes all of the data exchanged between your application and the remote host. The TRACE_TRUNCATE option is only evaluated when logging is first enabled for a thread or process. If logging is already active, specifying this option will have no effect.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "**0x**". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxxx:xxxx::xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, a connection is being made to a system with the IPv4 address 192.0.0.1 on port 1234.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib
Unicode: Implemented as Unicode and ANSI versions

CRshClient::Execute

```
BOOL Execute(
   LPCTSTR lpszRemoteHost,
   LPCTSTR lpszUserName,
   LPCTSTR lpszPassword,
   LPCTSTR lpszCommand,
   UINT nRemotePort,
   UINT nTimeout,
   DWORD dwOptions
);

BOOL Execute(
   LPCTSTR lpszRemoteHost,
   LPCTSTR lpszUserName,
   LPCTSTR lpszCommand,
   UINT nRemotePort,
   UINT nTimeout,
   DWORD dwOptions
);
```

The **Execute** method is used to establish a connection with the server and execute the specified command.

Parameters

lpszRemoteHost

The name of the server to connect to; this may be a fully-qualified domain name or an IP address.

lpszUserName

A null-terminated string which specifies the username used to authenticate the client session.

lpszPassword

A null-terminated string which specifies the password used to authenticate the client session.

lpszCommand

A null-terminated string which specifies the command to execute on the server.

nRemotePort

The port number the server is listening on. One of the following values should be used:

Value	Description
RSH_PORT_REXEC	A connection is established with the server using port 512, the rexec service. This service requires that the client provide a username and password to execute the specified command. This is the default port used when calling the version of the method which specifies a password.
RSH_PORT_RSHELL	A connection is established with the server using port 514, the rshell service. This service uses host equivalence to authenticate the user. With host equivalence, the server considers the client to be equivalent to itself, and as long as the specified user exists on the server, the client is permitted to execute commands on behalf of the user without requiring a password. Host equivalence is configured by the server administrator. This is the default port used when calling the

	version of the method that does not specify a password.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
RSH_OPTION_RESERVEDPORT	This option specifies that a reserved port should be used to establish the connection. Reserved ports are those port numbers which are less than 1024. This option should be specified when connecting on the RSH_PORT_RSHELL port.
RSH_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
RSH_OPTION_FREETHREAD	This option specifies that this instance of the class may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the class instance is synchronized across multiple threads.

Return Value

If the method succeeds, the return value non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method will block the current thread until a connection has been established or the timeout period has elapsed. To prevent it from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling the **Connect** method in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each connection.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the class instance is initially attached to the thread that created it. From that point on, until the handle is released, only the owner may call methods using that instance of the class. The ownership of the class instance may be transferred from one thread to another using the **AttachThread** method.

Specifying the POP_OPTION_FREETHREAD option enables any thread to call any method in that instance of the class, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the class instance is synchronized. If one thread calls a function

in the library, it must ensure that no other thread will call another function at the same time using the same instance.

Example

The following example demonstrates connecting to a server, executing a command on the server, reading the output and storing it in a string. This uses the rexec service on port 512, and requires a username and password.

```
CRshClient rshClient;
BOOL bConnected;

// Establish a connection with the server and execute
// the command as the specified user
bConnected = rshClient.Execute(strHostName,
                               strUserName,
                               strPassword,
                               strCommand);

// If the connection could not be established or the command
// could not be executed, display an error message
if (bConnected == FALSE)
{
    rshClient.ShowError();
    return;
}

CString strBuffer;
CString strResult;
INT nResult;

// Read the output from the command and store it in the strResult
// string; note that a UNIX server terminates each line of output
// with a bare linefeed, which is something that should be kept
// in mind when parsing the string
do
{
    if ((nResult = rshClient.Read(strBuffer)) > 0)
        strResult += strBuffer;
}
while (nResult > 0);

// If there was an error reading the output from the server, then
// display the error and disconnect
if (nResult == RSH_ERROR)
{
    rshClient.ShowError();
    rshClient.Disconnect();
    return;
}

rshClient.Disconnect();
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib

Unicode: Implemented as Unicode and ANSI versions

CRshClient::FreezeEvents

```
INT FreezeEvents(
   BOOL bFreeze
);
```

The **FreezeEvents** method is used to suspend and resume event handling by the client.

Parameters

bFreeze

A non-zero value specifies that event handling should be suspended by the client. A zero value specifies that event handling should be resumed.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is RSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

This method should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all client events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if the client has suspended event handling, and four read events occur, once event handling is resumed only one of those read events will be posted to the client. This prevents the application from being flooded by a potentially large number of queued events.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib
Unicode: Implemented as Unicode and ANSI versions

CRshClient::GetErrorString

```
INT GetErrorString(
   DWORD dwErrorCode,
   LPTSTR lpszDescription,
   INT nMaxLength
);

INT GetErrorString(
   DWORD dwErrorCode,
   CString& strDescription
);
```

The **GetErrorString** method is used to return a description of a specific error code. Typically this is used in conjunction with the **GetLastError** method for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

The buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length. An alternate form of the method accepts a **CString** variable which will contain the error description.

nMaxLength

The maximum number of characters that may be copied into the description buffer.

Return Value

If the method succeeds, the return value is the length of the description string. If the method fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the method is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CRshClient::GetHandle

```
HCLIENT GetHandle();
```

The **GetHandle** method returns the client handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the client handle associated with the current instance of the class object. If there is no active client session, the value INVALID_CLIENT will be returned.

Remarks

This method is used to obtain the client handle created by the class for use with the SocketTools API.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib

CRshClient::GetLastError

```
DWORD GetLastError();

DWORD GetLastError(
   CString& strDescription
);
```

Parameters

strDescription

A string which will contain a description of the last error code value when the method returns. If no error has been set, or the last error code has been cleared, this string will be empty.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **SetLastError** method. The Return Value section of each reference page notes the conditions under which the method sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **GetLastError** method immediately when a method's return value indicates that an error has occurred. That is because some methods call **SetLastError**(0) when they succeed, clearing the error code set by the most recently failed method.

Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or RSH_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

The description of the error code is the same string that is returned by the **GetErrorString** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib

See Also

GetErrorString, SetLastError, ShowError

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CRshClient::GetStatus

```
INT GetStatus();
```

The **GetStatus** method the current status of the client session.

Parameters

None.

Return Value

If the method succeeds, the return value is the client status code. If the method fails, the return value is RSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetStatus** method returns a numeric code which identifies the current state of the client session. The following values may be returned:

Value	Description
RSH_STATUS_UNUSED	No connection has been established.
RSH_STATUS_IDLE	The client is current idle and not sending or receiving data.
RSH_STATUS_CONNECT	The client is establishing a connection with the server.
RSH_STATUS_READ	The client is reading data from the server.
RSH_STATUS_WRITE	The client is writing data to the server.
RSH_STATUS_DISCONNECT	The client is disconnecting from the server.

In a multithreaded application, any thread in the current process may call this method to obtain status information for the specified client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib

See Also

IsBlocking, IsConnected, IsReadable

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CRshClient::GetTimeout

```
INT GetTimeout();
```

The **GetTimeout** method returns the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the method will fail and return to the caller.

Parameters

None.

Return Value

If the method succeeds, the return value is the timeout period in seconds. If the method fails, the return value is RSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

The timeout value is only used with blocking client connections. A value of zero indicates that the default timeout period of 20 seconds should be used.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib

See Also

IsReadable, IsWritable, Read, SetTimeout, Write

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CRshClient::IsBlocking

```
BOOL IsBlocking();
```

The **IsBlocking** method is used to determine if the client is currently performing a blocking operation.

Parameters

None.

Return Value

If the client is performing a blocking operation, the method returns a non-zero value. If the client is not performing a blocking operation, or the client handle is invalid, the method returns zero.

Remarks

Because a blocking operation can allow the application to be re-entered (for example, by pressing a button while the operation is being performed), it is possible that another blocking method may be called while it is in progress. Since only one thread of execution may perform a blocking operation at any one time, an error would occur. The **IsBlocking** method can be used to determine if the client is already blocked, and if so, take some other action (such as warning the user that they must wait for the operation to complete).

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

Cancel, GetStatus, IsConnected, IsInitialized, IsReadable, IsWritable, Read, Write

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CRshClient::IsConnected

```
BOOL IsConnected();
```

The **IsConnected** method is used to determine if the client is currently connected to a server.

Parameters

None.

Return Value

If the client is connected to a server, the method returns a non-zero value. If the client is not connected, or the client handle is invalid, the method returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib

See Also

GetStatus, IsBlocking, IsInitialized, IsReadable, IsWritable

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CRshClient::IsInitialized

```
BOOL IsInitialized();
```

The **IsInitialized** method returns whether or not the class object has been successfully initialized.

Parameters

None.

Return Value

This method returns a non-zero value if the class object has been successfully initialized. A return value of zero indicates that the runtime license key could not be validated or the networking library could not be loaded by the current process.

Remarks

When an instance of the class is created, the class constructor will attempt to initialize the component with the runtime license key that was created when SocketTools was installed. If the constructor is unable to validate the license key or load the networking libraries, this initialization will fail.

If SocketTools was installed with an evaluation license, the application cannot be redistributed to another system. The class object will fail to initialize if the application is executed on another system, or if the evaluation period has expired. To redistribute your application, you must purchase a development license which will include the runtime key that is needed to redistribute your software to other systems. Refer to the Developer's Guide for more information.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib

See Also

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CRshClient::IsReadable

```
BOOL IsReadable(
   INT nTimeout,
   LPDWORD lpdwAvail
);
```

The **IsReadable** method is used to determine if data is available to be read from the server.

Parameters

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

lpdwAvail

A pointer to an unsigned integer which will contain the number of bytes available to read. This parameter may be NULL if this information is not required.

Return Value

If the client can read data from the server within the specified timeout period, the method returns a non-zero value. If the client cannot read any data, the method returns zero.

Remarks

On some platforms, this value will not exceed the size of the receive buffer (typically 64K bytes). Because of differences between TCP/IP stack implementations, it is not recommended that your application exclusively depend on this value to determine the exact number of bytes available. Instead, it should be used as a general indicator that there is data available to be read.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib

See Also

GetStatus, IsBlocking, IsConnected, IsInitialized, IsWritable, Write

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CRshClient::IsWritable

```
BOOL IsWritable(
   INT nTimeout
);
```

The **IsWritable** method is used to determine if data can be written to the server.

Parameters

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

Return Value

If the client can write data to the server within the specified timeout period, the method returns a non-zero value. If the client cannot write any data, the method returns zero.

Remarks

Although this method can be used to determine if some amount of data can be sent to the remote process it does not indicate the amount of data that can be written without blocking the client. In most cases, it is recommended that large amounts of data be broken into smaller logical blocks, typically some multiple of 512 bytes in length.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib

See Also

GetStatus, IsBlocking, IsConnected, IsInitialized, IsReadable, Write

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CRshClient::Login

```
BOOL Login(
   LPCTSTR lpszRemoteHost,
   LPCTSTR lpszUserName,
   LPCTSTR lpszTerminal,
   UINT nRemotePort,
   UINT nTimeout
);
```

The **Login** method is used to establish a connection with the server.

Parameters

lpszRemoteHost

The name of the server to connect to; this may be a fully-qualified domain name or an IP address.

lpszUserName

A null-terminated string which specifies the username used to authenticate the client session.

lpszTerminal

A null-terminated string which specifies the terminal type which the client will be identified as using during the session. If no particular terminal emulation is required, this parameter may be NULL.

nRemotePort

The port number the server is listening on. A value of zero specifies that the default port of 513 should be used.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method uses host equivalence, where the client is permitted to login without requiring a password. Host equivalence must be configured by the server administrator and it is typically restricted to specific users. Note that if configured improperly, host equivalence can introduce a significant security loophole. Refer to your UNIX system documentation for more information about host equivalence and the various remote command services.

On UNIX based systems, the terminal name specified by the ***lpszTerminal*** parameter corresponds to a termcap or terminfo entry as set in the TERM environment variable. On Windows based systems which implement the rlogin service, this parameter may be ignored and the server will assume that the client is capable of displaying ANSI escape sequences. On VMS systems, the terminal name should correspond to the terminal type used with the SET TERMINAL/DEVICE command.

If this parameter is passed as NULL pointer or an empty string, a default terminal type named "unknown" will be used. On most UNIX and VMS systems this defines a terminal which is not capable of cursor positioning using control or escape sequences. This terminal type may not be recognized and an error may be displayed when the user logs in indicating that the terminal type is invalid.

Refer to the documentation for the server system to determine what terminal type names are available

to you. Remember that on UNIX systems, the terminal type is case-sensitive. Some of the more common terminal types are:

Terminal Type	Description
ansi	This terminal type is usually available on UNIX based servers. This specifies that the client is capable of displaying standard ANSI escape sequences for cursor control.
dumb	This terminal type typically specifies a terminal display which does not support control or escape sequences for cursor positioning. If you do not want escape sequences embedded in the data stream and the server returns an error if the terminal type is not specified, try using this terminal type.
pcansi	This terminal type is usually available on UNIX based servers. This specifies that the client is a using a PC terminal emulator that supports basic ANSI escape sequences for cursor control. This may also enable escape sequences which can set the display colors.
vt100	This terminal type is usually available on UNIX and VMS based servers. On some VMS systems this string may need to be specified as DEC-VT100. This specifies that the client is capable of emulating a DEC VT100 terminal. The VT100 supports many of the same cursor control sequences as an ANSI terminal.
vt220	This terminal type is usually available on UNIX and VMS based servers. On some VMS systems this string may need to be specified as DEC-VT220. This specifies that the client is capable of emulating a DEC VT220 terminal, which is a later version of the VT100.
vt320	This terminal type is usually available on UNIX and VMS based servers. On some VMS systems this string may need to be specified as DEC-VT320. This specifies that the client is capable of emulating a DEC VT320 terminal, which is similar to the VT100 and VT220 and provides advanced features such as the ability to set display colors.
xterm	This terminal type is may be available on UNIX based servers which have X Windows installed. This specifies that the client is a using the X Windows xterm emulator which supports standard ANSI escape sequences for cursor control.

This method will block the current thread until a connection has been established or the timeout period has elapsed. To prevent it from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling the **Connect** method in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each connection.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

Disconnect, Execute

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CRshClient::Read

```
INT Read(
   LPBYTE lpBuffer,
   INT cbBuffer
);

INT Read(
   CString& strBuffer,
   INT cbBuffer
);
```

The **Read** method reads the specified number of bytes from the client socket and copies them into the buffer. The data may be of any type, and is not terminated with a null character.

Parameters

lpBuffer

Pointer to the buffer in which the data will be copied. An alternate form of this method allows a **CString** variable to be passed and data read from the socket will be returned in that string.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

Return Value

If the method succeeds, the return value is the number of bytes actually read. A return value of zero indicates that the server has closed the connection and there is no more data available to be read. If the method fails, the return value is RSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

When **Read** is called and the client is in non-blocking mode, it is possible that the method will fail because there is no available data to read at that time. This should not be considered a fatal error. Instead, the application should simply wait to receive the next asynchronous notification that data is available.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib

See Also

EnableEvents, IsBlocking, IsReadable, IsWritable, RegisterEvent, Write

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CRshClient::RegisterEvent

```
INT RegisterEvent(
   UINT nEventId,
   RSHEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

The **RegisterEvent** method registers an event handler for the specified event.

Parameters

nEventId

An unsigned integer which specifies which event should be registered with the specified callback function. One of the following values may be used:

Value	Description
RSH_EVENT_CONNECT	The connection to the server has completed.
RSH_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
RSH_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
RSH_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
RSH_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
RSH_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **RshEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is RSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **RegisterEvent** method associates a callback function with a specific event. The event handler is an **RshEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

The callback function specified by the ***lpEventProc*** parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

The ***dwParam*** parameter is commonly used to identify the class instance which is associated with the event that has occurred. Applications will cast the **this** pointer to a DWORD_PTR value when calling this function, and then the event handler will cast it back to a pointer to the class instance. This gives the handler access to the class member variables and methods.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib

CRshClient::Search

```
BOOL Search(
   LPCTSTR lpszString
);

BOOL Search(
   LPCTSTR lpszString,
   LPVOID lpBuffer,
   LPDWORD lpdwLength
);

BOOL Search(
   LPCTSTR lpszString,
   HGLOBAL *lpBuffer,
   LPDWORD lpdwLength
);

BOOL Search(
   LPCTSTR lpszString,
   CString& strBuffer
);
```

The **Search** method searches for a specific character sequence in the data stream and stops reading if the sequence is encountered.

Parameters

lpszString

A null-terminated string which specifies the sequence of characters to search for in the data stream. This parameter cannot be NULL or point to an empty string.

lpBuffer

A buffer which will contain the output from the server, or a pointer to a global memory handle which will reference the output when the method returns. An alternate form of this method accepts a **CString** object which will contain the output when the method returns. If the output from the server is not required, this parameter may be NULL.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the ***lpBuffer*** parameter. If the ***lpBuffer*** parameter points to a global memory handle, the length value should be initialized to zero. When the method returns, this value will be updated with the actual number of bytes of output stored in the buffer. If the ***lpBuffer*** parameter is NULL, this parameter should also be NULL.

Return Value

If the method succeeds and the character sequences was found in the data stream, the return value is non-zero. If the method fails or a timeout occurs before the sequence is found, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **Search** method searches for a character sequence in the data stream and stops reading when it is found. This is useful when the client wants to automate responses to the server, such as executing a command and processing the output. The method collects the output from the server and stores it in the buffer specified by the ***lpBuffer*** parameter. When the method returns, the buffer will contain

everything sent by the server up to and including the search string.

The ***lpBuffer*** parameter may be specified in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the a fixed amount of output. In this case, the ***lpBuffer*** parameter will point to the buffer that was allocated, the value that the ***lpdwLength*** parameter points to should be initialized to the size of that buffer. If the server sends more output than can be stored in the buffer, the remaining output will be discarded.

The second method that can be used is have the ***lpBuffer*** parameter point to a global memory handle which will contain the output when the method returns. In this case, the value that the ***lpdwLength*** parameter points to must be initialized to zero. It is important to note that the memory handle returned by the method must be freed by the application, otherwise a memory leak will occur. This method is preferred if the client application does not have a general idea of how much output will be generated until the search string is found.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

Execute, IsBlocking, IsReadable, Login, Read

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CRshClient::SetLastError

```
VOID SetLastError(
   DWORD dwErrorCode
);
```

The **SetLastError** method sets the last error code for the current thread. This method is typically used to clear the last error by specifying a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or RSH_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

Applications can retrieve the value saved by this method by using the **GetLastError** method. The use of **GetLastError** is optional; an application can call the method to determine the specific reason for a method failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib

GetErrorString, GetLastError, ShowError

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CRshClient::SetTimeout

```
INT SetTimeout(
   UINT nTimeout
);
```

The **SetTimeout** method sets the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the method will fail and return to the caller.

Parameters

nTimeout

The number of seconds to wait for a blocking operation to complete.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is RSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

The timeout value is only used with blocking client connections.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib

See Also

CRshClient::ShowError

```
INT ShowError(
   LPCTSTR lpszAppTitle,
   UINT uType,
   DWORD dwErrorCode
);
```

The **ShowError** method displays a message box which describes the specified error.

Parameters

lpszAppTitle

A null-terminated string which specifies the title of the message box that is displayed. If this argument is NULL or omitted, then the default title of "Error" will be displayed.

uType

An unsigned integer which specifies the type of message box that will be displayed. This is the same value that is used by the **MessageBox** method in the Windows API. If a value of zero is specified, then a message box with a single OK button will be displayed. Refer to that method for a complete list of options.

dwErrorCode

Specifies the error code that will be used when displaying the message box. If this argument is zero, then the last error that occurred in the current thread will be displayed.

Return Value

If the method is successful, the return value will be the return value from the **MessageBox** function. If the method fails, it will return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib
Unicode: Implemented as Unicode and ANSI versions

CRshClient::Write

```
INT Write(
   LPBYTE lpBuffer,
   INT cbBuffer
);

INT Write(
   LPCTSTR lpszBuffer
   INT cbBuffer
);
```

The **Write** method sends the specified number of bytes to the server.

Parameters

lpBuffer

The pointer to the buffer which contains the data that is to be sent to the server. In an alternate form of the method, the pointer is to a string.

cbBuffer

The number of bytes to send from the specified buffer. This value must be greater than zero, unless a pointer to a string buffer is passed as the parameter. In that case, if the value is -1, all of the characters in the string, up to but not including the terminating null character, will be sent to the server.

Return Value

If the method succeeds, the return value is the number of bytes actually written. If the method fails, the return value is RSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

The return value may be less than the number of bytes specified by the ***cbBuffer*** parameter. In this case, the data has been partially written and it is the responsibility of the client application to send the remaining data at some later point. For non-blocking clients, the client must wait for the next asynchronous notification message before it resumes sending data.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib

Secure Shell Protocol Class Library

Establish an interactive terminal session with an SSH server and execute remote commands.

Reference

- Class Methods
- Data Structures
- Error Codes

Library Information

Class Name	CSshClient
File Name	CSTSHV12.DLL
Version	12.0.3024.1286
LibID	758D7F52-CE33-4C44-B404-EBF1F15875E8
Import Library	CSTSHV12.LIB
Dependencies	None
Standards	RFC 4251

Overview

The Secure Shell (SSH) protocol is used to establish a secure connection with a server which provides a virtual terminal session for a user. Its functionality is similar to how character based consoles and serial terminals work, enabling a user to login to the server, execute commands and interact with applications running on the server. The SshClient class provides an API for establishing the connection and handling the standard I/O functions needed by the program.

Standard password and private key authentication methods are supported. The class will automatically select the strongest cipher suite available to both the client and server, providing support for AES-256 encryption and elliptical curve key exchance algorithms like ECDH and Curve25519. The control also supports some legacy algortithms for backwards compatibility with older servers but will only use them if no other options are available. If the server you are connecting with is based on OpenSSH, we recommend using OpenSSH 7.0 or later. Earlier versions of OpenSSH may request the use of encryption algorithms which are no longer considered secure.

The class also provides methods which enable a program to easily scan the data stream for specific sequences of characters, making it very simple to write lightweight client interfaces to applications running on the server. This class can be combined with the CTerminalEmulator class to provide terminal emulation services for a standard ANSI or DEC-VT220 terminal.

Important: The Secure Shell (SSH) API provides a secure, encrypted alternative to legacy protocols such as Remote Shell (rsh/rcmd), Remote Login (rlogin), and Telnet. Unlike those older protocols, SSH uses strong authentication and end-to-end encryption to protect user credentials, command input, and output data from interception or tampering. SSH is the recommended protocol for remote command execution and interactive terminal sessions, particularly when connecting over public or untrusted networks. It ensures confidentiality and integrity of data in transit, and is widely supported on modern operating systems and network infrastructure. If you are currently using Telnet or Remote Shell in your applications, you are strongly encouraged to migrate to the Secure Shell API. These older

protocols are inherently insecure and should not be used in any context where data security matters.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). You should install all updates for your development tools and have the current Windows SDK installed. The minimum supported version of Visual Studio is Visual Studio 2010 with Service Pack 1 (SP1) installed. The SocketTools header files are designed to be compatible with all modern C/C++ compilers and we also provide function definitions for several additional languages such as Object Pascal and Visual Basic.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are deploying applications to Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. If you are deploying applications to Windows 8, you must have the 8.1 update installed. If you are targeting the Windows on ARM platform, the minimum required version is Windows 10 build 1709.

SocketTools includes support for both 64-bit and 32-bit Windows platforms. All current versions of Windows are 64-bit, and we include 32-bit x86 libraries to maintain compatibility with legacy development tools. SocketTools also provides native ARM64 libraries for systems running Windows on ARM. Note that 32-bit applications on ARM use x86 emulation, and Microsoft no longer supports native 32-bit ARM (ARM32) applications. Embarcadero's C++Builder and Delphi compilers (as of version 12.3) do not support building native ARM64 applications for Windows. For developing applications targeting the Windows on ARM platform, we recommend using Visual Studio 2019 or later.

The import libraries included with SocketTools are provided in several different formats. The most commonly used format is COFF, which is available for x64, x86 and native ARM64 platforms. For compatibility with older Borland (Embarcadero) compilers, we also provide OMF libraries for x86 platforms and ELF libraries for x64 platforms. If you are using Visual Studio, you will want to use the standard COFF import libraries. Note that some languages may not require import libraries and will link to the exported functions in the DLL based on the function declaration itself.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

SSH Protocol Class Methods

Class	Description
CSshClient	Constructor which initializes the current instance of the class
~CSshClient	Destructor which releases resources allocated by the class
Method	Description
AttachHandle	Attach the specified client handle to this instance of the class
AttachThread	Attach the specified client handle to another thread
Break	Send a break signal to the server
Cancel	Cancel the current blocking operation
Connect	Connect to the specified server
Control	Send a control message to the server
CreateSecurityCredentials	Create a new security credentials structure
DeleteSecurityCredentials	Delete a previously created security credentials structure
DetachHandle	Detach the handle for the current instance of this class
DisableEvents	Disable asynchronous event notification
DisableTrace	Disable logging of network function calls
Disconnect	Disconnect from the current server
EnableEvents	Enable asynchronous event notification
EnableTrace	Enable logging of network function calls to a file
Execute	Execute a command on a server and return the output in the specified buffer
FreezeEvents	Suspend asynchronous event processing
GetErrorString	Return a description for the specified error code
GetExitCode	Return the exit code for the remote session
GetHandle	Return the client handle used by this instance of the class
GetLastError	Return the last error code
GetLineMode	Return the current mode used to send end-of-line character sequences
GetSecurityInformation	Return security information about the current client connection
GetStatus	Return the current client status
GetTimeout	Return the number of seconds until an operation times out
IsBlocking	Determine if the client is blocked, waiting for information
IsConnected	Determine if the client is connected to the server
IsInitialized	Determine if the class has been successfully initialized
IsReadable	Determine if data can be read from the server
IsWritable	Determine if data can be written to the server

Peek	Examine data in the receive buffer, but do not remove it
Read	Read data returned by the server
ReadLine	Read a line of data from the server and return it in a string buffer
RegisterEvent	Register an event callback function
Search	Search for a specific character sequence in the data stream
SetLastError	Set the last error code
SetLineMode	Change how end-of-line character sequences are sent to the server
SetTimeout	Set the number of seconds until an operation times out
ShowError	Display a message box with a description of the specified error
SshEventProc	Callback function that processes events generated by the client
Write	Write data to the server
WriteLine	Write a line of data to the server

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSshClient::CSshClient Method

```
CSshClient();
```

The **CSshClient** constructor initializes the class library and validates the license key at runtime.

Remarks

If the constructor fails to validate the runtime license, subsequent methods in this class will fail. If the product is installed with an evaluation license, then the application will only function on the development system and cannot be redistributed.

The constructor calls the **SshInitialize** function to initialize the library, which dynamically loads other system libraries and allocates thread local storage. If you are using this class within another DLL, it is important that you do not create or destroy an instance of the class from within the **DllMain** function because it can result in deadlocks or access violation errors. You should not declare static or global instances of this class within another DLL if it is linked with the C runtime library (CRT) because it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

~CSshClient, IsInitialized

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSshClient::~CSshClient

```
~CSshClient();
```

The **CSshClient** destructor releases resources allocated by the current instance of the **CSshClient** object. It also uninitializes the library if there are no other concurrent uses of the class.

Remarks

When a **CSshClient** object goes out of scope, the destructor is automatically called to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all handles that were created for the client session are destroyed.

The destructor is not called explicitly by the application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CSshClient

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSshClient::AttachHandle Method

```
VOID AttachHandle(
   HCLIENT hClient
);
```

The **AttachHandle** method attaches the specified client handle to the current instance of the class.

Parameters

hClient

The handle to the client session that will be attached to the current instance of the class object.

Return Value

None.

Remarks

This method is used to attach a client handle created outside of the class using the SocketTools API. Once the client handle is attached to the class, the other class member functions may be used with that client session.

If a client handle has already been created for the class, that handle will be released when the new handle is attached to the class object. If you want to prevent the previous client session from being terminated, you must call the **DetachHandle** method. Failure to release the detached handle may result in a resource leak in your application.

Note that the ***hClient*** parameter is presumed to be a valid client handle and no checks are performed to ensure that the handle is valid. Specifying an invalid client handle will cause subsequent method calls to fail.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

See Also

AttachThread, DetachHandle, GetHandle

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSshClient::AttachThread Method

```
DWORD AttachThread(
   DWORD dwThreadId
);
```

The **AttachThread** method attaches the specified client handle to another thread.

Parameters

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the method succeeds, the return value is the thread ID of the previous owner. If the method fails, the return value is SSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

When a client handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in a client application to create the client handle, and then pass that handle to another worker thread. The **AttachThread** method can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the method, the original owner of the handle can be restored before the worker thread terminates.

This method should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **AttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **Cancel** method and then release the handle after the blocking method exits and control is returned to the current thread.

Note that the ***dwThreadId*** parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the client handle used by the class until the destructor is called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

See Also

AttachHandle, Cancel, Connect, DetachHandle, Disconnect, GetHandle

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSshClient::Break Method

```
INT Break();
```

The **Break** method sends a signal to the server.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is SSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **Break** method sends a control message to the server which simulates a break signal on a physical terminal. This is used by some operating systems as an instruction to enter a privileged configuration mode. Note that this is not the same as sending an interrupt character such as Ctrl+C to the server. This control code is ignored for SSH 1.0 sessions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

Cancel, Control, Read, ReadLine, Write, WriteLine

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSshClient::Cancel Method

```
INT Cancel();
```

The **Cancel** method cancels any outstanding blocking operation in the client, causing the blocking method to fail. The application may then retry the operation or terminate the client session.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is SSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

When the **Cancel** method is called, the blocking method will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

Break, IsBlocking

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSshClient::Connect Method

```
BOOL Connect(
   LPCTSTR lpszRemoteHost,
   UINT nRemotePort,
   LPCTSTR lpszUserName,
   LPCTSTR lpszPassword,
   UINT nTimeout,
   DWORD dwOptions,
   LPSSHOPTIONDATA lpOptions
);
```

The **Connect** method establishes a connection with the specified server.

Parameters

lpszRemoteHost

The name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on. A value of zero specifies that the default port number 22 should be used.

lpszUserName

A null-terminated string which specifies the user name which will be used to authenticate the client session. This parameter must specify a valid user name and cannot be NULL or an empty string.

lpszPassword

A null-terminated string which specifies the password which will be used to authenticate the client session. If the user does not have a password, this parameter can be NULL or an empty string.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
SSH_OPTION_NONE	No options specified. A standard terminal session will be established with the default terminal type.
SSH_OPTION_KEEPALIVE	This option specifies the library should attempt to maintain an idle client session for long periods of time. This option is only necessary if you expect that the connection will be held open for an extended period of time. The actual client idle timeout period is determined by the server configuration.
SSH_OPTION_NOPTY	This option specifies that a pseudoterminal (PTY) should not be created for the client session. This option is automatically set if the SSH_OPTION_COMMAND option has been specified. This option should never be used with interactive client sessions.

SSH_OPTION_NOSHELL	This option specifies that a command shell should not be used when executing a command on the server. You should not use this option unless you require the command to execute without the normal shell environment. In most cases you should not use this option because it may cause commands to fail unexpectedly.
SSH_OPTION_TERMINAL	This option specifies the client session will use terminal emulation and the SSHOPTIONDATA structure specifies the characteristics of the virtual terminal. This enables the caller to specify the dimensions of the virtual display (in columns and rows) and the type of terminal that will be emulated. If this option is omitted, the session will default to a virtual display that is 80 columns, 25 rows.
SSH_OPTION_COMMAND	This option specifies the client session will be used to issue a command that is executed on the server, and the output will be returned to the caller. If this option is specified, the session will not be interactive and no pseudoterminal is created for the client. The szCommandLine member of the SSHOPTIONDATA structure specifies the command string that will be sent to the server.
SSH_OPTION_PROXYSERVER	This option specifies the client should establish a connection through a proxy server. The two protocols that are supported are SSH_PROXY_HTTP and SSH_PROXY_TELNET, which specifies the protocol that the proxy connection is created through. The proxy-related members of the SSHOPTIONDATA structure should be set to the appropriate values.
SSH_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
SSH_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.

lpOptions

A pointer to a SSHOPTIONDATA structure which specifies additional information for one or more options. If no optional data is required, a NULL pointer may be specified.

hEventWnd

The handle to the event notification window. This window receives messages which notify the client of various asynchronous network events that occur. If this argument is NULL, then the client session

will be blocking and no network events will be sent to the client.

uEventMsg

The message identifier that is used when an asynchronous network event occurs. This value should be greater than WM_USER as defined in the Windows header files. If the ***hEventWnd*** argument is NULL, this argument should be specified as WM_NULL.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method will block the current thread until a connection has been established or the timeout period has elapsed. To prevent it from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling the **Connect** method in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each connection.

By default, the client session will be authenticated using standard password authentication. If you prefer to authenticate using a private key file, you must create a SECURITYCREDENTIALS structure which specifies the path to the private key and optionally the password used when creating it. The private key file must be in the standard PEM format defined in RFC 1422. Both the standard RSA private key format and the proprietary OpenSSH format are supported. To determine how the private key was created, you can open the file in a text editor and the first line of the file will identify the format.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the class instance is initially attached to the thread that created it. From that point on, until the handle is released, only the owner may call methods using that instance of the class. The ownership of the class instance may be transferred from one thread to another using the **AttachThread** method.

Specifying the SSH_OPTION_FREETHREAD option enables any thread to call any method in that instance of the class, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the class instance is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same instance.

Example

```
CSshClient sshClient;
SSHOPTIONDATA sshOptions;
BOOL bConnected;

// Initialize the SSHOPTIONDATA structure and specify the
// command that should be executed on the server
ZeroMemory(&sshOptions, sizeof(sshOptions));
lstrcpyn(sshOptions.szCommandLine, strCommand, SSH_MAXCOMMANDLEN);

// Establish a connection with the SSH server

bConnected = sshClient.Connect(strHostName,
                               SSH_PORT_DEFAULT,
                               strUserName,
```

```
                                    strPassword,
                                    SSH_TIMEOUT,
                                    SSH_OPTION_COMMAND,
                                    &sshOptions);

// If the connection attempt fails, then get a description of
// the error and display it in a message box

if (!bConnected)
{
    sshClient.ShowError();
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib
Unicode: Implemented as Unicode and ANSI versions

SshClient::Control Method

```
INT Control(
   DWORD dwControlCode
);
```

The **SshControl** function sends a control message to the server.

Parameters

dwControlCode

A numeric control code which specifies the control message which should be sent to the server. This may be one of the following values:

Value	Description
SSH_CONTROL_BREAK	Sends a control message to the server which simulates a break signal on a physical terminal. This is used by some operating systems as an instruction to enter a privileged configuration mode. Note that this is not the same as sending an interrupt character such as Ctrl+C to the server. This control code is ignored for SSH 1.0 sessions.
SSH_CONTROL_NOOP	Sends a control message to the server, but it does not perform any operation. This is typically used by clients to prevent the server from automatically closing a session that has been idle for a long period of time.
SSH_CONTROL_EOF	Sends a control message to the server indicating that the client has finished sending data. Note that this option is normally not used with interactive terminal sessions, and should only be used when required by the server.
SSH_CONTROL_PING	Sends a control message to the server which is used to test whether or not the server is responsive to the client. This is typically used by clients to attempt to detect if the connection to the server is still active.
SSH_CONTROL_REKEY	Sends a control message to the server requesting that the key exchange be performed again. This control code is ignored for SSH 1.0 sessions.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SSH_ERROR. To get extended error information, call the **GetLastError** method.

Remarks

The **Control** method enables an application to send control messages to the server, which can cause it to take specific actions such as simulate a terminal break or request that the key exchanged be performed again. Some control messages are not supported by the SSH 1.0 protocol, in which case the control message is ignored.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

CSshClient::CreateSecurityCredentials Method

```
BOOL CreateSecurityCredentials(
   DWORD dwProtocol,
   DWORD dwOptions,
   LPCTSTR lpszKeyFile,
   LPCTSTR lpszPassword
);

BOOL CreateSecurityCredentials(
   LPCTSTR lpszKeyFile,
   LPCTSTR lpszPassword
);

BOOL CreateSecurityCredentials(
   LPCTSTR lpszKeyFile
);
```

The **CreateSecurityCredentials** method establishes the security credentials for the client session.

Parameters

dwProtocol

A bitmask of supported security protocols.

Value	Description
SECURITY_PROTOCOL_SSH2	Version 2.0 of the protocol will be used when establishing the connection. Currently, this is the only supported protocol option for SSH connections. In older versions of SocketTools, you had the option of selecting either version 1.0 or 2.0; however, version 1.0 is no longer considered secure and is not supported.

dwOptions

This parameter is reserved for future use and should always be a value of zero.

lpszKeyFile

A null-terminated string which specifies the name of a private key file that used when authenticating the client connection. The private key file must be in the standard PEM format defined in RFC 1422. Both the standard RSA private key format and the proprietary OpenSSH format are supported.

lpszPassword

A null-terminated string which specifies the password for the private key file. A value of NULL specifies that no password is required.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method is only required if you wish to authenticate the client session using a private key file instead of an account password.

The ***lpszKeyFile*** path can use environment variables enclosed in percent symbols, and the path to the

private key file will be normalized. It is recommended you always use an absolute path to the private key file. If you do not include a path, it will use the current working directory for the process. This can produce inconsistent results with multithreaded applications because the current working directory for a process is a global value and it can be changed by any thread at any time.

Example

```
CSshClient sshClient;
LPCTSTR lpszKeyFile = _T("%USERPROFILE%\\.ssh\\id_rsa.pem");

// Create the SECURITYCREDENTIALS structure and specify the
// path to the private key file for the current user
if (!sshClient.CreateSecurityCredentials(lpszKeyFile))
{
    sshClient.ShowError();
    return;
}

// Establish a connection with the SSH server on port 22
bConnected = sshClient.Connect(strHostName,
                               SSH_PORT_DEFAULT,
                               strUserName,
                               NULL, // No password, using a private key file
                               SSH_TIMEOUT,
                               SSH_OPTION_KEEPALIVE);

// If the connection attempt fails, then get a description of
// the error and display it in a message box

if (!bConnected)
{
    sshClient.ShowError();
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

CSshClient::DeleteSecurityCredentials Method

```
VOID DeleteSecurityCredentials();
```

The **DeleteSecurityCredentials** method releases the security credentials for the current session.

Parameters

None.

Return Value

None.

Remarks

This method can be used to release the memory allocated to the client or server credentials after a secure connection has been terminated. The security credentials are released when the class destructor is called, so it is normally not required that the application explicitly call this method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib
Unicode: Implemented as Unicode and ANSI versions

CSshClient::DetachHandle Method

```
HCLIENT DetachHandle();
```

The **DetachHandle** method detaches the client handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the client handle associated with the current instance of the class object. If there is no active client session, the value INVALID_CLIENT will be returned.

Remarks

This method is used to detach a client handle created by the class for use with the SocketTools API. Once the client handle is detached from the class, no other class member functions may be called. Note that the handle must be explicitly released at some later point by the process or a resource leak will occur.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

CSshClient::DisableEvents Method

```
INT DisableEvents();
```

The **DisableEvents** method disables the event notification mechanism, preventing subsequent event notification messages from being posted to the application's message queue.

This method has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is SSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **DisableEvents** method is used to disable event message posting for the specified client session. Although this will immediately prevent any new events from being generated, it is possible that messages could be waiting in the message queue. Therefore, an application must be prepared to handle client event messages after this method has been called.

This method is automatically called if the client has event notification enabled, and the **Disconnect** method is called. The same issues regarding outstanding event messages also applies in this situation, requiring that the application handle event messages that may reference a client handle that is no longer valid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

CSshClient::DisableTrace Method

```
BOOL DisableTrace();
```

The **DisableTrace** method disables the logging of network function calls.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, a value of zero is returned.

Remarks

This method will disable output to the log file for the current thread or process, depending on the flags used when logging was enabled. If this method is not called, the resources that were allocated for the logging session will be released when the process ends.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

EnableTrace

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSshClient::Disconnect Method

```
VOID Disconnect();
```

The **Disconnect** method terminates the connection with the server, closing the socket and releasing the memory allocated for the client session.

Parameters

None.

Return Value

None.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

Connect, IsConnected

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSshClient::EnableEvents Method

```
INT EnableEvents(
   HWND hEventWnd,
   UINT uEventMsg
);
```

The **EnableEvents** method enables event notifications using Windows messages.

This method has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Applications should use the **RegisterEvent** method to register an event handler which is invoked when an event occurs.

Parameters

hEventWnd

Handle to the window which will receive the client notification messages. This parameter must specify a valid window handle. If a NULL handle is specified, event notification will be disabled.

uEventMsg

The message that is received when a client event occurs. This value must be greater than 1024.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is SSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **EnableEvents** method is used to request that notification messages be posted to the specified window whenever a client event occurs. This allows an application to monitor the status of different client operations, such as a file transfer.

The *wParam* argument will contain the client handle, the low word of the *lParam* argument will contain the event ID, and the high word will contain any error code. If no error has occurred, the high word will always have a value of zero. The following events may be generated:

Value	Description
SSH_EVENT_CONNECT	The connection to the server has completed. The high word of the *lParam* parameter should be checked, since this notification message will be posted if an error has occurred.
SSH_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
SSH_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
SSH_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.

SSH_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
SSH_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

To disable event notification, call the **DisableEvents** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

See Also

DisableEvents, RegisterEvent

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSshClient::EnableTrace Method

```
BOOL EnableTrace(
   LPCTSTR lpszTraceFile,
   DWORD dwTraceFlags
);
```

The **EnableTrace** method enables the logging of network function calls to a file.

Parameters

lpszTraceFile

A null-terminated string which specifies the name of the logfile which will be appended to or created. It is recommended that this file always specify an absolute path to avoid any ambiguity. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
TRACE_INFO	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
TRACE_ERROR	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
TRACE_HEXDUMP	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
TRACE_TRUNCATE	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for

	multithreaded applications that are using worker threads.

Return Value

If the method succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the log file cannot be created.

Remarks

Logging is enabled and disabled at the thread or process level, depending on the flags passed to this method, and is not associated with a specific class instance. When logging is enabled, the information is appended to the specified file. If the file does not exist, it will be created. To limit the size of the file, enable and disable logging only around those sections of code that you wish to debug. If you do not provide a full path to the file, it will be relative to the current working directory for the process. This can produce unexpected results in multithreaded applications because the current directory is global to the entire process and can be changed by any thread at any time.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

The TRACE_HEXDUMP option can generate very large files because it includes all of the data exchanged between your application and the remote host. The TRACE_TRUNCATE option is only evaluated when logging is first enabled for a thread or process. If logging is already active, specifying this option will have no effect.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "**0x**". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxxx:xxxx::xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, a connection is being made to a system with the IPv4 address 192.0.0.1 on port 1234.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib
Unicode: Implemented as Unicode and ANSI versions

CSshClient::Execute Method

```
INT Execute(
   LPCTSTR lpszRemoteHost,
   UINT nRemotePort,
   LPCTSTR lpszUserName,
   LPCTSTR lpszPassword,
   LPCTSTR lpszCommandLine,
   UINT nTimeout,
   DWORD dwOptions,
   HGLOBAL* lphgblBuffer,
   LPDWORD lpdwLength
);

INT Execute(
   LPCTSTR lpszRemoteHost,
   UINT nRemotePort,
   LPCTSTR lpszUserName,
   LPCTSTR lpszPassword,
   LPCTSTR lpszCommandLine,
   UINT nTimeout,
   DWORD dwOptions,
   LPBYTE lpBuffer,
   LPDWORD lpdwLength
);

INT Execute(
   LPCTSTR lpszRemoteHost,
   UINT nRemotePort,
   LPCTSTR lpszUserName,
   LPCTSTR lpszPassword,
   LPCTSTR lpszCommandLine,
   UINT nTimeout,
   DWORD dwOptions,
   CString& strBuffer
);
```

The **Execute** method executes a command on the server and returns the output in the specified buffer.

Parameters

lpszRemoteHost

A null-terminated string which specifies the name of the server. This may either be a fully-qualified domain name, or an IP address. This parameter cannot be NULL.

nRemotePort

The port number the server is listening on. A value of zero specifies that the default port number 22 should be used.

lpszUserName

A null-terminated string which specifies the user name which will be used to authenticate the client session.

lpszPassword

A null-terminated string which specifies the password which will be used to authenticate the client

session.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
SSH_OPTION_NONE	No options specified. A standard terminal session will be established with the default terminal type.
SSH_OPTION_KEEPALIVE	This option specifies the library should attempt to maintain an idle client session for long periods of time. This option is only necessary if you expect that the connection will be held open for more than two hours.
SSH_OPTION_NOPTY	This option specifies that a pseudoterminal (PTY) should not be created for the client session. This option is automatically set if the SSH_OPTION_COMMAND option has been specified.
SSH_OPTION_NOSHELL	This option specifies that a command shell should not be used when executing a command on the server.
SSH_OPTION_NOAUTHRSA	This option specifies that RSA authentication should not be used with SSH-1 connections. This option is ignored with SSH-2 connections and should only be specified if required by the server.
SSH_OPTION_NOPWDNULL	This option specifies the user password cannot be terminated with a null character. This option is ignored with SSH-2 connections and should only be specified if required by the server.
SSH_OPTION_NOREKEY	This option specifies the client should never attempt a repeat key exchange with the server. Some SSH servers do not support rekeying the session, and this can cause the client to become non-responsive or abort the connection after being connected for an hour.
SSH_OPTION_COMPATSID	This compatibility option changes how the session ID is handled during public key authentication with older SSH servers. This option should only be specified when connecting to servers that use OpenSSH 2.2.0 or earlier versions.
SSH_OPTION_COMPATHMAC	This compatibility option changes how the HMAC authentication codes are generated. This option should only be specified when connecting to servers that use OpenSSH 2.2.0 or earlier versions.

lpBuffer, lphgblBuffer or strBuffer

A buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the function returns. If the application is using MFC, then a CString variable may also be specified, in which case the data is returned in the string

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the ***lpvBuffer*** parameter. If the ***lpvBuffer*** parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual length of the file that was downloaded.

lpCredentials

A pointer to a SECURITYCREDENTIALS structure which specifies additional security-related information required to establish the connection. This parameter may be NULL, in which case default values will be used. Note that the ***dwSize*** member must be initialized to the size of the **SECURITYCREDENTIALS** structure that is being passed to the function.

Return Value

If the function succeeds, the return value is the exit code from the program that was executed on the server. If the function fails, the return value is SSH_ERROR. To get extended error information, call **SshGetLastError**.

Remarks

The **Execute** method is used to execute a command on a server, read the output from that command and copy it into a local buffer. This method cannot be used if the connection to the server must be established through a proxy server; if a proxy server must be used, then you should use the **Connect** method to establish the connection, and then use either the **Read** or **ReadLine** methods to read the output.

This method may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the command output. In this case, the ***lpBuffer*** parameter will point to the buffer that was allocated, the value that the ***lpdwLength*** parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the ***lphgblBuffer*** parameter point to a global memory handle which will contain the output when the function returns. In this case, the value that the ***lpdwLength*** parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur. See the example code below.

When the command output is being read from the server, this method will automatically convert the data to match the end-of-line convention used on the Windows platform. This is useful when executing a command on a UNIX based system where the end-of-line is indicated by a single linefeed, while on Windows it is a carriage-return and linefeed pair. If the output contains embedded nulls or escape sequences, then this conversion will not be performed.

This method will cause the current thread to block until the command completes or a timeout occurs.

Example

```
HGLOBAL hgblBuffer = (HGLOBAL)NULL;
LPBYTE lpBuffer = (LPBYTE)NULL;
DWORD cbBuffer = 0;

// Execute a command on the server and return the data into block
// of global memory allocated by the GlobalAlloc function; the handle
```

```
// to this memory will be returned in the hgblBuffer parameter
nResult = sshClient.Execute(strHostName,
                            SSH_PORT_DEFAULT,
                            strUserName,
                            strPassword,
                            strCommandLine,
                            SSH_TIMEOUT,
                            SSH_OPTION_NONE,
                            &hgblBuffer,
                            &cbBuffer);

if (nResult != SSH_ERROR)
{
    // Lock the global memory handle, returning a pointer to the
    // resource data
    lpBuffer = (LPBYTE)::GlobalLock(hgblBuffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    ::GlobalUnlock(hgblBuffer);
    ::GlobalFree(hgblBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Server: Requires Windows Server 2003 or Windows 2000 Server.
Header File: cstools12.h
Import Library: cstshv12.lib
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSshClient::FreezeEvents Method

```
INT FreezeEvents(
   BOOL bFreeze
);
```

The **FreezeEvents** method is used to suspend and resume event handling by the client.

Parameters

bFreeze

A non-zero value specifies that event handling should be suspended by the client. A zero value specifies that event handling should be resumed.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is SSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

This method should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all client events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if the client has suspended event handling, and four read events occur, once event handling is resumed only one of those read events will be posted to the client. This prevents the application from being flooded by a potentially large number of queued events.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib
Unicode: Implemented as Unicode and ANSI versions

CSshClient::GetErrorString Method

```
INT GetErrorString(
   DWORD dwErrorCode,
   LPTSTR lpszDescription,
   INT nMaxLength
);

INT GetErrorString(
   DWORD dwErrorCode,
   CString& strDescription
);
```

The **GetErrorString** method is used to return a description of a specific error code. Typically this is used in conjunction with the **GetLastError** method for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

The buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length. An alternate form of the method accepts a **CString** variable which will contain the error description.

nMaxLength

The maximum number of characters that may be copied into the description buffer.

Return Value

If the method succeeds, the return value is the length of the description string. If the method fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the method is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CSshClient::GetExitCode Method

```
INT GetExitCode();
```

The **GetExitCode** function returns the exit code for the remote session.

Parameters

None.

Return Value

If the method succeeds, the return value is the numeric exit code. If the function fails, the return value is SSH_ERROR. To get extended error information, call the **GetLastError** method.

Remarks

This method should only be called after the command has completed and the **Read** method has returned a value of zero. In most cases, an exit code value of zero indicates success, while any other value indicates an error condition.

Note that the actual value is application dependent and is only meaningful in the context of that particular program. A program may choose or use exit codes in a non-standard way, such as having certain non-zero values indicate success.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

See Also

GetStatus

CSshClient::GetHandle Method

```
HCLIENT GetHandle();
```

The **GetHandle** method returns the client handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the client handle associated with the current instance of the class object. If there is no active client session, the value INVALID_CLIENT will be returned.

Remarks

This method is used to obtain the client handle created by the class for use with the SocketTools API.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

See Also

CSshClient::GetLastError Method

```
DWORD GetLastError();

DWORD GetLastError(
   CString& strDescription
);
```

Parameters

strDescription

A string which will contain a description of the last error code value when the method returns. If no error has been set, or the last error code has been cleared, this string will be empty.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **SetLastError** method. The Return Value section of each reference page notes the conditions under which the method sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **GetLastError** method immediately when a method's return value indicates that an error has occurred. That is because some methods call **SetLastError**(0) when they succeed, clearing the error code set by the most recently failed method.

Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or SSH_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

The description of the error code is the same string that is returned by the **GetErrorString** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

See Also

CSshClient::GetLineMode Method

```
INT GetLineMode();
```

The **GetLineMode** method returns the current line mode.

Parameters

None.

Return Value

If the method succeeds, the return value is the current line mode. If the method fails, the return value is SSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetLineMode** method returns an integer value that specifies how end-of-line character sequences are sent to the server. For more information about how newlines are processed by the class and the available options, refer to the **SetLineMode** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

See Also

CSshClient::GetSecurityInformation Method

```
BOOL GetSecurityInformation(
   LPSECURITYINFO lpSecurityInfo
);
```

The **GetSecurityInformation** method returns security protocol, encryption and certificate information about the current client connection.

Parameters

lpSecurityInfo

A pointer to a SECURITYINFO structure which contains information about the current client connection. The *dwSize* member of this structure must be initialized to the size of the structure before passing the address of the structure to this method.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method is used to obtain security related information about the current client connection to the server. It can be used to determine if a secure connection has been established, what security protocol was selected, and information about the server certificate. Note that a secure connection has not been established, the *dwProtocol* structure member will contain the value SECURITY_PROTOCOL_NONE.

Example

```
// Get the server fingerprint
SECURITYINFO securityInfo;

ZeroMemory(&securityInfo, sizeof(SECURITYINFO));
securityInfo.dwSize = sizeof(SECURITYINFO);

if (sshClient.GetSecurityInformation(&securityInfo))
{
    if (securityInfo.lpszFingerprint != NULL)
    {
        TCHAR szMessage[256];
        wsprintf(szMessage, _T("The fingerprint is %s",
securityInfo.lpszFingerprint);
        MessageBox(NULL, szMessage, "Connection", MB_OK);
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

Connect, CreateSecurityCredentials, SECURITYINFO

CSshClient::GetStatus Method

```
INT GetStatus();
```

The **GetStatus** method the current status of the client session.

Parameters

None.

Return Value

If the method succeeds, the return value is the client status code. If the method fails, the return value is SSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetStatus** method returns a numeric code which identifies the current state of the client session. The following values may be returned:

Value	Description
SSH_STATUS_UNUSED	No connection has been established.
SSH_STATUS_IDLE	The client is current idle and not sending or receiving data.
SSH_STATUS_CONNECT	The client is establishing a connection with the server.
SSH_STATUS_AUTHENTICATE	The client is authenticating the session with the server.
SSH_STATUS_READ	The client is reading data from the server.
SSH_STATUS_WRITE	The client is writing data to the server.
6	SSH_STATUS_DISCONNECT	The client is disconnecting from the server.

In a multithreaded application, any thread in the current process may call this method to obtain status information for the specified client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

See Also

IsBlocking, IsConnected, IsReadable, IsWritable

CSshClient::GetTimeout Method

```
INT GetTimeout();
```

The **GetTimeout** method returns the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the method will fail and return to the caller.

Parameters

None.

Return Value

If the method succeeds, the return value is the timeout period in seconds. If the method fails, the return value is SSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

The timeout value is only used with blocking client connections. A value of zero indicates that the default timeout period of 20 seconds should be used.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

See Also

Connect, IsReadable, IsWritable, Read, SetTimeout, Write

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSshClient::IsBlocking Method

```
BOOL IsBlocking();
```

The **IsBlocking** method is used to determine if the client is currently performing a blocking operation.

Parameters

None.

Return Value

If the client is performing a blocking operation, the method returns a non-zero value. If the client is not performing a blocking operation, or the client handle is invalid, the method returns zero.

Remarks

Because a blocking operation can allow the application to be re-entered (for example, by pressing a button while the operation is being performed), it is possible that another blocking method may be called while it is in progress. Since only one thread of execution may perform a blocking operation at any one time, an error would occur. The **IsBlocking** method can be used to determine if the client is already blocked, and if so, take some other action (such as warning the user that they must wait for the operation to complete).

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

Cancel, GetStatus, IsConnected, IsInitialized, IsReadable, IsWritable, Read, Write

CSshClient::IsConnected Method

```
BOOL IsConnected();
```

The **IsConnected** method is used to determine if the client is currently connected to a server.

Parameters

None.

Return Value

If the client is connected to a server, the method returns a non-zero value. If the client is not connected, or the client handle is invalid, the method returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

See Also

GetStatus, IsBlocking, IsInitialized, IsReadable, IsWritable

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSshClient::IsInitialized Method

```
BOOL IsInitialized();
```

The **IsInitialized** method returns whether or not the class object has been successfully initialized.

Parameters

None.

Return Value

This method returns a non-zero value if the class object has been successfully initialized. A return value of zero indicates that the runtime license key could not be validated or the networking library could not be loaded by the current process.

Remarks

When an instance of the class is created, the class constructor will attempt to initialize the component with the runtime license key that was created when SocketTools was installed. If the constructor is unable to validate the license key or load the networking libraries, this initialization will fail.

If SocketTools was installed with an evaluation license, the application cannot be redistributed to another system. The class object will fail to initialize if the application is executed on another system, or if the evaluation period has expired. To redistribute your application, you must purchase a development license which will include the runtime key that is needed to redistribute your software to other systems. Refer to the Developer's Guide for more information.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

CSshClient::IsReadable Method

```
BOOL IsReadable(
   INT nTimeout,
   LPDWORD lpdwAvail
);
```

The **IsReadable** method is used to determine if data is available to be read from the server.

Parameters

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

lpdwAvail

A pointer to an unsigned integer which will contain the number of bytes available to read. This parameter may be NULL if this information is not required.

Return Value

If the client can read data from the server within the specified timeout period, the method returns a non-zero value. If the client cannot read any data, the method returns zero.

Remarks

On some platforms, this value will not exceed the size of the receive buffer (typically 8192 bytes). Because of differences between TCP/IP stack implementations, it is not recommended that your application exclusively depend on this value to determine the exact number of bytes available. Instead, it should be used as a general indicator that there is data available to be read.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

See Also

GetStatus, IsBlocking, IsConnected, IsInitialized, IsWritable, Write

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSshClient::IsWritable Method

```
BOOL IsWritable(
   INT nTimeout
);
```

The **IsWritable** method is used to determine if data can be written to the server.

Parameters

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

Return Value

If the client can write data to the server within the specified timeout period, the method returns a non-zero value. If the client cannot write any data, the method returns zero.

Remarks

Although this method can be used to determine if some amount of data can be sent to the remote process it does not indicate the amount of data that can be written without blocking the client. In most cases, it is recommended that large amounts of data be broken into smaller logical blocks, typically some multiple of 512 bytes in length.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

See Also

CSshClient::Peek Method

```
INT Peek(
   LPBYTE lpBuffer,
   INT cbBuffer
);

INT Peek(
   CString& strBuffer,
   INT cbBuffer
);
```

The **Peek** method reads the specified number of bytes from the server and copies them into the buffer, but it does not remove the data from the internal receive buffer. The data may be of any type, and is not terminated with a null character.

Parameters

lpBuffer

Pointer to the buffer in which the data will be copied. An alternate form of this method allows a **CString** variable to be passed and data read from the socket will be returned in that string.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

Return Value

If the method succeeds, the return value is the number of bytes actually read. A return value of zero indicates that the server has closed the connection and there is no more data available to be read. If the method fails, the return value is SSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **Peek** method can be used to examine the data that is available to be read from the internal receive buffer. If there is no data in the receive buffer at that time, a value of zero is returned. It should be noted that this differs from the **Read** method, where a return value of zero indicates that there is no more data available to be read and the connection has been closed. The **Peek** method will never cause the client to block, and so may be safely used with asynchronous connections.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

See Also

IsBlocking, IsReadable, Read, ReadLine, Write, WriteLine

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSshClient::Read Method

```
INT Read(
   LPBYTE lpBuffer,
   INT cbBuffer
);

INT Read(
   CString& strBuffer,
   INT cbBuffer
);
```

The **Read** method reads the specified number of bytes from the client socket and copies them into the buffer. The data may be of any type, and is not terminated with a null character.

Parameters

lpBuffer

Pointer to the buffer in which the data will be copied. An alternate form of this method allows a **CString** variable to be passed and data read from the socket will be returned in that string.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

Return Value

If the method succeeds, the return value is the number of bytes actually read. A return value of zero indicates that the server has closed the connection and there is no more data available to be read. If the method fails, the return value is SSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

When **Read** is called and the client is in non-blocking mode, it is possible that the method will fail because there is no available data to read at that time. This should not be considered a fatal error. Instead, the application should simply wait to receive the next asynchronous notification that data is available.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

See Also

IsBlocking, IsReadable, Peek, ReadLine, Write, WriteLine

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSshClient::ReadLine Method

```
BOOL ReadLine(
   LPTSTR lpszBuffer,
   LPINT lpnLength
);

BOOL ReadLine(
   LPTSTR lpszBuffer,
   INT nMaxLength
);

BOOL ReadLine(
   CString& strBuffer,
   INT nMaxLength
);
```

The **ReadLine** method reads up to a line of data from the server and returns it in a string buffer.

Parameters

lpszBuffer

Pointer to the string buffer that will contain the data when the method returns. The string will be terminated with a null character, and will not contain the end-of-line characters. An alternate form of the method accepts a **CString** argument which will contain the line of text returned by the server.

lpnLength

A pointer to an integer value which specifies the length of the buffer. The value should be initialized to the maximum number of characters that can be copied into the string buffer, including the terminating null character. When the method returns, its value will updated with the actual length of the string.

nMaxLength

An integer value which specifies the maximum length of the buffer.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **ReadLine** method reads data from the server and copies into a specified string buffer. Unlike the **Read** method which reads arbitrary bytes of data, this method is specifically designed to return a single line of text data in a string. When an end-of-line character sequence is encountered, the method will stop and return the data up to that point. The string buffer is guaranteed to be null-terminated and will not contain the end-of-line characters.

There are some limitations when using **ReadLine**. The method should only be used to read text, never binary data. In particular, the method will discard nulls, linefeed and carriage return control characters. The Unicode version of this method will return a Unicode string, however it does not support reading raw Unicode data from the socket. Any data read from the socket is internally buffered as octets (eight-bit bytes) and converted to Unicode using the **MultiByteToWideChar** function.

This method will force the thread to block until an end-of-line character sequence is processed, the read operation times out or the server closes its end of the socket connection. If this method is called

with asynchronous events enabled, it will automatically switch the socket into a blocking mode, read the data and then restore the socket to asynchronous operation. If another socket operation is attempted while **ReadLine** is blocked waiting for data from the server, an error will occur. It is recommended that this method only be used with blocking (synchronous) socket connections; if the application needs to establish multiple simultaneous connections, it should create worker threads to manage each connection.

The **Read** and **ReadLine** method calls can be intermixed, however be aware that **Read** will consume any data that has already been buffered by the **ReadLine** method and this may have unexpected results.

Unlike the **Read** method, it is possible for data to be returned in the string buffer even if the return value is zero. Applications should check the length of the string to determine if any data was copied into the buffer. For example, if a timeout occurs while the method is waiting for more data to arrive on the socket, it will return zero; however, data may have already been copied into the string buffer prior to the error condition. It is the responsibility of the application to process that data, regardless of the return value.

Example

```
CString strBuffer;
BOOL bResult;

do
{
    bResult = pClient->ReadLine(strBuffer);

    if (strBuffer.GetLength() > 0)
    {
        // Process the line of data returned in the string
        // buffer; the string is always null-terminated
    }
} while (bResult);

DWORD dwError = pClient->GetLastError();

if (dwError == ST_ERROR_CONNECTION_CLOSED)
{
    // The server has closed its side of the connection and
    // there is no more data available to be read
}
else if (dwError != 0)
{
    // An error has occurred while reading a line of data
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib
Unicode: Implemented as Unicode and ANSI versions

CSshClient::RegisterEvent Method

```
INT RegisterEvent(
   UINT nEventId,
   SSHEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

The **RegisterEvent** method registers an event handler for the specified event.

Parameters

nEventId

An unsigned integer which specifies which event should be registered with the specified callback function. One of the following values may be used:

Value	Description
SSH_EVENT_CONNECT	The connection to the server has completed.
SSH_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
SSH_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
SSH_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
SSH_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
SSH_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **SshEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is SSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **RegisterEvent** method associates a callback function with a specific event. The event handler is an **SshEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

The callback function specified by the ***lpEventProc*** parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

The ***dwParam*** parameter is commonly used to identify the class instance which is associated with the event that has occurred. Applications will cast the **this** pointer to a DWORD_PTR value when calling this function, and then the event handler will cast it back to a pointer to the class instance. This gives the handler access to the class member variables and methods.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

CSshClient::Search Method

```
BOOL Search(
   LPCTSTR lpszString
);

BOOL Search(
   LPCTSTR lpszString,
   LPBYTE lpBuffer,
   LPDWORD lpdwLength
);

BOOL Search(
   LPCTSTR lpszString,
   HGLOBAL *lpBuffer,
   LPDWORD lpdwLength
);

BOOL Search(
   LPCTSTR lpszString,
   CString& strBuffer
);
```

The **Search** method searches for a specific character sequence in the data stream and stops reading if the sequence is encountered.

Parameters

lpszString

A null-terminated string which specifies the sequence of characters to search for in the data stream. This parameter cannot be NULL or point to an empty string.

lpBuffer

A buffer which will contain the output from the server, or a pointer to a global memory handle which will reference the output when the method returns. If the output from the server is not required, this parameter may be NULL.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the ***lpBuffer*** parameter. If the ***lpBuffer*** parameter points to a global memory handle, the length value should be initialized to zero. When the method returns, this value will be updated with the actual number of bytes of output stored in the buffer. If the ***lpBuffer*** parameter is NULL, this parameter should also be NULL.

Return Value

If the method succeeds and the character sequences was found in the data stream, the return value is non-zero. If the method fails or a timeout occurs before the sequence is found, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **Search** method searches for a character sequence in the data stream and stops reading when it is found. This is useful when the client wants to automate responses to the server, such as logging in a user and executing a command. The method collects the output from the server and stores it in the buffer specified by the ***lpBuffer*** parameter. When the method returns, the buffer will contain everything sent by the server up to and including the search string.

The *lpBuffer* parameter may be specified in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the a fixed amount of output. In this case, the *lpBuffer* parameter will point to the buffer that was allocated, the value that the *lpdwLength* parameter points to should be initialized to the size of that buffer. If the server sends more output than can be stored in the buffer, the remaining output will be discarded.

The second method that can be used is have the *lpBuffer* parameter point to a global memory handle which will contain the output when the method returns. In this case, the value that the *lpdwLength* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the method must be freed by the application, otherwise a memory leak will occur. This method is preferred if the client application does not have a general idea of how much output will be generated until the search string is found.

Example

```
LPCTSTR lpszCommand = _T("/bin/ls -l\r\n");
LPCTSTR lpszPrompt = _T("$ ");
HGLOBAL hgblOutput = NULL;
DWORD cbOutput = 0;
BOOL bResult;

// Search for a command prompt issued by the server

bResult = pClient->Search(lpszPrompt, NULL, NULL, 0);

// If the shell prompt was found, issue the command
// and capture the output into the hgblBuffer global
// memory buffer; the cbBuffer variable will contain
// the actual number of bytes in the buffer when the
// function returns

if (bResult)
{
    pClient->Write((LPBYTE)lpszCommand, lstrlen(lpszCommand));

    bResult = pClient->Search(lpszPrompt,
                              &hgblOutput,
                              &cbOutput,
                              0);
}

// Write the contents of the output buffer to the
// standard output stream

if (bResult)
{
    LPBYTE lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    if (lpBuffer)
        fwrite(lpBuffer, 1, cbBuffer, stdout);

    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

CSshClient::SetLastError Method

```
VOID SetLastError(
   DWORD dwErrorCode
);
```

The **SetLastError** method sets the last error code for the current thread. This method is typically used to clear the last error by specifying a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or SSH_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

Applications can retrieve the value saved by this method by using the **GetLastError** method. The use of **GetLastError** is optional; an application can call the method to determine the specific reason for a method failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

CSshClient::SetLineMode Method

```
INT SetLineMode(
   INT nLineMode
);
```

The **SetLineMode** method changes the current line mode for the client session.

Parameters

nLineMode

An integer value which specifies how the newlines are sent by the class. It must be one of the following values:

Value	Description
SSH_NEWLINE_DEFAULT	There are no changes to how data is sent to the server. Any carriage return or linefeed characters that are sent using the **Write** method will be sent as-is. The **WriteLine** method will terminate each line of text with a carriage return and linefeed (CRLF) sequence. This is the default line mode that is set when a new connection is established.
SSH_NEWLINE_CR	A carriage return is used as the end-of-line character. Any data sent using the **Write** method that contains only a linefeed (LF) character or a carriage return and linefeed (CRLF) sequence to indicate the end-of-line will be replaced by a carriage return (CR) character. The **WriteLine** method will terminate each line of text with a single carriage return character.
SSH_NEWLINE_LF	A linefeed is used as the end-of-line character. Any data sent using the **Write** method that contains only a carriage return (CR) character or a carriage return an linefeed (CRLF) sequence to indicate the end-of-line will be replaced by a linefeed (LF) character. The **WriteLine** method will terminate each line of text with a single linefeed character.
SSH_NEWLINE_CRLF	A carriage return and linefeed (CRLF) character sequence is used to indicate the end-of-line. Any data sent using the **Write** method that contains only a carriage return (CR) or linefeed (LF) will be replaced by a carriage return and linefeed. The **WriteLine** method will terminate each line of text with a carriage return and linefeed sequence.

Return Value

If the method succeeds, the return value is the previous line mode for the client session. If the method fails, the return value is SSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

When a connection is initially established with the server, it determines what characters are used to indicate the end-of-line and how they are displayed. On UNIX based systems, this is controlled by the settings for the pseudo-terminal that is allocated for the client session, and can be changed using the **stty** command. In most cases, the client line mode can be left at the default. However, in some cases

you may need to change the line mode, particularly if you intend to send data from a Windows text file or copied from the clipboard.

Windows uses a carriage return and linefeed (CRLF) sequence to indicate the end-of-line and a UNIX based server may interpret that as multiple newlines. To prevent this, use the **SetLineMode** method to change the current line mode to **SSH_NEWLINE_CR** and the CRLF sequence in the text will be replaced by a single carriage return.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

CSshClient::SetTimeout Method

```
INT SetTimeout(
   UINT nTimeout
);
```

The **SetTimeout** method sets the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the method will fail and return to the caller.

Parameters

nTimeout

The number of seconds to wait for a blocking operation to complete.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is SSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

The timeout value is only used with blocking client connections.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

CSshClient::ShowError Method

```
INT ShowError(
   LPCTSTR lpszAppTitle,
   UINT uType,
   DWORD dwErrorCode
);
```

The **ShowError** method displays a message box which describes the specified error.

Parameters

lpszAppTitle

A null-terminated string which specifies the title of the message box that is displayed. If this argument is NULL or omitted, then the default title of "Error" will be displayed.

uType

An unsigned integer which specifies the type of message box that will be displayed. This is the same value that is used by the **MessageBox** method in the Windows API. If a value of zero is specified, then a message box with a single OK button will be displayed. Refer to that method for a complete list of options.

dwErrorCode

Specifies the error code that will be used when displaying the message box. If this argument is zero, then the last error that occurred in the current thread will be displayed.

Return Value

If the method is successful, the return value will be the return value from the **MessageBox** function. If the method fails, it will return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib
Unicode: Implemented as Unicode and ANSI versions

CSshClient::Write Method

```
INT Write(
   LPBYTE lpBuffer,
   INT cbBuffer
);

INT Write(
   LPCTSTR lpszBuffer
   INT cbBuffer
);
```

The **Write** method sends the specified number of bytes to the server.

Parameters

lpBuffer

The pointer to the buffer which contains the data that is to be sent to the server. In an alternate form of the method, the pointer is to a string.

cbBuffer

The number of bytes to send from the specified buffer. This value must be greater than zero, unless a pointer to a string buffer is passed as the parameter. In that case, if the value is -1, all of the characters in the string, up to but not including the terminating null character, will be sent to the server.

Return Value

If the method succeeds, the return value is the number of bytes actually written. If the method fails, the return value is SSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

The return value may be less than the number of bytes specified by the ***cbBuffer*** parameter. In this case, the data has been partially written and it is the responsibility of the client application to send the remaining data at some later point. For non-blocking clients, the client must wait for the next asynchronous notification message before it resumes sending data.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CSshClient::WriteLine Method

```
BOOL WriteLine(
   LPCTSTR lpszBuffer,
   LPINT lpnLength
);
```

The **WriteLine** function sends a line of text to the server, terminated by a carriage-return and linefeed.

Parameters

lpszBuffer

The pointer to a string buffer which contains the data that will be sent to the server. All characters up to, but not including, the terminating null character will be written to the socket. The data will always be terminated with a carriage-return and linefeed control character sequence. If this parameter points to an empty string or NULL pointer, then a only a carriage-return and linefeed are written to the socket.

lpnLength

A pointer to an integer value which will contain the number of characters written to the socket, including the carriage-return and linefeed sequence. If this information is not required, a NULL pointer may be specified.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **WriteLine** method writes a line of text to the server and terminates the line with a carriage-return and linefeed control character sequence. Unlike the **Write** method which writes arbitrary bytes of data to the socket, this method is specifically designed to write a single line of text data from a string.

If the *lpszBuffer* string is terminated with a linefeed (LF) or carriage return (CR) character, it will be automatically converted to a standard CRLF end-of-line sequence. Because the string will be sent with a terminating CRLF sequence, the value returned in the *lpnLength* parameter will typically be larger than the original string length (reflecting the additional CR and LF characters), unless the string was already terminated with CRLF.

There are some limitations when using **WriteLine**. This method should only be used to send text, never binary data. In particular, it will discard nulls and append linefeed and carriage return control characters to the data stream. The Unicode version of this method will accept a Unicode string, however it does not support writing raw Unicode data to the socket. Unicode strings will be automatically converted to UTF-8 encoding using the **WideCharToMultiByte** function and then written to the socket as a stream of bytes.

This method will force the thread to block until the complete line of text has been written, the write operation times out or the server aborts the connection. If this method is called with asynchronous events enabled, it will automatically switch the socket into a blocking mode, send the data and then restore the socket to asynchronous operation. If another socket operation is attempted while **WriteLine** is blocked sending data to the server, an error will occur. It is recommended that this method only be used with blocking (synchronous) socket connections; if the application needs to establish multiple simultaneous connections, it should create worker threads to manage each

connection.

The **Write** and **WriteLine** methods can be safely intermixed.

Unlike the **Write** function, it is possible for data to have been written to the socket if the return value is zero. For example, if a timeout occurs while the method is waiting to send more data to the server, it will return zero; however, some data may have already been written prior to the error condition. If this is the case, the ***lpnLength*** argument will specify the number of characters actually written up to that point.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

SSH Protocol Data Structures

- SECURITYCREDENTIALS
- SECURITYINFO
- SSHOPTIONDATA

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SECURITYCREDENTIALS

The **SECURITYCREDENTIALS** structure specifies the information needed by the library to specify additional security credentials, such as a client certificate or private key, when establishing a secure connection.

```
typedef struct _SECURITYCREDENTIALS
{
    DWORD    dwSize;
    DWORD    dwProtocol;
    DWORD    dwOptions;
    DWORD    dwReserved;
    LPCTSTR  lpszHostName;
    LPCTSTR  lpszUserName;
    LPCTSTR  lpszPassword;
    LPCTSTR  lpszCertStore;
    LPCTSTR  lpszCertName;
    LPCTSTR  lpszKeyFile;
} SECURITYCREDENTIALS, *LPSECURITYCREDENTIALS;
```

Members

dwSize

Size of this structure. If the structure is being allocated dynamically, this member must be set to the size of the structure.

dwProtocol

A value which specifies which security protocols are supported:

Value	Description
SECURITY_PROTOCOL_SSH2	Version 2.0 of the protocol will be used when establishing the connection. Currently, this is the only supported protocol option for SSH connections. In older versions of SocketTools, you had the option of selecting either version 1.0 or 2.0; however, version 1.0 is no longer considered secure and is not supported.

dwOptions

This structure member is reserved for use with TLS connections and should always be initialized to zero.

dwReserved

This structure member is reserved for future use and should always be initialized to zero.

lpszHostName

A null-terminated string which specifies the hostname that will be used when validating a server certificate. This member should always be initialized as a NULL pointer for connections using the SSH protocol.

lpszUserName

A null-terminated string which identifies the owner of client certificate. Currently this member is not used by the library and should always be initialized as a NULL pointer.

lpszPassword

A null-terminated string which specifies the password needed to access the certificate. Currently this

member is only used if a private key file has been specified. If there is no password associated with the certificate, then this member should be initialized as a NULL pointer.

lpszCertStore

A null-terminated string which specifies the name of the certificate store to open. Although this member can be used to specify the path to a public key file in the OpenSSH format, this is not required. In most cases this member should be initialized as a NULL pointer for connections using the SSH protocol.

lpszCertName

A null-terminated string which specifies the name of the certificate to use. This member should always be initialized as a NULL pointer for connections using the SSH protocol.

lpszKeyFile

A null-terminated string which specifies the name of the file which contains the private key required to establish the connection. This member is only used with the SSH protocol. If the member is NULL, then no private key is used. The private key file must be in the standard PEM format defined in RFC 1422. Both the standard RSA private key format and the proprietary OpenSSH format are supported.

Remarks

When using the C++ class, you do not need to explicitly define this structure. Instead, you can use the **CreateSecurityCredentials** method to specify the private key file. If the private key is protected with a password, the ***lpszPassword*** parameter must specify that value or the connection request will fail with an authentication error.

The ***lpszKeyFile*** path can use environment variables enclosed in percent symbols, and the path to the private key file will be normalized. It is recommended you always use an absolute path to the private key file. If you do not include a path, it will use the current working directory for the process. This can produce inconsistent results with multithreaded applications because the current working directory for a process is a global value and it can be changed by any thread at any time.

Example

```
CSshClient sshClient;
LPCTSTR lpszKeyFile = _T("%USERPROFILE%\\.ssh\\id_rsa.pem");

// Create the SECURITYCREDENTIALS structure and specify the
// path to the private key file for the current user
if (!sshClient.CreateSecurityCredentials(lpszKeyFile))
{
    sshClient.ShowError();
    return;
}

// Establish a connection with the SSH server on port 22
bConnected = sshClient.Connect(strHostName,
                               SSH_PORT_DEFAULT,
                               strUserName,
                               NULL, // No password, using a private key file
                               SSH_TIMEOUT,
                               SSH_OPTION_KEEPALIVE);

// If the connection attempt fails, then get a description of
// the error and display it in a message box
```

```
if (!bConnected)
{
    sshClient.ShowError();
    return;
}
```

In this example, the path to the private key file will be expanded to an absolute path because the USERPROFILE environment variable defines the home directory for the current user. The path must resolve to a normal file which that can be read by the current process. If the file does not exist, or it does not specify a PEM formatted file which contains an RSA or OpenSSH private key, the connection will fail and the last error code will be set to `ST_ERROR_INVALID_PRIVATE_KEY`.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

SECURITYINFO

The **SECURITYINFO** structure contains security related information about the connection, including the protocol, cipher suite and fingerprint.

```
typedef struct _SECURITYINFO
{
   DWORD        dwSize;
   DWORD        dwProtocol;
   DWORD        dwCipher;
   DWORD        dwCipherStrength;
   DWORD        dwHash;
   DWORD        dwHashStrength;
   DWORD        dwKeyExchange;
   DWORD        dwCertStatus;
   SYSTEMTIME   stCertIssued;
   SYSTEMTIME   stCertExpires;
   LPCTSTR      lpszCertIssuer;
   LPCTSTR      lpszCertSubject;
   LPCTSTR      lpszFingerprint;
} SECURITYINFO, *LPSECURITYINFO;
```

Members

dwSize

Specifies the size of the data structure. This member must always be initialized to the size of the structure in bytes prior to passing the address of this structure to the function. If this this member is not initialized, an error will be returned indicating that an invalid parameter has been passed to the function.

dwProtocol

A numeric value which specifies the protocol that was selected to establish the secure connection. One of the following values will be returned:

Value	Description
SECURITY_PROTOCOL_NONE	The connection is not secure. This value indicates a standard connection was established and all other structure members will have a value of zero.
SECURITY_PROTOCOL_SSH2	The Secure Shell 2.0 protocol was selected.

dwCipher

A numeric value which specifies the cipher that was selected when establishing the secure connection. One of the following values will be returned:

Value	Description
SECURITY_CIPHER_RC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.
SECURITY_CIPHER_DES	The DES (Data Encryption Standard) block cipher was selected. This is a fixed key length cipher, using 56-bit keys.
SECURITY_CIPHER_DES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively providing a 168-bit length key.

SECURITY_CIPHER_AES	The Advanced Encryption Standard cipher (also known as the Rijndael cipher) is a fixed block size cipher which use a key size of 128, 192 or 256 bits. This cipher is supported on Windows XP SP3 and later versions of the operating system.

dwCipherStrength

A numeric value which specifies the strength (the length of the cipher key in bits) of the cipher that was selected. Typically this value will be 128 or 256. 40-bit and 56-bit key lengths are considered weak encryption, and subject to brute force attacks. 128-bit and 256-bit key lengths are considered to be secure and are the recommended key length for secure communications.

dwHash

A numeric value which specifies the hash algorithm which was selected. One of the following values will be returned:

Value	Description
SECURITY_HASH_MD5	The MD5 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA1	The SHA-1 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA256	The SHA-256 algorithm was selected.

dwHashStrength

A numeric value which specifies the strength (the length in bits) of the message digest that was selected.

dwKeyExchange

A numeric value which specifies the key exchange algorithm which was selected. One of the following values will be returned:

Value	Description
SECURITY_KEYEX_RSA	The RSA public key algorithm was selected.
SECURITY_KEYEX_KEA	The Key Exchange Algorithm (KEA) was selected. This is an improved version of the Diffie-Hellman public key algorithm.
SECURITY_KEYEX_DH	The Diffie-Hellman key exchange algorithm was selected.
SECURITY_KEYEX_ECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography. This key exchange algorithm is only supported on Windows XP SP3 and later versions of the operating system.

dwCertStatus

This member is not used with SSH connections and will have a value of zero.

stCertIssued

This member is not used with SSH connections and will have a value of zero.

stCertExpires

This member is not used with SSH connections and will have a value of zero.

lpszCertIssuer

This member is not used with SSH connections and will have a value of zero.

lpszCertSubject

This member is not used with SSH connections and will have a value of zero.

lpszFingerprint

A null-terminated string which contains a sequence of hexadecimal values that uniquely identify the server.

Remarks

The size of this structure is typically determined using the **sizeof** operator in C/C++ and most other languages have a similar method for obtaining the size of a data structure or user-defined type. It is important to note the size of this structure will be different on 32-bit and 64-bit platforms due to the difference in the length of the structure members which are pointers.

When evaluating structure members which are string pointers, such as ***lpszCertIssuer*** and ***lpszCertSubject***, you should always check to ensure their values are not NULL (zero) before attempting to dereference them. If those values are undefined, it is not guaranteed they will point to zero-length strings.

There are additional protocols and ciphers defined which are not listed above because they are considered insecure and cannot be used when establishing a connection with the server. Although SSH protocol version 1.0 is defined in the header file, it is important to note that it is considered insecure and is no longer supported.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SSHOPTIONDATA

The **SSHOPTIONDATA** structure specifies additional option information for the client session.

```
typedef struct _SSHOPTIONDATA
{
    DWORD dwSize;
    DWORD dwReserved;
    UINT  nProxyType;
    UINT  nProxyPort;
    TCHAR szProxyHost[128];
    TCHAR szProxyUser[128];
    TCHAR szProxyPassword[128];
    UINT  nTermCols;
    UINT  nTermRows;
    TCHAR szTermName[32];
    TCHAR szCommandLine[512];
} SSHOPTIONDATA, *LPSSHOPTIONDATA;
```

Members

dwSize

An unsigned integer value which specifies the size of the SSHOPTIONDATA structure. This member must be initialized prior to passing the structure to the **Connect** method.

dwReserved

An unsigned integer value that is reserved for internal use, and should always be initialized to a value of zero.

nProxyType

An unsigned integer value that specifies the type of proxy that the client should connect through. This structure member is only used if the option SSH_OPTION_PROXYSERVER has been specified. Possible values are:

Value	Description
SSH_PROXY_NONE	No proxy server should be used when establishing the connection.
SSH_PROXY_HTTP	The connection should be established on port 80 using HTTP. An alternate port number can be specified by setting the *nProxyPort* structure member to the desired value.
SSH_PROXY_TELNET	The connection should be established on port 23 using TELNET. An alternate port number can be specified by setting the *nProxyPort* structure member to the desired value.

nProxyPort

An unsigned integer value that specifies the port number which should be used to establish the proxy connection. A value of zero specifies that the default port number appropriate for the selected protocol should be used. This structure member is only used if the option SSH_OPTION_PROXYSERVER has been specified.

szProxyHost

A null-terminated string which specifies the host name or IP address of the proxy server. This structure member is only used if the option SSH_OPTION_PROXYSERVER has been specified.

szProxyUser

A null-terminated string which specifies the user name which is used to authenticate the connection through the proxy server. This structure member is only used if the option SSH_OPTION_PROXYSERVER has been specified.

szProxyPassword

A null-terminated string which specifies the password which is used to authenticate the connection through the proxy server. This structure member is only used if the option SSH_OPTION_PROXYSERVER has been specified.

nTermCols

An unsigned integer value which specifies the number of columns for the virtual terminal allocated for the client session. The default number of columns is 80. This structure member is only used if the option SSH_OPTION_TERMINAL has been specified.

nTermRows

An unsigned integer value which specifies the number of rows for the virtual terminal allocated for the client session. The default number of rows is 25. This structure member is only used if the option SSH_OPTION_TERMINAL has been specified.

szTermName

A null-terminated string which specifies the name of the terminal emulation type. On UNIX based systems, this name typically corresponds to an entry in the terminal capability database (either termcap or terminfo). If the name is not specified, then the default name terminal name of "unknown" will be used. This structure member is only used if the option SSH_OPTION_TERMINAL has been specified.

szCommandLine

A null-terminated string which specifies the command that should be executed on the server. The output from the command is returned to the client, and the session is terminated. This structure member is only used if the option SSH_OPTION_COMMAND has been specified.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Simple Mail Transfer Protocol Class Library

Submit email messages for delivery to one or more recipients.

Reference

- Class Methods
- Data Structures
- Error Codes

Library Information

Class Name	CSmtpClient
File Name	CSMTPV12.DLL
Version	12.0.3024.1286
LibID	7EFD241B-CEB0-4667-8944-4231A1B46064
Import Library	CSMTPV12.LIB
Dependencies	None
Standards	RFC 821, RFC 1425, RFC 1869, RFC 2821

Overview

The Simple Mail Transfer Protocol (SMTP) enables applications to deliver email messages to one or more recipients. The class library provides an interface for addressing and delivering messages, and extended features such as user authentication and delivery status notification. Unlike Microsoft's Messaging API (MAPI) or Collaboration Data Objects (CDO), there is no requirement to have certain third-party email applications installed or specific types of servers installed on the local system. The CSmtpClient class can be used to deliver mail through a wide variety of systems, from standard UNIX based mail servers to Windows systems running Microsoft Exchange.

Using this class library, messages can be delivered directly to the recipient, or they can be routed through a relay server, such as an Internet service provider's mail system. The CMailMessage class can be combined with this class to provide a flexible interface for composing and delivering messages.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). You should install all updates for your development tools and have the current Windows SDK installed. The minimum supported version of Visual Studio is Visual Studio 2010 with Service Pack 1 (SP1) installed. The SocketTools header files are designed to be compatible with all modern C/C++ compilers and we also provide function definitions for several additional languages such as Object Pascal and Visual Basic.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are deploying applications to Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. If you are deploying applications to Windows 8, you must have the 8.1 update installed. If you are targeting the Windows on ARM platform, the minimum required version is Windows 10 build 1709.

SocketTools includes support for both 64-bit and 32-bit Windows platforms. All current versions of

Windows are 64-bit, and we include 32-bit x86 libraries to maintain compatibility with legacy development tools. SocketTools also provides native ARM64 libraries for systems running Windows on ARM. Note that 32-bit applications on ARM use x86 emulation, and Microsoft no longer supports native 32-bit ARM (ARM32) applications. Embarcadero's C++Builder and Delphi compilers (as of version 12.3) do not support building native ARM64 applications for Windows. For developing applications targeting the Windows on ARM platform, we recommend using Visual Studio 2019 or later.

The import libraries included with SocketTools are provided in several different formats. The most commonly used format is COFF, which is available for x64, x86 and native ARM64 platforms. For compatibility with older Borland (Embarcadero) compilers, we also provide OMF libraries for x86 platforms and ELF libraries for x64 platforms. If you are using Visual Studio, you will want to use the standard COFF import libraries. Note that some languages may not require import libraries and will link to the exported functions in the DLL based on the function declaration itself.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Simple Mail Transfer Protocol Class Methods

Class	Description
CSmtpClient	Constructor which initializes the current instance of the class
~CSmtpClient	Destructor which releases resources allocated by the class
Method	Description
AddRecipient	Add an address to the recipient list
AppendMessage	Append contents of specified file to the current message
AttachHandle	Attach the specified client handle to this instance of the class
AttachThread	Attach the specified client handle to another thread
Authenticate	Authenticate the client session with a user name and password
Cancel	Cancel the current blocking operation
CloseMessage	Close the message being composed and submit for delivery
Command	Send a command to the server
Connect	Establish a connection with a server
CreateMessage	Create a new message
CreateSecurityCredentials	Allocate a structure to establish client security credentials
DeleteSecurityCredentials	Delete the specified client security credentials
DetachHandle	Detach the handle for the current instance of this class
DisableEvents	Disable all event notification, including event callbacks
DisableTrace	Disable logging of network function calls
Disconnect	Disconnect from the current server
EnableEvents	Enable event handling by the library
EnableTrace	Enable logging of network function calls to a file
ExpandAddress	Expand the specified address
FreezeEvents	Suspend and resume event handling by the client
GetCurrentDate	Return the current date and time
GetDeliveryOptions	Return the delivery options for the current session
GetErrorString	Return a description for the specified error code
GetExtendedOptions	Return the extended options supported by the server
GetHandle	Return the client handle used by this instance of the class
GetLastError	Return the last error code
GetLocalName	Return the local host name assigned for the client session
GetResultCode	Return the result code from the previous command

GetResultString	Return the result string from the previous command
GetSecurityInformation	Return security information about the current client connection
GetStatus	Return the current status of the client
GetTimeout	Return the number of seconds until an operation times out
GetTransferStatus	Return data transfer statistics
IsBlocking	Determine if the client is blocked, waiting for information
IsConnected	Determine if the client is connected to the server
IsInitialized	Determine if the class has been successfully initialized
IsReadable	Determine if data can be read from the server
IsWritable	Determine if data can be written to the server
RegisterEvent	Register an event handler for the specified event
Reset	Reset the client and return to a command state
SendMessage	Send message to the specified recipient
SetDeliveryOptions	Set the delivery options for the current session
SetLastError	Set the last error code
SetLocalName	Set the local host name to be used for the client session
SetTimeout	Set the number of seconds until an operation times out
ShowError	Display a message box with a description of the specified error
SmtpEventProc	Process events generated by the client
SubmitMessage	Compose and submit a message for delivery to the specified mail server
VerifyAddress	Verify that the specified address is valid
Write	Write data to the server

CSmtpClient::CSmtpClient Method

```
CSmtpClient();
```

The **CSmtpClient** constructor initializes the class library and validates the license key at runtime.

Remarks

If the constructor fails to validate the runtime license, subsequent methods in this class will fail. If the product is installed with an evaluation license, then the application will only function on the development system and cannot be redistributed.

The constructor calls the **SmtpInitialize** function to initialize the library, which dynamically loads other system libraries and allocates thread local storage. If you are using this class within another DLL, it is important that you do not create or destroy an instance of the class from within the **DllMain** function because it can result in deadlocks or access violation errors. You should not declare static or global instances of this class within another DLL if it is linked with the C runtime library (CRT) because it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

~CSmtpClient, IsInitialized

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSmtpClient::~CSmtpClient

```
~CSmtpClient();
```

The **CSmtpClient** destructor releases resources allocated by the current instance of the **CSmtpClient** object. It also uninitializes the library if there are no other concurrent uses of the class.

Remarks

When a **CSmtpClient** object goes out of scope, the destructor is automatically called to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all handles that were created for the client session are destroyed.

The destructor is not called explicitly by the application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CSmtpClient

CSmtpClient::AddRecipient Method

```
INT AddRecipient(
   LPCTSTR lpszAddress
);
```

The **AddRecipient** method adds the specified address to the recipient list for the current message. This method should be called once for each recipient.

Parameters

lpszAddress

Points to a string which specifies the address to be added to the recipient list.

Return Value

If the method succeeds, the return value is the server result code. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CloseMessage, CreateMessage, ExpandAddress, VerifyAddress

CSmtpClient::AppendMessage Method

```
INT AppendMessage(
   LPCTSTR lpszFileName
);

INT AppendMessage(
   LPBYTE lpMessage,
   DWORD dwMessageSize
);

INT AppendMessage(
   HGLOBAL hgblMessage,
   DWORD dwMessageSize
);
```

The **AppendMessage** method writes the contents of a specified file or buffer to the data stream, appending it to the current message contents.

Parameters

lpszFileName

A null-terminated string which specifies the name of a file. The contents of the file are appended to the current message being submitted to the mail server for delivery.

lpMessage

Pointer to a buffer which contains the message data to be appended to the current message.

hgblMessage

A global memory handle which references data that is to be appended to the current message.

dwMessageSize

An unsigned integer which specifies the length of the message in bytes.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **AppendMessage** method is used to append the contents of a file, memory buffer, or global memory handle to the current message that is being composed for delivery. To send a complete RFC 822 formatted message, refer to the **SendMessage** method.

This method will cause the current thread to block until the complete message has been written, a timeout occurs or the operation is canceled. During the transfer, the SMTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **EnableEvents**, or by registering a callback function using the **RegisterEvent** method.

To determine the current status of a transfer while it is in progress, use the **GetTransferStatus** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CloseMessage, CreateMessage, SendMessage

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSmtpClient::AttachHandle Method

```
VOID AttachHandle(
   HCLIENT hClient
);
```

The **AttachHandle** method attaches the specified client handle to the current instance of the class.

Parameters

hClient

The handle to the client session that will be attached to the current instance of the class object.

Return Value

None.

Remarks

This method is used to attach a client handle created outside of the class using the SocketTools API. Once the client handle is attached to the class, the other class member functions may be used with that client session.

If a client handle has already been created for the class, that handle will be released when the new handle is attached to the class object. If you want to prevent the previous client session from being terminated, you must call the **DetachHandle** method. Failure to release the detached handle may result in a resource leak in your application.

Note that the ***hClient*** parameter is presumed to be a valid client handle and no checks are performed to ensure that the handle is valid. Specifying an invalid client handle will cause subsequent method calls to fail.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

See Also

AttachThread, DetachHandle, GetHandle

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSmtpClient::AttachThread Method

```
DWORD AttachThread(
   DWORD dwThreadId
);
```

The **AttachThread** method attaches the specified client handle to another thread.

Parameters

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the method succeeds, the return value is the thread ID of the previous owner. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

When a client handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in a client application to create the client handle, and then pass that handle to another worker thread. The **AttachThread** method can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the method, the original owner of the handle can be restored before the worker thread terminates.

This method should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **AttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **Cancel** method and then release the handle after the blocking method exits and control is returned to the current thread.

Note that the ***dwThreadId*** parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the client handle used by the class until the destructor is called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

CSmtpClient::Authenticate Method

```
INT Authenticate(
   LPCTSTR lpszUserName,
   LPCTSTR lpszPassword,
   UINT nAuthType
);
```

The **Authenticate** method provides client authentication information to the server.

Parameters

lpszUserName

A null-terminated string which specifies the account name for the user authorized to send mail through the server.

lpszPassword

A null-terminated string which specifies the password to be used when authenticating the current client session. If you are using the SMTP_AUTH_XOAUTH2 or SMTP_AUTH_BEARER authentication methods, this parameter is not a password, instead it specifies the bearer token provided by the mail service.

nAuthType

An integer value which specifies which method the library should use to authenticate the client session. This parameter should be set to one of the following values:

Value	Description
SMTP_AUTH_LOGIN	The client will authenticate using the AUTH LOGIN command. This encodes the username and password, however the credentials are not encrypted and it is recommended you use a secure connection. This is the default method accepted by most mail servers and is the preferred authentication type for most clients.
SMTP_AUTH_PLAIN	The client will authenticate using the AUTH PLAIN command. This encodes the username and password, however the credentials are not encrypted and it is recommended you use a secure connection. The server must support the PLAIN Simple Authentication and Security Layer (SASL) mechanism as defined in RFC 4616.
SMTP_AUTH_XOAUTH2	The client will authenticate using the AUTH XOAUTH2 command. This authentication method does not require the user password, instead the ***lpszPassword*** parameter must specify the bearer token issued by the service provider. The application must provide a valid access token which has not expired, or this method will fail.
SMTP_AUTH_BEARER	The client will authenticate using the AUTH OAUTHBEARER command as defined in RFC 7628. This authentication method does not require the user password, instead the ***lpszPassword*** parameter must specify the bearer token issued by the service provider. The application must provide a valid access token which has not expired, or this method will fail.

Return Value

If the method succeeds, the return value is the command result code. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

To submit a mail message for delivery, virtually all public mail servers require clients to authenticate and will only accept messages from authorized users. In some cases, they may also require the sender email address match the account being used to authenticate the session. It is also typical for most public mail servers to reject authentication attempts over a standard (non-secure) connection. You should always use a secure connection whenever possible.

All authentication methods require the mail server to support the standard service extensions for authentication as specified in the RFC 4954. The server must support the ESMTP protocol extensions and the AUTH command. A user name and password are required for authentication. If you wish to authenticate without a user password, you must use one of the OAuth 2.0 authentication methods.

If the *nAuthType* parameter is omitted, it will default to using SMTP_AUTH_LOGIN and this is accepted by most mail servers. It is common for mail servers to allow the SMTP_AUTH_PLAIN method as well, however it is recommended you explicitly check whether the server supports the desired authentication method by calling the **GetExtendedOptions** method. If you attempt to use an authentication type which is not supported by the server, this method will fail and the last error code will be set to ST_ERROR_INVALID_AUTHENTICATION_TYPE.

You should only use an OAuth 2.0 authentication method if you understand the process of how to request the access token. Obtaining an access token requires registering your application with the mail service provider (e.g.: Microsoft or Google), getting a unique client ID associated with your application and then requesting the access token using the appropriate scope for the service. Obtaining the initial token will typically involve interactive confirmation on the part of the user, requiring they grant permission to your application to access their mail account.

The SMTP_AUTH_XOAUTH2 and SMTP_AUTH_BEARER authentication methods are similar, but they are not interchangeable. Both use an OAuth 2.0 bearer token to authenticate the client session, but they differ in how the token is presented to the server. It is currently preferable to use the XOAUTH2 method because it is more widely available and some service providers do not yet support the OAUTHBEARER method.

Your application should not store an OAuth 2.0 bearer token for later use. They have a relatively short lifespan, typically about an hour, and are designed to be used with that session. You should specify offline access as part of the OAuth 2.0 scope if necessary and store the refresh token provided by the service. The refresh token has a much longer validity period and can be used to obtain a new bearer token when needed.

Example

```
DWORD dwOptions = 0;

// Determine which extended options and authentication methods
// are supported by this server

BOOL bExtended = pClient->GetExtendedOptions(&dwOptions);

if (bUseBearerToken)
{
    if (bExtended && (dwOptions & SMTP_EXTOPT_XOAUTH2))
```

```
    {
        INT nResult = pClient->Authenticate(lpszUserName, lpszBearerToken,
SMTP_AUTH_XOAUTH2);

        if (nResult == SMTP_ERROR)
        {
            // An error occurred during authentication; when using an
            // OAuth 2.0 bearer token, this typically means that the token
            // has expired and must be refreshed
            return;
        }
    }
    else
    {
        // The server does not support XOAUTH2
        return;
    }
}
else
{
    if (bExtended && (dwOptions & SMTP_EXTOPT_AUTHLOGIN))
    {
        INT nResult = pClient->Authenticate(lpszUserName, lpszPassword);

        if (nResult == SMTP_ERROR)
        {
             // An error occurred during authentication
            return;
        }
    }
    else
    {
         // The server does not support AUTH LOGIN
        return;
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

Connect, GetExtendedOptions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSmtpClient::Cancel Method

```
INT Cancel();
```

The **Cancel** method cancels any outstanding blocking operation in the client, causing the blocking method to fail. The application may then retry the operation or terminate the client session.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

When the **Cancel** method is called, the blocking method will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

See Also

IsBlocking

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSmtpClient::CloseMessage Method

```
INT CloseMessage();
```

The **CloseMessage** method ends the composition of the current message. The server then queues the message for delivery to each recipient specified by the client.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **CloseMessage** method should be called after all of the message data has been written to the data stream.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

AppendMessage, CreateMessage, Write

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSmtpClient::Command Method

```
INT Command(
   LPCTSTR lpszCommand,
   LPCTSTR lpszParameter
);
```

The **Command** method sends a command to the server, and returns the result code back to the caller. This method is typically used for site-specific commands not directly supported by the API.

Parameters

lpszCommand

The command which will be executed by the server.

lpszParameter

An optional command parameter. If the command requires more than one parameter, then they should be combined into a single string, with a space separating each parameter. If the command does not accept any parameters, this value may be NULL.

Return Value

If the command was successful, the method returns the result code. If the command failed, the method returns SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

A list of valid commands can be found in the technical specification for the protocol. Many servers will list supported commands when the HELP command is used.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

CSmtpClient::Connect Method

```
BOOL Connect(
   LPCTSTR lpszRemoteHost,
   UINT nRemotePort,
   UINT nTimeout,
   DWORD dwOptions
);
```

The **Connect** method is used to establish a connection with the server.

Parameters

lpszRemoteHost

The name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on. A value of zero specifies that the default port number should be used. For standard connections, the default port number is 25. An alternative port is 587, which is commonly used by authenticated clients to submit messages for delivery. For implicit TLS connections, the default port number is 465.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
SMTP_OPTION_NONE	No additional options are specified when establishing a connection with the server. A standard, non-secure connection will be used and the client will not attempt to use extended (ESMTP) features of the protocol. Note that if the mail server requires authentication, the SMTP_OPTION_EXTENDED option must be specified.
SMTP_OPTION_EXTENDED	Extended SMTP commands should be used if possible. This option enables features such as authentication and delivery status notification. If this option is not specified, the library will not attempt to use any extended features. This option is automatically enabled if the connection is established on port 587 because submitting messages for delivery using this port typically requires client authentication.
SMTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number,

	default capability selection and how the connection is established.
SMTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
SMTP_OPTION_SECURE	This option specifies that a secure connection should be established with the server and requires that the server support the TLS protocol. The client will initiate the secure session using the STARTTLS command.
SMTP_OPTION_SECURE_IMPLICIT	This option specifies the client should attempt to establish a secure connection with the server. The server must support secure connections using the TLS protocol, and the secure session must be negotiated immediately after the connection has been established.
SMTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
SMTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
SMTP_OPTION_FREETHREAD	This option specifies that this instance of the class may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the class instance is synchronized across multiple threads.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method will block the current thread until a connection has been established or the timeout period has elapsed. To prevent it from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling the **Connect** method in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each connection.

The *dwOptions* argument can be used to specify the threading model that is used by the library when

a connection is established. By default, the class instance is initially attached to the thread that created it. From that point on, until the handle is released, only the owner may call methods using that instance of the class. The ownership of the class instance may be transferred from one thread to another using the **AttachThread** method.

Specifying the SMTP_OPTION_FREETHREAD option enables any thread to call any method in that instance of the class, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the class instance is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same instance.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

CSmtpClient::CreateMessage Method

```
INT CreateMessage(
   LPCTSTR lpszSender,
   DWORD dwMessageSize
);
```

The **CreateMessage** method creates a new message for delivery.

Parameters

lpszSender

A null-terminated string which specifies the email address of the user sending the message. This typically corresponds to the address in the From header of the message, but it is not required that they be the same.

dwMessageSize

An unsigned integer which specifies the size of the message in bytes. If the size of the message is unknown, this value should be zero. This parameter is ignored if the server does not support extended features. If the message size is larger than what the server will accept, this method will fail. Most Internet Service Providers impose a limit on the size of an email message, typically between 5 and 10 megabytes.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **CreateMessage** method begins the composition of a new message to be submitted to the mail server for delivery. There are several steps that must be followed when dynamically composing a message for delivery:

1. Call the **CreateMessage** method to begin the message composition. The sender email address should generally be the same address as the one used in the "From" header field in the message.
2. Call the **AddRecipient** method for each recipient of the message. These addresses are typically specified in the "To" and "Cc" header fields in the message. Additional addresses may also be be provided which are not specified in the email message itself. This is how one or more blind carbon copies of a message is delivered. Most servers have a limit on the total number of recipients that may be specified for a single message. This limit is usually around 100 addresses.
3. Call the **Write** method to write the contents of the message to the data stream. The application may also choose to use the **AppendMessage** method to write out a large amount of message data, or write the contents of a file to the data stream.
4. Call the **CloseMessage** method to close the message and submit it to the mail server for delivery.

For applications that do not need to dynamically compose the message and already have the message contents stored in a file or memory buffer, the **SendMessage** method is the preferred method of submitting a message for delivery.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

CSmtpClient::CreateSecurityCredentials Method

```
BOOL CreateSecurityCredentials(
   DWORD dwProtocol,
   DWORD dwOptions,
   LPCTSTR lpszUserName,
   LPCTSTR lpszPassword,
   LPCTSTR lpszCertStore,
   LPCTSTR lpszCertName
);

BOOL CreateSecurityCredentials(
   LPCTSTR lpszCertStore,
   LPCTSTR lpszCertName
);

BOOL CreateSecurityCredentials(
   LPCTSTR lpszCertName
);
```

The **CreateSecurityCredentials** method creates security credentials for the client session.

Parameters

dwProtocol

A bitmask of supported security protocols. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_TLS	Either the TLS 1.2 or 1.3 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers which reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows

	Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwOptions

A value which specifies one or more options. This member is constructed by using a bitwise operator with any of the following values:

Value	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

lpszUserName

A null-terminated string which specifies the certificate owner's username. A value of NULL specifies that no username is required. Currently this parameter is not used and any value specified will be ignored.

lpszPassword

A null-terminated string which specifies the certificate owner's password. A value of NULL specifies that no password is required. This parameter is only used if a PKCS #12 (PFX) certificate file is specified and that certificate has been secured with a password. This value will be ignored the current user or local machine certificate store is specified.

lpszCertStore

A null-terminated string which specifies the name of the certificate store to open. A certificate store

is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A null-terminated string which specifies the name of the certificate to use. The method will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the method will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the method will return an error indicating that the certificate could not be found.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

A client application only needs to call this method if the server requires that the client provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The ***dwOptions*** parameter should be set to CREDENTIAL_STORE_FILENAME and the ***lpszCertStore*** parameter should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS #12.These certificate files typically have an extension of .pfx or .p12. If a password was specified when the certificate was

created, it must be provided in the *lpszPassword* parameter or the library will be unable to access the certificate.

Note that the *lpszUserName* and *lpszPassword* parameters are optional values which are used to access the certificate store or client certificate. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session. In most cases, these parameters can be NULL or omitted.

Example

```
pClient->CreateSecurityCredentials(
            SECURITY_PROTOCOL_DEFAULT,
            0,
            NULL,
            NULL,
            lpszCertStore,
            lpszCertName);

bConnected = pClient->Connect(lpszHostName,
                              SMTP_PORT_SECURE,
                              SMTP_TIMEOUT,
                              SMTP_OPTION_SECURE);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CSmtpClient::DeleteSecurityCredentials Method

```
VOID DeleteSecurityCredentials();
```

The **DeleteSecurityCredentials** method releases the security credentials for the current session.

Parameters

None.

Return Value

None.

Remarks

This method can be used to release the memory allocated to the client or server credentials after a secure connection has been terminated. The security credentials are released when the class destructor is called, so it is normally not required that the application explicitly call this method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CreateSecurityCredentials

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSmtpClient::DetachHandle Method

```
HCLIENT DetachHandle();
```

The **DetachHandle** method detaches the client handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the client handle associated with the current instance of the class object. If there is no active client session, the value INVALID_CLIENT will be returned.

Remarks

This method is used to detach a client handle created by the class for use with the SocketTools API. Once the client handle is detached from the class, no other class member functions may be called. Note that the handle must be explicitly released at some later point by the process or a resource leak will occur.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

AttachHandle, GetHandle

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSmtpClient::DisableEvents Method

```
INT DisableEvents();
```

The **DisableEvents** method disables the event notification mechanism, preventing subsequent event notification messages from being posted to the application's message queue.

This method has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **DisableEvents** method is used to disable event message posting for the specified client session. Although this will immediately prevent any new events from being generated, it is possible that messages could be waiting in the message queue. Therefore, an application must be prepared to handle client event messages after this method has been called.

This method is automatically called if the client has event notification enabled, and the **Disconnect** method is called. The same issues regarding outstanding event messages also applies in this situation, requiring that the application handle event messages that may reference a client handle that is no longer valid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

See Also

EnableEvents, RegisterEvent

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSmtpClient::DisableTrace Method

```
BOOL DisableTrace();
```

The **DisableTrace** method disables the logging of network function calls.

Parameters

None.

Remarks

This method will disable output to the log file for the current thread or process, depending on the flags used when logging was enabled. If this method is not called, the resources that were allocated for the logging session will be released when the process ends.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, a value of zero is returned.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

See Also

EnableTrace

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSmtpClient::Disconnect Method

```
VOID Disconnect();
```

The **Disconnect** method terminates the connection with the server, closing the socket and releasing the memory allocated for the client session.

Parameters

None.

Return Value

None.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

See Also

Connect, IsConnected

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSmtpClient::EnableEvents Method

```
INT EnableEvents(
   HWND hEventWnd,
   UINT uEventMsg
);
```

The **EnableEvents** method enables event notifications using Windows messages.

This method has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Applications should use the **RegisterEvent** method to register an event handler which is invoked when an event occurs.

Parameters

hEventWnd

Handle to the window which will receive the client notification messages. This parameter must specify a valid window handle. If a NULL handle is specified, event notification will be disabled.

uEventMsg

The message that is received when a client event occurs. This value must be greater than 1024.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **EnableEvents** method is used to request that notification messages be posted to the specified window whenever a client event occurs. This allows an application to monitor the status of different client operations, such as a file transfer.

The *wParam* argument will contain the client handle, the low word of the *lParam* argument will contain the event ID, and the high word will contain any error code. If no error has occurred, the high word will always have a value of zero. The following events may be generated:

Value	Description
SMTP_EVENT_CONNECT	The connection to the server has completed. The high word of the *lParam* parameter should be checked, since this notification message will be posted if an error has occurred.
SMTP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
SMTP_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
SMTP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This

	event is only generated if the client is in asynchronous mode.
SMTP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
SMTP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
SMTP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.
SMTP_EVENT_PROGRESS	The client is in the process of sending or receiving a file on the data channel. This event is called periodically during a transfer so that the client can update any user interface components such as a status control or progress bar.

It is not required that the client be placed in asynchronous mode in order to receive command and progress event notifications. To disable event notification, call the **DisableEvents** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

See Also

DisableEvents, RegisterEvent

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSmtpClient::EnableTrace Method

```
BOOL EnableTrace(
   LPCTSTR lpszTraceFile,
   DWORD dwTraceFlags
);
```

The **EnableTrace** method enables the logging of network function calls to a file.

Parameters

lpszTraceFile

A null-terminated string which specifies the name of the logfile which will be appended to or created. It is recommended that this file always specify an absolute path to avoid any ambiguity. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
TRACE_INFO	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
TRACE_ERROR	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
TRACE_HEXDUMP	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
TRACE_TRUNCATE	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for

	multithreaded applications that are using worker threads.

Return Value

If the method succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the log file cannot be created.

Remarks

Logging is enabled and disabled at the thread or process level, depending on the flags passed to this method, and is not associated with a specific class instance. When logging is enabled, the information is appended to the specified file. If the file does not exist, it will be created. To limit the size of the file, enable and disable logging only around those sections of code that you wish to debug. If you do not provide a full path to the file, it will be relative to the current working directory for the process. This can produce unexpected results in multithreaded applications because the current directory is global to the entire process and can be changed by any thread at any time.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

The TRACE_HEXDUMP option can generate very large files because it includes all of the data exchanged between your application and the remote host. The TRACE_TRUNCATE option is only evaluated when logging is first enabled for a thread or process. If logging is already active, specifying this option will have no effect.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "**0x**". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxxx:xxxx::xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, a connection is being made to a system with the IPv4 address 192.0.0.1 on port 1234.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

DisableTrace

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSmtpClient::ExpandAddress Method

```
INT ExpandAddress(
   LPCTSTR lpszMailingList,
   LPTSTR lpszAddresses,
   INT nMaxLength
);

INT ExpandAddress(
   LPCTSTR lpszMailingList,
   CString& strAddresses
);
```

The **ExpandAddress** method expands the specified mailing list, returning the membership of that list.

Parameters

lpszMailingList

Points to a string which specifies the mailing list that the server should expand into full addresses.

lpszAddresses

Points to a buffer that the expanded addresses will be copied into. This argument may also be a **CString** object which will contain the expanded addresses when the method returns.

nMaxLength

Maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the method succeeds, the return value is the server result code. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **ExpandAddress** method requests that the server expand the specified email address. Typically this is used to expand aliases which refer to a mailing list, returning all of the members of that list. A server may not support this command, or may restrict its usage. An application should not depend on the ability to expand addresses.

This method cannot be called while a mail message is being composed.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

AddRecipient, VerifyAddress

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSmtpClient::FreezeEvents Method

```
INT FreezeEvents(
   BOOL bFreeze
);
```

The **FreezeEvents** method is used to suspend and resume event handling by the client.

Parameters

bFreeze

A non-zero value specifies that event handling should be suspended by the client. A zero value specifies that event handling should be resumed.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

This method should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all client events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if the client has suspended event handling, and four read events occur, once event handling is resumed only one of those read events will be posted to the client. This prevents the application from being flooded by a potentially large number of queued events.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CSmtpClient::GetCurrentDate Method

```
INT GetCurrentDate(
   LPTSTR lpszDateString,
   INT nMaxLength
);

INT GetCurrentDate(
   CString& strDateString
);
```

The **GetCurrentDate** method copies the current date and time to the specified buffer in a format that is commonly used in mail messages. This date format should be used in all date-related fields in the message header.

Parameters

lpszDateString

Pointer to a string buffer that will contain the current date and time when the method returns. This argument may also be a **CString** object.

nMaxLength

The maximum number of characters that can be copied into the string buffer.

Return Value

If the method succeeds, the return value is the number of characters copied into the buffer, not including the null-terminator. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The date value that is returned is adjusted for the local timezone.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

CloseMessage, CreateMessage

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSmtpClient::GetDeliveryOptions Method

```
BOOL GetDeliveryOptions(
   LPDWORD lpdwOptions
);
```

The **GetDeliveryOptions** method returns the delivery status notification options for the current session.

Parameters

lpdwOptions

Address of a variable that will be set to the current delivery options. This bitmask is created by combining one or more of the following values with a bitwise Or operator:

Value	Description
SMTP_NOTIFY_NEVER	Never return information about the success or failure of the message delivery process.
SMTP_NOTIFY_SUCCESS	Return a message to the sender if the message has been successfully delivered to the recipient's mail server.
SMTP_NOTIFY_FAILURE	Return a message to the sender if the message could not be delivered to the recipient's mail server.
SMTP_NOTIFY_DELAY	Return a message to the sender if delivery of the message was delayed.
SMTP_RETURN_HEADERS	Return only the message headers to the sender.
SMTP_RETURN_MESSAGE	Return the complete message headers and body to the sender.

Return Value

If the method succeeds, the return value is a non-zero value. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetDeliveryOptions** method returns the current delivery options for the client session. Note that delivery options are only available on those mail servers which support delivery status notification (DSN) using the extended SMTP protocol. The client must connect specifying SMTP_OPTION_EXTENDED in order to use extended server options.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

See Also

CSmtpClient::GetErrorString Method

```
INT GetErrorString(
   DWORD dwErrorCode,
   LPTSTR lpszDescription,
   INT nMaxLength
);

INT GetErrorString(
   DWORD dwErrorCode,
   CString& strDescription
);
```

The **GetErrorString** method is used to return a description of a specific error code. Typically this is used in conjunction with the **GetLastError** method for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

The buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length. An alternate form of the method accepts a **CString** variable which will contain the error description.

nMaxLength

The maximum number of characters that may be copied into the description buffer.

Return Value

If the method succeeds, the return value is the length of the description string. If the method fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the method is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

CSmtpClient::GetExtendedOptions Method

```
BOOL GetExtendedOptions(
   LPDWORD lpdwOptions
);
```

The **GetExtendedOptions** method returns the extended server options for the current session.

Parameters

lpdwOptions

Address of a variable that will be set to the current server options. This bitmask is created by combining one or more of the following values with a bitwise Or operator:

Value	Description
SMTP_EXTOPT_EXPN	The server supports address expansion using the EXPN command. The **ExpandAddress** method can be used to expand addresses, which typically returns the email addresses associated with a mailing list. Most public mail servers restrict or disable this functionality because it can present a security risk. If a server does permit the use of the command, it is often limited to specific authorized users.
SMTP_EXTOPT_VRFY	The server supports verification of addresses using the VRFY command. The **VerifyAddress** method can be used to verify addresses. Most public mail servers restrict the ability for clients to verify email addresses to prevent potential abuse. If a server does permit the use of the command, it is often limited to specific authorized users.
SMTP_EXTOPT_DSN	The server supports delivery status notification (DSN) which allows the sender to be notified when a message has been delivered, or when an error occurs during the delivery process. The **SetDeliveryOptions** method can be used to specify the delivery options to be used in the current session.
SMTP_EXTOPT_SIZE	The server supports the use of the SIZE parameter, which enables the client to determine the maximum message size that may be delivered through the server. Most public mail servers impose a limit of on the total size of a message, including any encoded attachments.
SMTP_EXTOPT_ETRN	The server supports the use of the ETRN command, instructing the server to start processing its message queues for a specific host. Most public mail servers do not support this capability and its use has been deprecated.
SMTP_EXTOPT_8BITMIME	The server supports the delivery of messages that contain characters with the high bit set. Most servers support this option, however it is recommended that you encode any message text which contains non-ASCII characters to ensure the broadest compatibility with other servers and clients.
SMTP_EXTOPT_STARTTLS	The server supports explicit TLS sessions. This extended option

	is used internally to determine how secure connections should be established, and if a secure connection can be made using the standard submission port.
SMTP_EXTOPT_UTF8	The server supports UTF-8 encoding in email addresses and the message envelope. Not all mail servers will have this extended capability enabled, and applications should not depend on being able to provide internationalized user and domain names unless this option bit flag has been set.

In addition, there are extended options which specify the authentication methods supported by the server. A server will typically support multiple authentication methods and may be one or more of the following values:

Value	Description
SMTP_EXTOPT_AUTHLOGIN	The server supports client authentication using the AUTH LOGIN command. This is the default authentication method and is supported by most mail servers. The user name and password are encoded in a specific format, but are not encrypted. The client should use a secure connection whenever possible.
SMTP_EXTOPT_AUTHPLAIN	The server supports client authentication using the AUTH PLAIN command. The use name and password are encoded in a specific format, but are not encrypted. If a server supports this authentication method, it is very likely it also supports AUTH LOGIN. It is recommended you use only use AUTH PLAIN authentication if the server does not support AUTH LOGIN.
SMTP_EXTOPT_XOAUTH2	The server supports client authentication using AUTH XOAUTH2 command. Instead of a password, an OAuth 2.0 bearer token is used to authenticate the user which previously authorized access to the mail server using their account information. The connection must be secure to use this authentication method.
SMTP_EXTOPT_BEARER	The server supports client authentication using AUTH OAUTHBEARER command as specified in RFC 7628. Instead of a password, an OAuth 2.0 bearer token is used to authenticate the user which previously authorized access to the mail server using their account information. The connection must be secure to use this authentication method. The connection must be secure to use this authentication method.

Return Value

If the method succeeds, the return value is a non-zero value. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetExtendedOptions** method returns the extended options supported by the server. The use of

extended options requires that the server support the ESMTP protocol, and that the client connect using the SMTP_OPTION_EXTENDED option.

You should check these options prior to calling **Authenticate** to determine which authentication methods are acceptable to the server. If you wish to use an OAuth 2.0 bearer token, always check to make sure either the SMTP_EXTOPT_XOAUTH2 or SMTP_EXTOPT_BEARER bit flags are set in the options value returned by this method.

Example

```
BOOL bExtended = FALSE;
DWORD dwOptions = 0;

// Determine which extended options and authentication methods
// are supported by this server

bExtended = pClient->GetExtendedOptions(&dwOptions);

if (bExtended && (dwOptions & SMTP_EXTOPT_XOAUTH2))
{
    INT nResult = pClient->Authenticate(lpszUserName, lpszBearerToken,
SMTP_AUTH_XOAUTH2);

    if (nResult == SMTP_ERROR)
    {
        // An error occurred during authentication; when using an
        // OAuth 2.0 bearer token, this typically means that the token
        // has expired and must be refreshed
        return;
    }
}
else
{
    // The server does not support XOAUTH2
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

CSmtpClient::GetHandle Method

```
HCLIENT GetHandle();
```

The **GetHandle** method returns the client handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the client handle associated with the current instance of the class object. If there is no active client session, the value INVALID_CLIENT will be returned.

Remarks

This method is used to obtain the client handle created by the class for use with the SocketTools API.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

CSmtpClient::GetLastError Method

```
DWORD GetLastError();

DWORD GetLastError(
   CString& strDescription
);
```

Parameters

strDescription

A string which will contain a description of the last error code value when the method returns. If no error has been set, or the last error code has been cleared, this string will be empty.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **SetLastError** method. The Return Value section of each reference page notes the conditions under which the method sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **GetLastError** method immediately when a method's return value indicates that an error has occurred. That is because some methods call **SetLastError**(0) when they succeed, clearing the error code set by the most recently failed method.

Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or SMTP_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

The description of the error code is the same string that is returned by the **GetErrorString** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

CSmtpClient::GetLocalName Method

```
INT GetLocalName(
   LPTSTR lpszLocalName,
   INT nMaxLength
);

INT GetLocalName(
   CString& strLocalName
);
```

The **GetLocalName** method returns the local domain name used to identify the client to the mail server.

Parameters

lpszLocalName

The buffer that will contain the local domain name as a string. This may also be a **CString** object which will contain the domain name when the method returns.

nMaxLength

The maximum number of characters that may be copied into the string buffer.

Return Value

If the method succeeds, the return value is the length of the domain name string. If the method fails, the return value is zero, meaning that no local domain name has been specified for this client session.

Remarks

If no local domain name has been explicitly set, then the client will use the default domain name for the local host as configured in the operating system. Note that this is not a general purpose method which can be used to determine the domain name that as been assigned to the local host. It will only return the local domain name set by a previous call to the **SetLocalName** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CSmtpClient::GetResultCode Method

```
INT GetResultCode();
```

The **GetResultCode** method reads the result code returned by the server in response to a command. The result code is a three-digit numeric code, and indicates if the operation succeeded, failed or requires additional action by the client.

Parameters

None.

Return Value

If the method succeeds, the return value is the result code. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

Result codes are three-digit numeric values returned by the server. They may be broken down into the following ranges:

Value	Description
100-199	Positive preliminary result. This indicates that the requested action is being initiated, and the client should expect another reply from the server before proceeding.
200-299	Positive completion result. This indicates that the server has successfully completed the requested action.
300-399	Positive intermediate result. This indicates that the requested action cannot complete until additional information is provided to the server.
400-499	Transient negative completion result. This indicates that the requested action did not take place, but the error condition is temporary and may be attempted again.
500-599	Permanent negative completion result. This indicates that the requested action did not take place.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

See Also

Command, GetResultString

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSmtpClient::GetResultString Method

```
INT GetResultString(
   LPTSTR lpszResult,
   INT cbResult
);

INT GetResultString(
   CString& strResult
);
```

The **GetResultString** method returns the last message sent by the server along with the result code.

Parameters

lpszResult

The buffer that will contain the result string returned by the server. An alternate form of the method accepts a **CString** argument which will contain the result string returned by the server.

cbResult

The maximum number of characters that may be copied into the result string buffer, including the terminating null character.

Return Value

If the method succeeds, the return value is the length of the result string. If a value of zero is returned, this means that no result string was sent by the server. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetResultString** method is most useful when an error occurs because the server will typically include a brief description of the cause of the error. This can then be parsed by the application or displayed to the user. The result string is updated each time the client sends a command to the server and then calls **GetResultCode** to obtain the result code for the operation.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

Command, GetResultCode

CSmtpClient::GetSecurityInformation Method

```
BOOL GetSecurityInformation(
   LPSECURITYINFO lpSecurityInfo
);
```

The **GetSecurityInformation** method returns security protocol, encryption and certificate information about the current client connection.

Parameters

lpSecurityInfo

A pointer to a SECURITYINFO structure which contains information about the current client connection. The *dwSize* member of this structure must be initialized to the size of the structure before passing the address of the structure to this method.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method is used to obtain security related information about the current client connection to the server. It can be used to determine if a secure connection has been established, what security protocol was selected, and information about the server certificate. Note that a secure connection has not been established, the *dwProtocol* structure member will contain the value SECURITY_PROTOCOL_NONE.

Example

```
// Notifies the user if the connection is secure or not
SECURITYINFO securityInfo;
securityInfo.dwSize = sizeof(SECURITYINFO);

if (pClient->GetSecurityInformation(&securityInfo))
{
    if (securityInfo.dwProtocol == SECURITY_PROTOCOL_NONE)
    {
        MessageBox(NULL, _T("The connection is not secure"),
                         _T("Connection"), MB_OK);
    }
    else
    {
        if (securityInfo.dwCertStatus == SECURITY_CERTIFICATE_VALID)
        {
            MessageBox(NULL, _T("The connection is secure"),
                             _T("Connection"), MB_OK);
        }
        else
        {
            MessageBox(NULL, _T("The server certificate not valid"),
                             _T("Connection"), MB_OK);
        }
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

Connect, CreateSecurityCredentials, SECURITYINFO

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSmtpClient::GetStatus Method

```
INT GetStatus();
```

The **GetStatus** method the current status of the client session.

Parameters

None.

Return Value

If the method succeeds, the return value is the client status code. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetStatus** method returns a numeric code which identifies the current state of the client session. The following values may be returned:

Value	Description
SMTP_STATUS_UNUSED	No connection has been established.
SMTP_STATUS_IDLE	The client is current idle and not sending or receiving data.
SMTP_STATUS_CONNECT	The client is establishing a connection with the server.
SMTP_STATUS_READ	The client is reading data from the server.
SMTP_STATUS_WRITE	The client is writing data to the server.
SMTP_STATUS_DISCONNECT	The client is disconnecting from the server.

In a multithreaded application, any thread in the current process may call this method to obtain status information for the specified client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

See Also

IsBlocking, IsConnected, IsInitialized, IsReadable, IsWritable

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSmtpClient::GetTimeout Method

```
INT GetTimeout();
```

The **GetTimeout** method returns the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the method will fail and return to the caller.

Parameters

None.

Return Value

If the method succeeds, the return value is the timeout period in seconds. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The timeout value is only used with blocking client connections. A value of zero indicates that the default timeout period of 20 seconds should be used.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

See Also

Connect, IsReadable, IsWritable, Read, SetTimeout, Write

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSmtpClient::GetTransferStatus Method

```
INT GetTransferStatus(
   HCLIENT hClient,
   LPSMTPTRANSFERSTATUS lpStatus
);
```

The **GetTransferStatus** method returns information about the message being submitted to the mail server.

Parameters

hClient

Handle to the client session.

lpStatus

A pointer to an SMTPTRANSFERSTATUS structure which contains information about the status of the message being submitted for delivery.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetTransferStatus** method returns information about the current message being submitted, including the average number of bytes transferred per second and the estimated amount of time until the transfer completes. If there is no message currently being submitted, this method will return the status of the last successful submission made by the client.

In a multithreaded application, any thread in the current process may call this method to obtain the status of a submission for the specified client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

EnableEvents, GetStatus, RegisterEvent

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSmtpClient::IsBlocking Method

```
BOOL IsBlocking();
```

The **IsBlocking** method is used to determine if the client is currently performing a blocking operation.

Parameters

None.

Return Value

If the client is performing a blocking operation, the method returns a non-zero value. If the client is not performing a blocking operation, or the client handle is invalid, the method returns zero.

Remarks

Because a blocking operation can allow the application to be re-entered (for example, by pressing a button while the operation is being performed), it is possible that another blocking method may be called while it is in progress. Since only one thread of execution may perform a blocking operation at any one time, an error would occur. The **IsBlocking** method can be used to determine if the client is already blocked, and if so, take some other action (such as warning the user that they must wait for the operation to complete).

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

Cancel, GetStatus, IsConnected, IsInitialized, IsReadable, IsWritable, Read, Write

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSmtpClient::IsConnected Method

```
BOOL IsConnected();
```

The **IsConnected** method is used to determine if the client is currently connected to a server.

Parameters

None.

Return Value

If the client is connected to a server, the method returns a non-zero value. If the client is not connected, or the client handle is invalid, the method returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

See Also

GetStatus, IsBlocking, IsInitialized, IsReadable, IsWritable

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSmtpClient::IsInitialized Method

```
BOOL IsInitialized();
```

The **IsInitialized** method returns whether or not the class object has been successfully initialized.

Parameters

None.

Return Value

This method returns a non-zero value if the class object has been successfully initialized. A return value of zero indicates that the runtime license key could not be validated or the networking library could not be loaded by the current process.

Remarks

When an instance of the class is created, the class constructor will attempt to initialize the component with the runtime license key that was created when SocketTools was installed. If the constructor is unable to validate the license key or load the networking libraries, this initialization will fail.

If SocketTools was installed with an evaluation license, the application cannot be redistributed to another system. The class object will fail to initialize if the application is executed on another system, or if the evaluation period has expired. To redistribute your application, you must purchase a development license which will include the runtime key that is needed to redistribute your software to other systems. Refer to the Developer's Guide for more information.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

See Also

CSmtpClient, IsBlocking, IsConnected

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSmtpClient::IsReadable Method

```
BOOL IsReadable(
   INT nTimeout,
   LPDWORD lpdwAvail
);
```

The **IsReadable** method is used to determine if data is available to be read from the server.

Parameters

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

lpdwAvail

A pointer to an unsigned integer which will contain the number of bytes available to read. This parameter may be NULL if this information is not required.

Return Value

If the client can read data from the server within the specified timeout period, the method returns a non-zero value. If the client cannot read any data, the method returns zero.

Remarks

On some platforms, this value will not exceed the size of the receive buffer (typically 64K bytes). Because of differences between TCP/IP stack implementations, it is not recommended that your application exclusively depend on this value to determine the exact number of bytes available. Instead, it should be used as a general indicator that there is data available to be read.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

See Also

GetStatus, IsBlocking, IsConnected, IsInitialized, IsWritable, Write

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSmtpClient::IsWritable Method

```
BOOL IsWritable(
   INT nTimeout
);
```

The **IsWritable** method is used to determine if data can be written to the server.

Parameters

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

Return Value

If the client can write data to the server within the specified timeout period, the method returns a non-zero value. If the client cannot write any data, the method returns zero.

Remarks

Although this method can be used to determine if some amount of data can be sent to the remote process it does not indicate the amount of data that can be written without blocking the client. In most cases, it is recommended that large amounts of data be broken into smaller logical blocks, typically some multiple of 512 bytes in length.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

See Also

GetStatus, IsBlocking, IsConnected, IsInitialized, IsReadable, Write

CSmtpClient::Read Method

```
INT Read(
   LPBYTE lpBuffer,
   INT cbBuffer
);

INT Read(
   CString& strBuffer,
   INT cbBuffer
);
```

The **Read** method reads the specified number of bytes from the client socket and copies them into the buffer. The data may be of any type, and is not terminated with a null character.

Parameters

lpBuffer

Pointer to the buffer in which the data will be copied. An alternate form of this method allows a **CString** variable to be passed and data read from the socket will be returned in that string.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

Return Value

If the method succeeds, the return value is the number of bytes actually read. A return value of zero indicates that the server has closed the connection and there is no more data available to be read. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

When **Read** is called and the client is in non-blocking mode, it is possible that the method will fail because there is no available data to read at that time. This should not be considered a fatal error. Instead, the application should simply wait to receive the next asynchronous notification that data is available.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

See Also

EnableEvents, IsBlocking, IsReadable, IsWritable, RegisterEvent, Write

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSmtpClient::RegisterEvent Method

```
INT RegisterEvent(
   UINT nEventId,
   SMTPEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

The **RegisterEvent** method registers an event handler for the specified event.

Parameters

nEventId

An unsigned integer which specifies which event should be registered with the specified callback function. One of the following values may be used:

Value	Description
SMTP_EVENT_CONNECT	The connection to the server has completed.
SMTP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
SMTP_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
SMTP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
SMTP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
SMTP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
SMTP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.
SMTP_EVENT_PROGRESS	The client is in the process of sending or receiving a file on the data channel. This event is called periodically during a transfer so that the client can update any user interface components such as a status control or progress bar.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **SmtpEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **RegisterEvent** method associates a callback function with a specific event. The event handler is an **SmtpEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

This method is typically used to register an event handler that is invoked while a message is being submitted to the server for delivery. The SMTP_EVENT_PROGRESS event will only be generated periodically during the transfer to ensure the application is not flooded with event notifications. It is guaranteed that at least one SMTP_EVENT_PROGRESS notification will occur at the beginning of the transfer, and one at the end of the transfer when it has completed.

The callback function specified by the *lpEventProc* parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

The *dwParam* parameter is commonly used to identify the class instance which is associated with the event that has occurred. Applications will cast the **this** pointer to a DWORD_PTR value when calling this function, and then the event handler will cast it back to a pointer to the class instance. This gives the handler access to the class member variables and methods.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

CSmtpClient::Reset Method

```
INT Reset();
```

The **Reset** method resets the client state and resynchronizes with the server. This method is typically called after an unexpected error has occurred, or an operation has been canceled.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The client cannot be reset while in a blocked state.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

CSmtpClient::SendMessage Method

```
INT SendMessage(
   LPCTSTR lpszFrom,
   LPCTSTR lpszRecipient,
   LPCTSTR lpszFileName
);

INT SendMessage(
   LPCTSTR lpszFrom,
   LPCTSTR lpszRecipient,
   LPBYTE lpMessage,
   DWORD dwMessageSize
);

INT SendMessage(
   LPCTSTR lpszFrom,
   LPCTSTR lpszRecipient,
   HGLOBAL hgblMessage,
   DWORD dwMessageSize
);
```

The **SendMessage** method sends the contents of a file or buffer to the specified recipients.

Parameters

lpszFrom

Pointer to a string which specifies the email address of the sender.

lpszRecipient

Pointer to a string which specifies the recipient of the message. Multiple recipients may be specified by separating each address with a comma.

lpszFileName

Pointer to a string which specifies a file that contains the message to be delivered.

lpMessage

Pointer to a buffer which contains the message to be delivered. This may also be a global memory handle which references the message data.

dwMessageSize

An unsigned integer which specifies the length of the message in bytes.

Return Value

If the method succeeds, the return value is the result code from the server. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **SendMessage** method is used to send the contents of a file, buffer or global memory handle to the specified recipients. The message must be in the standard format as described in RFC 822. The **CMailMessage** class can be used to compose and export a message in the correct format.

This protocol is only concerned with the delivery of a message and not its contents. Header fields in the message are not parsed to determine the recipients. This recipient parameter should be a concatenation of all recipients, including carbon copies and blind carbon copies, with each address separated with a comma.

This method will cause the current thread to block until the complete message has been delivered, a timeout occurs or the operation is canceled. During the transfer, the SMTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **EnableEvents**, or by registering a callback function using the **RegisterEvent** method.

To determine the current status of the transaction while it is in progress, use the **GetTransferStatus** method.

An alternative approach to creating a message without using the **CMailMessage** class is the **SubmitMessage** method. It accepts two structure parameters which define the message contents and the connection information for the mail server. This enables the application to compose the message and submit it for delivery in a single method call.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

CSmtpClient::SetDeliveryOptions Method

```
BOOL SetDeliveryOptions(
   DWORD dwOptions
);
```

The **SetDeliveryOptions** method sets the delivery status notification options for the current session.

Parameters

dwOptions

A bitmask that defines the current delivery options. This value is created by combining one or more of the following constants with a bitwise Or operator:

Value	Description
SMTP_NOTIFY_NEVER	Never return information about the success or failure of the message delivery process.
SMTP_NOTIFY_SUCCESS	Return a message to the sender if the message has been successfully delivered to the recipient's mail server.
SMTP_NOTIFY_FAILURE	Return a message to the sender if the message could not be delivered to the recipient's mail server.
SMTP_NOTIFY_DELAY	Return a message to the sender if delivery of the message was delayed.
SMTP_RETURN_HEADERS	Return only the message headers to the sender.
SMTP_RETURN_MESSAGE	Return the complete message headers and body to the sender.

Return Value

If the method succeeds, the return value is a non-zero value. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **SetDeliveryOptions** method sets the current delivery options for the client session. Note that delivery options are only available on those mail servers which support delivery status notification (DSN) using the extended SMTP protocol. The client must connect specifying SMTP_OPTION_EXTENDED in order to use extended server options.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetDeliveryOptions, GetExtendedOptions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSmtpClient::SetLastError Method

```
VOID SetLastError(
   DWORD dwErrorCode
);
```

The **SetLastError** method sets the last error code for the current thread. This method is typically used to clear the last error by specifying a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or SMTP_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

Applications can retrieve the value saved by this method by using the **GetLastError** method. The use of **GetLastError** is optional; an application can call the method to determine the specific reason for a method failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

See Also

GetErrorString, GetLastError, ShowError

CSmtpClient::SetLocalName Method

```
BOOL SetLocalName(
   LPCTSTR lpszLocalName
);
```

The **SetLocalName** method sets the local domain name used to identify the client to the mail server.

Parameters

lpszLocalName

A null-terminated string which specifies the local domain name to be used by the client when establishing a connection with the mail server. A value of NULL or an empty string clears the domain name.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **SetLocalName** method should only be used to specify a domain name if it is absolutely necessary. In most cases, it is preferable to allow the library to automatically determine the correct domain name to use. Providing an invalid domain name may cause the mail server to reject the connection.

This method may only be called prior to establishing a connection with the mail server using the **Connect** method. After the connection has been made, this method will fail. To change the local domain name used by the client, you must first terminate the current session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CSmtpClient::SetTimeout Method

```
INT SetTimeout(
   UINT nTimeout
);
```

The **SetTimeout** method sets the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the method will fail and return to the caller.

Parameters

nTimeout

The number of seconds to wait for a blocking operation to complete.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The timeout value is only used with blocking client connections.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

CSmtpClient::ShowError Method

```
INT ShowError(
   LPCTSTR lpszAppTitle,
   UINT uType,
   DWORD dwErrorCode
);
```

The **ShowError** method displays a message box which describes the specified error.

Parameters

lpszAppTitle

A null-terminated string which specifies the title of the message box that is displayed. If this argument is NULL or omitted, then the default title of "Error" will be displayed.

uType

An unsigned integer which specifies the type of message box that will be displayed. This is the same value that is used by the **MessageBox** method in the Windows API. If a value of zero is specified, then a message box with a single OK button will be displayed. Refer to that method for a complete list of options.

dwErrorCode

Specifies the error code that will be used when displaying the message box. If this argument is zero, then the last error that occurred in the current thread will be displayed.

Return Value

If the method is successful, the return value will be the return value from the **MessageBox** function. If the method fails, it will return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

CSmtpClient::SubmitMessage Method

```
BOOL SubmitMessage(
   LPSMTPSERVER lpServer,
   LPSMTPMESSAGE lpMessage,
   SMTPEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);

BOOL SubmitMessage(
   LPSMTPSERVER lpServer,
   LPSMTPMESSAGEEX lpMessage,
   SMTPEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

The **SubmitMessage** method composes and submits a message for delivery to the specified mail server.

Parameters

lpServer

A pointer to an **SMTPSERVER** structure that contains information about the mail server that the message will be submitted to for delivery. This parameter cannot be NULL and the structure members must be properly initialized prior to calling this function.

lpMessage

A pointer to an **SMTPMESSAGE** or **SMTPMESSAGEEX** structure that contains information about the message, including the sender, recipients and the body of the message. This parameter cannot be NULL and the structure members must be property initialized prior to calling this function.

lpEventProc

An optional pointer to the procedure-instance address of an application defined callback function. For more information about event handling and the callback function, see the description of the **SmtpEventProc** callback function. If this parameter is NULL or is omitted, event notification is disabled.

dwParam

An optional user-defined integer value that is passed to the callback function. If the *lpEventProc* parameter is NULL, this value should be zero.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **SmtpGetLastError**.

Remarks

The **SubmitMessage** method provides a high-level interface that enables an application to send an email message with a single function call. The **SMTPSERVER** and **SMTPMESSAGE** structures are used to provide the function with information about the mail server that will accept the message and the contents of the message itself. Note that this method does not require you to call the **Connect** method prior to calling this function.

If you need to specify additional custom headers in the message that is submitted for delivery, you should use the **SMTPMESSAGEEX** structure. It is an extended version of the message structure which

will allow you to define custom headers to be included in the message.

This method will cause the calling thread to block until the message has been submitted for delivery, an error occurs or the connection to the mail server times out. If an event handler is specified, then the callback function will be periodically invoked as the message is being sent. For large messages, the SMTP_EVENT_PROGRESS event can be used to monitor the submission process and update the user interface. The **GetTransferStatus** method can be used within the callback function to obtain information about the current status of the submission.

Example

```
CSmtpClient smtpClient;

SMTPSERVER mailServer;
ZeroMemory(&mailServer, sizeof(mailServer));
mailServer.lpszHostName = _T("smtp.gmail.com");
mailServer.nHostPort = SMTP_PORT_SUBMIT;
mailServer.lpszUserName = m_strSender;
mailServer.lpszPassword = m_strPassword;
mailServer.dwOptions = SMTP_OPTION_SECURE;

SMTPMESSAGE mailMessage;
ZeroMemory(&mailMessage, sizeof(mailMessage));
mailMessage.lpszFrom = m_strSender;
mailMessage.lpszTo = m_strRecipients;
mailMessage.lpszSubject = m_strSubject;
mailMessage.lpszText = m_strMessage;

if (smtpClient.SubmitMessage(&mailServer, &mailMessage))
    _tprintf(_T("SubmitMessage was successful\n"));
else
{
    CString strError;
    smtpClient.GetErrorString(strError);
    _tprintf(_T("SubmitMessage failed: %s\n"), strError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CSmtpClient::VerifyAddress Method

```
INT VerifyAddress(
   LPCTSTR lpszAddress,
   LPTSTR lpszBuffer,
   INT nMaxLength
);

INT VerifyAddress(
   LPCTSTR lpszAddress,
   CString& strBuffer
);
```

The **VerifyAddress** method verifies the specified address is valid.

Parameters

lpszAddress

Points to a string which specifies the address that the server should verify.

lpszBuffer

Points to a buffer that the verified address will be copied into. This argument may also be a **CString** object which will contain the verified address when the method returns.

nMaxLength

Maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the method succeeds, the return value is the server result code. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **VerifyAddress** method requests that the server verify the specified email address. Typically this is used to verify that a recipient address is valid, and return a fully qualified email address for that recipient. A server may not support this command, or may restrict its usage. An application should not depend on the ability to verify addresses.

This method cannot be called while a mail message is being composed.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

AddRecipient, ExpandAddress

CSmtpClient::Write Method

```
INT Write(
   LPBYTE lpBuffer,
   INT cbBuffer
);

INT Write(
   LPCTSTR lpszBuffer
   INT cbBuffer
);
```

The **Write** method sends the specified number of bytes to the server.

Parameters

lpBuffer

The pointer to the buffer which contains the data that is to be sent to the server. In an alternate form of the method, the pointer is to a string.

cbBuffer

The number of bytes to send from the specified buffer. This value must be greater than zero, unless a pointer to a string buffer is passed as the parameter. In that case, if the value is -1, all of the characters in the string, up to but not including the terminating null character, will be sent to the server.

Return Value

If the method succeeds, the return value is the number of bytes actually written. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The return value may be less than the number of bytes specified by the ***cbBuffer*** parameter. In this case, the data has been partially written and it is the responsibility of the client application to send the remaining data at some later point. For non-blocking clients, the client must wait for the next asynchronous notification message before it resumes sending data.

If the **Write** method is used to send the message contents to the server, the application must first call the **CreateMessage** method to specify the sender and the length of the message, followed by one or more calls to the **AddRecipient** method to specify each recipient of the message. When all of the message text has been submitted to the server, the application must call the **CloseMessage** method.

The message text is filtered by the **Write** method, and it will automatically normalize end-of-line character sequences to ensure the message meets the protocol requirements. The message itself must be in a standard RFC 822 or multi-part MIME message format, or the server may reject the message. Binary data, such as file attachments, should always be encoded. The **CMailMessage** class can be used to compose and export a message in the correct format, which can then be submitted to the server.

It is recommended that most applications use the **SendMessage** method to submit the message for delivery.

An alternative approach to creating a message without using the **CMailMessage** class is the **SubmitMessage** method. It accepts two structure parameters which define the message contents and the connection information for the mail server. This enables the application to compose the message and submit it for delivery in a single method call.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

SECURITYCREDENTIALS

The **SECURITYCREDENTIALS** structure specifies the information needed by the library to specify additional security credentials, such as a client certificate, when establishing a secure connection.

```
typedef struct _SECURITYCREDENTIALS
{
    DWORD    dwSize;
    DWORD    dwProtocol;
    DWORD    dwOptions;
    DWORD    dwReserved;
    LPCTSTR  lpszHostName;
    LPCTSTR  lpszUserName;
    LPCTSTR  lpszPassword;
    LPCTSTR  lpszCertStore;
    LPCTSTR  lpszCertName;
    LPCTSTR  lpszKeyFile;
} SECURITYCREDENTIALS, *LPSECURITYCREDENTIALS;
```

Members

dwSize

Size of this structure. If the structure is being allocated dynamically, this member must be set to the size of the structure and all other unused structure members must be initialized to a value of zero or NULL.

dwProtocol

A bitmask of supported security protocols. The value of this structure member is constructed by using a bitwise operator with any of the following values:

Value	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_TLS	Either the TLS 1.2 or 1.3 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers which reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing

	a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Value	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

dwReserved

This structure member is reserved for future use and should always be initialized to zero.

lpszHostName

A null-terminated string which specifies the hostname that will be used when validating the server certificate. If this member is NULL, then the server certificate will be validated against the hostname used to establish the connection.

lpszUserName

A null-terminated string which identifies the owner of client certificate. Currently this member is not used by the library and should always be initialized as a NULL pointer.

lpszPassword

A null-terminated string which specifies the password needed to access the certificate. Currently this member is only used if the CREDENTIAL_STORE_FILENAME option has been specified. If there is no password associated with the certificate, then this member should be initialized as a NULL pointer.

lpszCertStore

A null-terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A null-terminated string which specifies the name of the certificate to use. The library will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the library will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the library will return an error indicating that the certificate could not be found. If the SECURITY_PROTOCOL_SSH protocol has been specified, this member should be NULL.

lpszKeyFile

This member is not used and should always be NULL. The private key cannot be specified separately and must be associated with the certificate.

Remarks

An application only needs to create this structure if the server requires the client to provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is

specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The ***dwOptions*** member should be set to CREDENTIAL_STORE_FILENAME and the ***lpszCertStore*** member should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS #12. These certificate files typically have an extension of .pfx or .p12. Note that if a password was specified when the certificate file was created, it must be provided in the ***lpszPassword*** member or the library will be unable to access the certificate.

Note that the ***lpszUserName*** and ***lpszPassword*** members are values which are used to access the certificate store or private key file. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SECURITYINFO

The **SECURITYINFO** structure contains security related information about the connection, including the protocol, cipher suite and certificate.

```
typedef struct _SECURITYINFO
{
   DWORD        dwSize;
   DWORD        dwProtocol;
   DWORD        dwCipher;
   DWORD        dwCipherStrength;
   DWORD        dwHash;
   DWORD        dwHashStrength;
   DWORD        dwKeyExchange;
   DWORD        dwCertStatus;
   SYSTEMTIME   stCertIssued;
   SYSTEMTIME   stCertExpires;
   LPCTSTR      lpszCertIssuer;
   LPCTSTR      lpszCertSubject;
   LPCTSTR      lpszFingerprint;
} SECURITYINFO, *LPSECURITYINFO;
```

Members

dwSize

Specifies the size of the data structure. This member must always be initialized to the size of the structure in bytes prior to passing the address of this structure to the function. If this this member is not initialized, an error will be returned indicating that an invalid parameter has been passed to the function.

dwProtocol

A numeric value which specifies the security protocol selected when establishing the connection.

Value	Description
SECURITY_PROTOCOL_NONE	The connection is not secure. This value indicates a standard connection was established and all other structure members will have a value of zero.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol was selected when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol was selected when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.

SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol was selected when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol was selected when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwCipher

A numeric value which specifies the cipher that was selected when establishing the secure connection.

Value	Description
SECURITY_CIPHER_AES	The Advanced Encryption Standard cipher is a fixed block size cipher which use a key size of 128, 192 or 256 bits.
SECURITY_CIPHER_DES	The Data Encryption Standard block cipher was selected. This is a fixed key length cipher, using 56-bit keys.
SECURITY_CIPHER_DES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively providing a 168-bit length key.
SECURITY_CIPHER_DESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.
SECURITY_CIPHER_RC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40 and 128 bits, in 8-bit increments.
SECURITY_CIPHER_RC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.

dwCipherStrength

A numeric value which specifies the strength (the length of the cipher key in bits) of the cipher that was selected. Typically this value will be 128 or 256. 40-bit and 56-bit key lengths are considered weak encryption, and subject to brute force attacks. 128-bit and 256-bit key lengths are considered to be secure, and are the recommended key length for secure communications.

dwHash

A numeric value which specifies the hash algorithm which was selected.

Value	Description
SECURITY_HASH_MD5	The MD5 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA1	The SHA-1 algorithm was selected. Its use has been deprecated and is no longer considered to be

	cryptographically secure.
SECURITY_HASH_SHA256	The SHA-256 algorithm was selected.
SECURITY_HASH_SHA384	The SHA-384 algorithm was selected.
SECURITY_HASH_SHA512	The SHA-512 algorithm was selected.

dwHashStrength

A numeric value which specifies the strength (the length in bits) of the message digest that was selected.

dwKeyExchange

A numeric value which specifies the key exchange algorithm which was selected.

Value	Description
SECURITY_KEYEX_RSA	The RSA public key algorithm was selected.
SECURITY_KEYEX_KEA	The Key Exchange Algorithm (KEA) was selected. This is an improved version of the Diffie-Hellman public key algorithm.
SECURITY_KEYEX_DH	The Diffie-Hellman key exchange algorithm was selected.
SECURITY_KEYEX_ECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography.

dwCertStatus

A numeric value which specifies the status of the certificate returned by the secure server.

Value	Description
SECURITY_CERTIFICATE_VALID	The certificate is valid.
SECURITY_CERTIFICATE_NOMATCH	The certificate is valid, but the domain name does not match the common name in the certificate.
SECURITY_CERTIFICATE_EXPIRED	The certificate is valid, but has expired.
SECURITY_CERTIFICATE_REVOKED	The certificate has been revoked and is no longer valid.
SECURITY_CERTIFICATE_UNTRUSTED	The certificate or certificate authority is not trusted on the local system.
SECURITY_CERTIFICATE_INVALID	The certificate is invalid. This typically indicates that the internal structure of the certificate has been damaged.

stCertIssued

A structure which contains the date and time that the certificate was issued by the certificate authority. If the issue date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values.

stCertExpires

A structure which contains the date and time that the certificate expires. If the expiration date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values.

lpszCertIssuer

A null-terminated string which contains information about the organization that issued the certificate. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate issuer could not be determined, this member may be NULL.

lpszCertSubject

A null-terminated string which contains information about the organization that the certificate was issued to. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate subject could not be determined, this member may be NULL.

lpszFingerprint

A null-terminated string which contains a sequence of hexadecimal values that uniquely identify the server. This member may be NULL.

Remarks

The size of this structure is typically determined using the **sizeof** operator in C/C++ and most other languages have a similar method for obtaining the size of a data structure or user-defined type. It is important to note the size of this structure will be different on 32-bit and 64-bit platforms due to the difference in the length of the structure members which are pointers.

When evaluating structure members which are string pointers, such as ***lpszCertIssuer*** and ***lpszCertSubject***, you should always check to ensure their values are not NULL (zero) before attempting to dereference them. If those values are undefined, it is not guaranteed they will point to zero-length strings.

There are additional protocols and ciphers defined which are not listed above because they are considered insecure and are no longer supported. It is important to note that most servers will reject attempts to use unsupported protocols such as SSL 3.0 and will either abort the connection or issue an error message and then immediately disconnect.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

SMTPMESSAGE

This structure provides information about the contents of a message and is used by the SubmitMessage method.

```
typedef struct _SMTPMESSAGE
{
    LPCTSTR  lpszFrom;
    LPCTSTR  lpszTo;
    LPCTSTR  lpszCc;
    LPCTSTR  lpszBcc;
    LPCTSTR  lpszSubject;
    LPCTSTR  lpszText;
    LPCTSTR  lpszHTML;
    LPCTSTR  lpszAttach;
    UINT     nCharSet;
    UINT     nEncType;
    DWORD    dwReserved;
} SMTPMESSAGE, *LPSMTPMESSAGE;
```

Members

lpszFrom

A null-terminated string that specifies the email address of the person sending the message. This structure member must point to a valid address and cannot be NULL.

lpszTo

A null-terminated string that specifies the email addresses of one or more recipients. If multiple addresses are provided, they must be separated by commas or semi-colons. This structure member must point to at least one valid address and cannot be NULL.

lpszCc

A null-terminated string that specifies the email addresses of one or more recipients that will receive copies of the message. If multiple addresses are provided, they must be separated by commas or semi-colons. This structure member may be NULL or point to an empty string.

lpszBcc

A null-terminated string that specifies the email addresses of one or more recipients that will receive blind copies of the message. If multiple addresses are provided, they must be separated by commas or semi-colons. This structure member may be NULL or point to an empty string. Unlike the recipients specified by the ***lpszTo*** and ***lpszCc*** members, any addresses specified by this member will not be included in the header of the email message.

lpszSubject

A null-terminated string that specifies the subject of the message. This structure member may be NULL, in which case no subject will be included in the message.

lpszText

A null-terminated string which contains the body of the message as plain text. Each line of text contained in the string should be terminated with a carriage-return and linefeed (CRLF) pair, which is recognized as the end-of-line. If this structure member is NULL or points to an empty string, then the ***lpszHTML*** member must specify the body of the message.

lpszHTML

A null-terminated string which contains the message using HTML formatting. If the ***lpszText*** member is not NULL, then a multipart message will be created with both plain text and HTML text

as the alternative. This allows mail clients to select which message body they wish to display. If the ***lpszText*** member is NULL or points to an empty string, then the message will only contain HTML. Although this is supported, it is not recommended because older mail clients may be unable to display the message correctly.

lpszAttach

A null-terminated string which specifies one or more file attachments for the message. If multiple files are to be attached to the message, each file name must be separated by a semi-colon. It is recommended that you provide the complete path to the file. If this structure member is NULL or points to an empty string, the message will be created without attachments.

nCharSet

An integer value which specifies the character set to use when composing the message. A value of zero specifies that the default USASCII character set should be used. The following values may also be used:

Value	Description
MIME_CHARSET_USASCII	Each character is encoded in one or more bytes, with each byte being 8 bits long, with the first bit cleared. This encoding is most commonly used with plain text using the US-ASCII character set, where each character is represented by a single byte in the range of 20h to 7Eh.
MIME_CHARSET_ISO8859_1	An 8-bit character set for most western European languages such as English, French, Spanish and German. This character set is also commonly referred to as Latin1.
MIME_CHARSET_ISO8859_2	An 8-bit character set for most central and eastern European languages such as Czech, Hungarian, Polish and Romanian. This character set is also commonly referred to as Latin2.
MIME_CHARSET_ISO8859_5	An 8-bit character set for Cyrillic languages such as Russian, Bulgarian and Serbian.
MIME_CHARSET_ISO8859_6	An 8-bit character set for Arabic languages. Note that the application is responsible for displaying text that uses this character set. In particular, any display engine needs to be able to handle the reverse writing direction and analyze the context of the message to correctly combine the glyphs.
MIME_CHARSET_ISO8859_7	An 8-bit character set for the Greek language.
MIME_CHARSET_ISO8859_8	An 8-bit character set for the Hebrew language. Note that similar to Arabic, Hebrew uses a reverse writing direction. An application which displays this character should be capable of processing bi-directional text where a single message may include both right-to-left and left-to-right languages, such as Hebrew and English.
MIME_CHARSET_ISO8859_9	An 8-bit character set for the Turkish language. This character set is also commonly referred to as Latin5.

nEncType

A numeric identifier which specifies the encoding type to use when composing the message. A value of zero specifies that default 7bit encoding should be used. The following values may also be

used:

Value	Description
MIME_ENCODING_7BIT	Each character is encoded in one or more bytes, with each byte being 8 bits long, with the most significant bit cleared. This encoding is most commonly used with plain text using the US-ASCII character set, where each character is represented by a single byte in the range of 20h to 7Eh.
MIME_ENCODING_8BIT	Each character is encoded in one or more bytes, with each byte being 8 bits long and all bits are used. 8-bit encoding is typically used with multibyte character sets and is the default encoding used with Unicode text.
MIME_ENCODING_QUOTED	Quoted-printable encoding is designed for textual messages where most of the characters are represented by the ASCII character set and is generally human-readable. Non-printable characters or 8-bit characters with the high bit set are encoded as hexadecimal values and represented as 7-bit text. Quoted-printable encoding is typically used for messages which use character sets such as ISO-8859-1, as well as those which use HTML.

dwReserved

An unsigned integer value reserved for future use. This structure member should always have a value of zero.

Remarks

This structure is used to define the contents of a message that will be submitted for delivery using the **SmtpSubmitMessage** function. It is required that you specify a sender, at least one recipient and a message body. All other structure members may be NULL or have a value of zero to indicate that either the value is not required, or that a default should be used. It is recommended that you initialize all of the structure members to a value of zero using the **ZeroMemory** function prior to populating the structure.

email addresses may be specified as simple addresses, or as commented addresses that include the sender's name or other information. For example, any one of these address formats are acceptable:

```
user@domain.tld
User Name <user@domain.tld>
user@domain.tld (User Name)
```

To specify multiple addresses, you should separate each address by a comma or semi-colon. Note that the *lpszFrom* member cannot specify multiple addresses, however it is permitted with the *lpszTo*, *lpszCc* and *lpszBcc* structure members. Each message must have at least one valid recipient, or the message cannot be submitted for delivery.

To send a message that contains HTML, it is recommended that you provide both a plain text version of the message body and an HTML formatted version. While it is permitted to send a message that only contains HTML, some older mail clients may not be capable of displaying the message correctly. In some cases, anti-spam software will increase the spam score of messages that do not contain a plain text message body. This can result in your message being rejected or quarantined by the mail server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

SMTPMESSAGEEX

This structure provides information about the contents of a message and is used by the SubmitMessage method.

```
typedef struct _SMTPMESSAGEEX
{
    DWORD    dwSize
    LPCTSTR  lpszFrom;
    LPCTSTR  lpszTo;
    LPCTSTR  lpszCc;
    LPCTSTR  lpszBcc;
    LPCTSTR  lpszDate;
    LPCTSTR  lpszSubject;
    LPCTSTR  lpszHeaders;
    LPCTSTR  lpszText;
    LPCTSTR  lpszHTML;
    LPCTSTR  lpszAttach;
    UINT     nCharSet;
    UINT     nEncType;
    DWORD    dwReserved;
} SMTPMESSAGEEX, *LPSMTPMESSAGEEX;
```

Members

dwSize

An integer value that specifies the size of the **SMTPMESSAGEEX** data structure. This must always be explicitly defined, and if the value is incorrect, an error will be returned. This structure member is used to ensure that the correct version of the structure is being passed to the method.

lpszFrom

A null-terminated string that specifies the email address of the person sending the message. This structure member must point to a valid address and cannot be NULL.

lpszTo

A null-terminated string that specifies the email addresses of one or more recipients. If multiple addresses are provided, they must be separated by commas or semi-colons. This structure member must point to at least one valid address and cannot be NULL.

lpszCc

A null-terminated string that specifies the email addresses of one or more recipients that will receive copies of the message. If multiple addresses are provided, they must be separated by commas or semi-colons. This structure member may be NULL or point to an empty string.

lpszBcc

A null-terminated string that specifies the email addresses of one or more recipients that will receive blind copies of the message. If multiple addresses are provided, they must be separated by commas or semi-colons. This structure member may be NULL or point to an empty string. Unlike the recipients specified by the *lpszTo* and *lpszCc* members, any addresses specified by this member will not be included in the header of the email message.

lpszDate

A null-terminated string that specifies the date and time for the message. This structure member may be NULL or point to an empty string. If the date is not specified, then the current date and time will be used by default. If a date is specified, it should be in the standard format as defined by RFC822.

lpszSubject

A null-terminated string that specifies the subject of the message. This structure member may be NULL, in which case no subject will be included in the message.

lpszHeaders

A null-terminated string that specifies additional headers that should be included in the message. Header names should be separated from values by a colon, and multiple headers may be defined by separating them with a newline character. This structure member may be NULL, in which case no additional headers will be included in the message.

lpszText

A null-terminated string which contains the body of the message as plain text. Each line of text contained in the string should be terminated with a carriage-return and linefeed (CRLF) pair, which is recognized as the end-of-line. If this structure member is NULL or points to an empty string, then the ***lpszHTML*** member must specify the body of the message.

lpszHTML

A null-terminated string which contains the message using HTML formatting. If the ***lpszText*** member is not NULL, then a multipart message will be created with both plain text and HTML text as the alternative. This allows mail clients to select which message body they wish to display. If the ***lpszText*** member is NULL or points to an empty string, then the message will only contain HTML. Although this is supported, it is not recommended because older mail clients may be unable to display the message correctly.

lpszAttach

A null-terminated string which specifies one or more file attachments for the message. If multiple files are to be attached to the message, each file name must be separated by a semi-colon. It is recommended that you provide the complete path to the file. If this structure member is NULL or points to an empty string, the message will be created without attachments.

nCharSet

An integer value which specifies the character set to use when composing the message. A value of zero specifies that the default USASCII character set should be used. The following values may also be used:

Value	Description
MIME_CHARSET_USASCII	Each character is encoded in one or more bytes, with each byte being 8 bits long, with the first bit cleared. This encoding is most commonly used with plain text using the US-ASCII character set, where each character is represented by a single byte in the range of 20h to 7Eh.
MIME_CHARSET_ISO8859_1	An 8-bit character set for most western European languages such as English, French, Spanish and German. This character set is also commonly referred to as Latin1.
MIME_CHARSET_ISO8859_2	An 8-bit character set for most central and eastern European languages such as Czech, Hungarian, Polish and Romanian. This character set is also commonly referred to as Latin2.
MIME_CHARSET_ISO8859_5	An 8-bit character set for Cyrillic languages such as Russian, Bulgarian and Serbian.
MIME_CHARSET_ISO8859_6	An 8-bit character set for Arabic languages. Note that the

	application is responsible for displaying text that uses this character set. In particular, any display engine needs to be able to handle the reverse writing direction and analyze the context of the message to correctly combine the glyphs.
MIME_CHARSET_ISO8859_7	An 8-bit character set for the Greek language.
MIME_CHARSET_ISO8859_8	An 8-bit character set for the Hebrew language. Note that similar to Arabic, Hebrew uses a reverse writing direction. An application which displays this character should be capable of processing bi-directional text where a single message may include both right-to-left and left-to-right languages, such as Hebrew and English.
MIME_CHARSET_ISO8859_9	An 8-bit character set for the Turkish language. This character set is also commonly referred to as Latin5.

nEncType

A numeric identifier which specifies the encoding type to use when composing the message. A value of zero specifies that default 7bit encoding should be used. The following values may also be used:

Value	Description
MIME_ENCODING_7BIT	Each character is encoded in one or more bytes, with each byte being 8 bits long, with the most significant bit cleared. This encoding is most commonly used with plain text using the US-ASCII character set, where each character is represented by a single byte in the range of 20h to 7Eh.
MIME_ENCODING_8BIT	Each character is encoded in one or more bytes, with each byte being 8 bits long and all bits are used. 8-bit encoding is typically used with multibyte character sets and is the default encoding used with Unicode text.
MIME_ENCODING_QUOTED	Quoted-printable encoding is designed for textual messages where most of the characters are represented by the ASCII character set and is generally human-readable. Non-printable characters or 8-bit characters with the high bit set are encoded as hexadecimal values and represented as 7-bit text. Quoted-printable encoding is typically used for messages which use character sets such as ISO-8859-1, as well as those which use HTML.

dwReserved

An unsigned integer value reserved for future use. This structure member should always have a value of zero.

Remarks

This structure is used to define the contents of a message that will be submitted for delivery using the **SubmitMessage** method. It is required that you specify a sender, at least one recipient and a message body. Other structure members may be NULL or have a value of zero to indicate that either the value is not required, or that a default should be used. It is recommended that you initialize all of the structure members to a value of zero using the **ZeroMemory** function prior to populating the

structure.

Note that you must explicitly define the size of the structure by setting the value of the **dwSize** member variable. This ensures that the correct version of the structure is being passed to the method.

Email addresses may be specified as simple addresses, or as commented addresses that include the sender's name or other information. For example, any one of these address formats are acceptable:

```
user@domain.tld
User Name <user@domain.tld>
user@domain.tld (User Name)
```

To specify multiple addresses, you should separate each address by a comma or semi-colon. Note that the *lpszFrom* member cannot specify multiple addresses, however it is permitted with the *lpszTo*, *lpszCc* and *lpszBcc* structure members. Each message must have at least one valid recipient, or the message cannot be submitted for delivery.

If you specify a message date by assigning a value to the *lpszDate* member, and it does not include any timezone information, Coordinated Universal Time (UTC) will be used by default. This is an important consideration if you provide input from a user, because in most cases they will not include the timezone and will assume the date and time they enter is for their current timezone.

If you wish to include additional headers in the message, you can specify them in a string. Each header consists of a name and value, separated by a colon (":") character. If you wish to define multiple headers, then you can separate them with a newline (e.g.: a linefeed character or combination of a carriage-return and linefeed). Extraneous leading and trailing whitespace are trimmed from header names and values. Invalid names or values will be ignored and will not generate an error.

To send a message that contains HTML, it is recommended that you provide both a plain text version of the message body and an HTML formatted version. While it is permitted to send a message that only contains HTML, some older mail clients may not be capable of displaying the message correctly. In some cases, anti-spam software will increase the spam score of messages that do not contain a plain text message body. This can result in your message being rejected or quarantined by the mail server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

SMTPSERVER

This structure provides connection information for a mail server and is used by the SubmitMessage method.

```
typedef struct _SMTPSERVER
{
    LPCTSTR  lpszHostName;
    LPCTSTR  lpszUserName;
    LPCTSTR  lpszPassword;
    UINT     nHostPort;
    UINT     nTimeout;
    DWORD    dwOptions;
    DWORD    dwReserved;
} SMTPSERVER, *LPSMTPSERVER;
```

Members

lpszHostName

A null-terminated string that specifies the host name or IP address of the mail server. This structure member cannot be NULL.

lpszUserName

A null-terminated string that specifies the username that will be used to authenticate the client session. If the mail server does not require authentication, this structure member can be NULL or point to an empty string.

lpszPassword

A null-terminated string that specifies the password that will be used to authenticate the client session. If the mail server does not require authentication, this structure member can be NULL or point to an empty string.

nHostPort

An integer value that specifies the port number used to establish the connection. A value of zero specifies that the default port number should be used. For standard connections, the default port number is 25. An alternative port is 587, which is commonly used by authenticated clients to submit messages for delivery. For implicit TLS connections, the default port number is 465.

nTimeout

An integer value that specifies the number of seconds that the client will wait for a response from the server before failing the operation. A value of zero specifies the default timeout period of 20 seconds.

dwOptions

An unsigned integer that specifies one or more options. The value of this structure member is constructed by using a bitwise operator with any of the following values:

Value	Description
SMTP_OPTION_NONE	No additional options are specified when establishing a connection with the server. A standard, non-secure connection will be used.
SMTP_OPTION_EXTENDED	Extended SMTP commands should be used if possible. This option enables features such as authentication and delivery status notification. If this option is not

	specified, the library will not attempt to use any extended features. This option is automatically enabled if a username and password are specified, or if the connection is established on port 587, because submitting messages for delivery using this port typically requires client authentication.
SMTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
SMTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
SMTP_OPTION_SECURE	This option specifies that a secure connection should be established with the server and requires that the server support the TLS protocol. The client will initiate the secure session using the STARTTLS command.
SMTP_OPTION_SECURE_IMPLICIT	This option specifies the client should attempt to establish a secure connection with the server. The server must support secure connections using the TLS protocol, and the secure session must be negotiated immediately after the connection has been established.

dwReserved

An unsigned integer value reserved for future use. This structure member should always have a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

SMTPTRANSFERSTATUS

This structure is used by the GetTransferStatus method to return information about a message being submitted for delivery.

```
typedef struct _SMTPTRANSFERSTATUS
{
   DWORD   dwBytesTotal;
   DWORD   dwBytesCopied;
   DWORD   dwBytesPerSecond;
   DWORD   dwTimeElapsed;
   DWORD   dwTimeEstimated;
} SMTPTRANSFERSTATUS, *LPSMTPTRANSFERSTATUS;
```

Members

dwBytesTotal

The total number of bytes that will be transferred. If the size of the message cannot be determined, this value will be zero.

dwBytesCopied

The total number of bytes that have been copied.

dwBytesPerSecond

The average number of bytes that have been copied per second.

dwTimeElapsed

The number of seconds that have elapsed since the file transfer started.

dwTimeEstimated

The estimated number of seconds until the transfer is completed. This is based on the average number of bytes transferred per second.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

SYSTEMTIME

The **SYSTEMTIME** structure represents a date and time using individual members for the month, day, year, weekday, hour, minute, second, and millisecond.

```
typedef struct _SYSTEMTIME
{
    WORD wYear;
    WORD wMonth;
    WORD wDayOfWeek;
    WORD wDay;
    WORD wHour;
    WORD wMinute;
    WORD wSecond;
    WORD wMilliseconds;
} SYSTEMTIME, *LPSYSTEMTIME;
```

Members

wYear

Specifies the current year. The year value must be greater than 1601.

wMonth

Specifies the current month. January is 1, February is 2 and so on.

wDayOfWeek

Specifies the current day of the week. Sunday is 0, Monday is 1 and so on.

wDay

Specifies the current day of the month

wHour

Specifies the current hour.

wMinute

Specifies the current minute

wSecond

Specifies the current second.

wMilliseconds

Specifies the current millisecond.

SocketWrench Class Library

A general purpose TCP/IP networking library for developing client and server applications.

Reference

- Class Methods
- Data Structures
- Error Codes

Library Information

Class Name	CSocketWrench
File Name	CSWSKV12.DLL
Version	12.0.3024.1286
LibID	99EEE601-E935-4266-B046-771A823DB47D
Import Library	CSWSKV12.LIB
Dependencies	None
Standards	RFC 768, RFC 791, RFC 793

Overview

At the core of all of the SocketTools networking libraries is the Windows Sockets API. This provides a low level interface for sending and receiving data over the Internet or a local intranet using the Transmission Control Protocol (TCP) and/or User Datagram Protocol (UDP). The SocketWrench class library provides a simpler interface to the Windows Sockets API, without sacrificing features or functionality. Using SocketWrench, you can easily create client and server applications while avoiding many of the mundane tasks and common problems that developers face when building Internet applications.

This class library supports secure connections using the TLS 1.2 and TLS 1.3 protocols and can also be used to create secure, customized server applications. Both implicit and explicit TLS connections are supported, enabling the class to work with a wide variety of client and server applications without requiring third-party encryption libraries.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). You should install all updates for your development tools and have the current Windows SDK installed. The minimum supported version of Visual Studio is Visual Studio 2010 with Service Pack 1 (SP1) installed. The SocketTools header files are designed to be compatible with all modern C/C++ compilers and we also provide function definitions for several additional languages such as Object Pascal and Visual Basic.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are deploying applications to Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. If you are deploying applications to Windows 8, you must have the 8.1 update installed. If you are targeting the Windows on ARM platform, the minimum required version is Windows 10 build 1709.

SocketTools includes support for both 64-bit and 32-bit Windows platforms. All current versions of Windows are 64-bit, and we include 32-bit x86 libraries to maintain compatibility with legacy development tools. SocketTools also provides native ARM64 libraries for systems running Windows on ARM. Note that 32-bit applications on ARM use x86 emulation, and Microsoft no longer supports native 32-bit ARM (ARM32) applications. Embarcadero's C++Builder and Delphi compilers (as of version 12.3) do not support building native ARM64 applications for Windows. For developing applications targeting the Windows on ARM platform, we recommend using Visual Studio 2019 or later.

The import libraries included with SocketTools are provided in several different formats. The most commonly used format is COFF, which is available for x64, x86 and native ARM64 platforms. For compatibility with older Borland (Embarcadero) compilers, we also provide OMF libraries for x86 platforms and ELF libraries for x64 platforms. If you are using Visual Studio, you will want to use the standard COFF import libraries. Note that some languages may not require import libraries and will link to the exported functions in the DLL based on the function declaration itself.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

SocketWrench Class Methods

Class	Description
CSocketWrench	Constructor which initializes the current instance of the class
~CSocketWrench	Destructor which releases resources allocated by the class
Method	Description
Abort	Abort the connection and immediately close the socket
Accept	Accept a connection request from a remote host
AttachHandle	Attach the specified client handle to this instance of the class
AttachThread	Attach the specified socket to another thread
Cancel	Cancel a blocking operation
CompareAddress	Compare two IP addresses to determine if they are identical
Connect	Connect to the specified server
ConnectUrl	Connect to the specified server using a URL
CreateSecurityCredentials	Create a new security credentials structure
DeleteSecurityCredentials	Delete a previously created security credentials structure
DetachHandle	Detach the handle for the current instance of this class
DisableEvents	Disable asynchronous event notification
DisableSecurity	Disable secure communication with the remote host
DisableTrace	Disable logging of network function calls
Disconnect	Disconnect from the current server
EnableEvents	Enable asynchronous event notification
EnableSecurity	Enable secure communication with the remote host
EnableTrace	Enable logging of network function calls to a file
EnumNetworkAddresses	Return the list of network addresses that are configured for the local host
Flush	Flush the send and receive buffers
FormatAddress	Convert an IP address in binary format into a printable string
FreezeEvents	Suspend or resume event handling by the application
GetAdapterAddress	Return the IP or MAC assigned to the specified network adapter
GetAddress	Convert an IP address string to a binary format
GetAddressFamily	Return the address family for the specified IP address
GetDefaultHostFile	Return the fully qualified path name of the host file on the local system
GetErrorString	Return a description for the specified error code
GetExternalAddress	Return the external IP address assigned to the local system

GetFirstAlias	Return the first alias for the specified host name
GetHandle	Return the client handle used by this instance of the class
GetHostAddress	Return the IP address assigned to the specified hostname
GetHostFile	Return the name of the host file
GetHostName	Return the hostname assigned to the specified IP address
GetLastError	Return the last error code
GetLocalAddress	Return the local IP address and port number for a socket
GetLocalName	Return the hostname assigned to the local system
GetMemoryUsage	Return the amount of memory allocated for the network connection
GetNextAlias	Return the next alias for the specified host name
GetOption	Return the current socket options
GetPeerAddress	Return the IP address of the peer that the socket is connected to
GetPeerPort	Returns the remote port number used by the client to establish the connection
GetPhysicalAddress	Return the media access control (MAC) address for the primary network adapter
GetSecurityInformation	Return information about the security characteristics of a connection
GetServiceName	Return the service name associated with a specified port number
GetServicePort	Return the port number associated with a service name
GetStatus	Report what sort of socket operation is in progress
GetStreamInfo	Return information about the current stream read or write operation
GetTimeout	Return the timeout interval for blocking operations, in seconds
GetUrlHostName	Return the host name and port number specified in a URL
GetVpnAdapter	Return the name of the active Virtual Private Network adapter
HostNameToUnicode	Converts the canonical form of a host name to its Unicode version
InetEventProc	Callback method that processes events generated on the socket
IsAddressNull	Determine if the specified IP address is a null address
IsAddressRoutable	Determine if the specified IP address is routable over the Internet
IsBlocking	Determine if the socket is performing a blocking operation
IsClosed	Determine if the remote host has closed its socket
IsConnected	Determine if the socket is connected to a remote host
IsInitialized	Determine if the class has been successfully initialized
IsListening	Determine if the socket is listening for a connection
IsProtocolAvailable	Determine if the specified protocol and address family are supported
IsReadable	Determine if data can read from the socket without blocking
IsUrgent	Determine if there is any out-of-band data available to be read
IsWritable	Determine if data can be written to to the socket without blocking

Listen	Listen for client connections on the specified socket
MatchHostName	Match a host name against of list of addresses including wildcards
NormalizeHostName	Return the canonical form of a host name
Peek	Read data from the socket without removing it from the socket buffer
Read	Read data from the socket
ReadLine	Read a line of data from the socket, storing it in a string buffer
ReadStream	Read a stream of data from the socket
RegisterEvent	Register an event callback function
Reject	Reject a pending client connection
SetHostFile	Specify the name of an alternate host table
SetLastError	Set the last error code
SetOption	Set one or more options for the current socket
SetTimeout	Set the interval used when waiting for a blocking operation to complete
ShowError	Display a message box with a description of the specified error
Shutdown	Disable reception or transmission of data
StoreStream	Read a stream of data from the socket and store it in a file
ValidateCertificate	Validate the specified security certificate is installed on the local system
ValidateHostName	Validate the specified host name and return the resolved IP address
Write	Write data to the socket
WriteLine	Write a line of data to the socket, terminated with a carriage-return and linefeed
WriteStream	Write a stream of data to the socket

CSocketWrench::CSocketWrench Method

```
CSocketWrench();
```

The **CSocketWrench** constructor initializes the class library and validates the license key at runtime.

Remarks

If the constructor fails to validate the runtime license, subsequent methods in this class will fail. If the product is installed with an evaluation license, then the application will only function on the development system and cannot be redistributed.

The constructor calls the **InetInitialize** function to initialize the library, which dynamically loads other system libraries and allocates thread local storage. If you are using this class within another DLL, it is important that you do not create or destroy an instance of the class from within the **DllMain** function because it can result in deadlocks or access violation errors. You should not declare static or global instances of this class within another DLL if it is linked with the C runtime library (CRT) because it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

~CSocketWrench, IsInitialized

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSocketWrench::~CSocketWrench

```
~CSocketWrench();
```

The **CSocketWrench** destructor releases resources allocated by the current instance of the **CSocketWrench** object. It also uninitializes the library if there are no other concurrent uses of the class.

Remarks

When a **CSocketWrench** object goes out of scope, the destructor is automatically called to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all handles that were created for the connection are destroyed.

The destructor is not called explicitly by the application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

CSocketWrench

CSocketWrench::Abort Method

```
BOOL Abort();
```

Immediately close the socket without waiting for any remaining data to be written out.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **Abort** method should only be used when the connection must be closed immediately before the application terminates. This method should only be used to abort client connections and should not be used with passive (listening) sockets. Server applications that need to abort an incoming client connection should use the **Reject** method.

In most cases, the application should call the **Disconnect** method to gracefully close the connection to the remote host. Aborting the connection will discard any buffered data and may cause errors or result in unpredictable behavior.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

CSocketWrench::Accept Method

```
BOOL Accept(
   SOCKET hSocket,
   UINT nTimeout,
   DWORD dwOptions
);

BOOL Accept(
   CSocketWrench& swServer,
   UINT nTimeout,
   DWORD dwOptions
);
```

The **Accept** method is used to accept a pending client connection.

This method has been deprecated and is included for backwards compatibility. Use the **CInternetServer** class to create a server application.

Parameters

hSocket

Handle to the listening socket. This argument may also reference a **CSocketWrench** object which is listening for connections. In either case, the server socket must have been created by calling the **Listen** method.

nTimeout

The number of seconds that the server will wait for a client connection before failing the operation. This value is used only for blocking connections.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
INET_OPTION_KEEPALIVE	This option specifies that packets are to be sent to the remote system when no data is being exchanged to keep the connection active. This is only valid for stream sockets.
INET_OPTION_REUSEADDRESS	This option specifies the local address can be reused. This option is commonly used by server applications.
INET_OPTION_NODELAY	This option disables the Nagle algorithm, which buffers unacknowledged data and insures that a full-size packet can be sent to the remote host.
INET_OPTION_INLINE	This option controls how urgent (out-of-band) data is handled when reading data from the socket. If set, urgent data is placed in the data stream along with non-urgent data.
INET_OPTION_NOINHERIT	This option prevents the socket handle from being inherited by child processes created by the application. Using this option can mitigate situations in which a child process does not close the handle,

	leaving it open after the parent process has stopped the server.
INET_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the TLS protocol.
INET_OPTION_SECURE	This option determines if a secure connection is established with the remote host.
INET_OPTION_SECURE_FALLBACK	This option specifies the server should permit the use of less secure cipher suites for compatibility with legacy clients. If this option is specified, the server will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
INET_OPTION_FREETHREAD	This option specifies that this instance of the class may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the class instance is synchronized across multiple threads.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

When a connection is accepted by the server, the original listening socket continues to listen for more connections. If no event notification window is specified, then **Accept** will block until a client attempts to connect to the server or the timeout period expires.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the class instance is initially attached to the thread that created it. From that point on, until the handle is released, only the owner may call methods using that instance of the class. The ownership of the class instance may be transferred from one thread to another using the **AttachThread** method.

Specifying the INET_OPTION_FREETHREAD option enables any thread to call any method in that instance of the class, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the class instance is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same instance.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

CSocketWrench::AttachHandle Method

```
VOID AttachHandle(
   SOCKET hSocket
);

VOID AttachHandle(
   SOCKET hSocket,
   DWORD dwProcessId
);
```

The **AttachHandle** method attaches the specified socket handle to the current instance of the class.

Parameters

hSocket

The socket handle that will be attached to the current instance of the class object.

dwProcessId

The process ID for the process that currently owns the socket handle. This value may be zero to specify the current process.

Return Value

None.

Remarks

This method is used to attach a socket handle created outside of the class using the SocketWrench API. Once the socket handle is attached to the class, the other class member functions may be used with that socket. If the socket was created by a third-party library or the Windows Sockets API, then the handle will be automatically inherited by the library.

If a socket handle has already been created for the class, that handle will be released when the new handle is attached to the class object. If you want to prevent the previous socket connection from being terminated, you must call the **DetachHandle** method. Failure to release the detached handle may result in a resource leak in your application.

If the *dwProcessId* parameter specifies another process, the socket will be duplicated into the current process, attached to the current thread and the original socket handle will be closed in the other process. This enables an application to effectively take control of a connection created by another process. The original socket handle must be inheritable by the by the current process and must be an actual Windows socket handle, not a pseudo-handle. This functionality is only supported on Windows NT 4.0 and later versions of the operating system with the Microsoft TCP/IP stack. Note that Layered Service Providers (LSPs) may interfere with the ability to inherit handles across processes.

If the socket was created by another process, it is initialized by the library in a blocking state, even if was originally using asynchronous socket events. If the application requires that the socket use events, it must explicitly call **EnableEvents**. A program should never try to attach to a secure connection created by another process because the attached socket will not have the security context required to encrypt and decrypt the data exchanged with the remote host.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h

Import Library: cswskv12.lib

See Also

AttachThread, DetachHandle, GetHandle

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSocketWrench::AttachThread Method

```
DWORD AttachThread(
   DWORD dwThreadId
);
```

The **AttachThread** method attaches the specified client handle to another thread.

Parameters

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the method succeeds, the return value is the thread ID of the previous owner. If the method fails, the return value is INET_ERROR. To get extended error information, call **GetLastError**.

Remarks

When a client handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in a client application to create the client handle, and then pass that handle to another worker thread. The **AttachThread** method can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the method, the original owner of the handle can be restored before the worker thread terminates.

This method should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **AttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **Cancel** method and then release the handle after the blocking method exits and control is returned to the current thread.

Note that the ***dwThreadId*** parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the client handle used by the class until the destructor is called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

AttachHandle, Cancel, Connect, DetachHandle, Disconnect, GetHandle

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSocketWrench::Cancel Method

```
BOOL Cancel(
   SOCKET hSocket
);

BOOL Cancel();
```

The **Cancel** method cancels any outstanding blocking socket operation, causing the blocking method to fail. The application may then retry the operation or terminate the connection.

Parameters

hSocket

An optional parameter that specifies the handle to the socket. If this parameter is omitted, the socket handle for the current class instance will be used.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

When the **Cancel** method is called, the blocking method will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

This method is typically called from within an event handler to signal that the current blocking operation should stop. It may also be used to cancel a blocking operation that is occurring on another thread.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

CSocketWrench::CompareAddress Method

```
BOOL CompareAddress(
   LPINTERNET_ADDRESS lpAddress1,
   LPINTERNET_ADDRESS lpAddress2
);

BOOL CompareAddress(
   LPCTSTR lpszAddress1,
   LPCTSTR lpszAddress2
);
```

Compare two IP addresses to determine if they are identical.

Parameters

lpAddress1

A pointer to an INTERNET_ADDRESS structure that contains the first IP address to be compared. An alternate version of this method accepts a string that specifies the IP address to be compared.

lpAddress2

A pointer to an INTERNET_ADDRESS structure that contains the second IP address to be compared. An alternate version of this method accepts a string that specifies the IP address to be compared.

Return Value

If the method succeeds and the two addresses are identical, the return value is non-zero. If the method fails or the two addresses are not identical, the return value is zero. If either parameter is NULL, or the address family for the two addresses are not the same, the last error code will be updated. If the addresses are valid and in the same address family, but are not identical, the last error code will be set to NO_ERROR.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

GetHostAddress, GetLocalAddress, GetPeerAddress, INTERNET_ADDRESS

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSocketWrench::Connect Method

```
BOOL Connect(
   LPCTSTR lpszRemoteHost,
   UINT nRemotePort
);

BOOL Connect(
   LPCTSTR lpszRemoteHost,
   UINT nRemotePort,
   UINT nProtocol,
   UINT nTimeout,
   DWORD dwOptions,
   LPCTSTR lpszLocalAddress,
   UINT nLocalPort
);
```

The **Connect** method is used to establish a connection with a server.

Parameters

lpszHostName

A null-terminated string which specifies the host name or IP address of the system you want to connect with. This parameter cannot be a URL and must only specify the name of the remote host. If this parameter is NULL or an empty string, the method will fail with an error indicating the host name is invalid.

nRemotePort

The port number used to establish the connection. Valid port numbers range in value from 1 through 65535 and a value outside if this range will cause the function to fail. Port numbers in the range of 49152 and 65535 are referred to as dynamic ports and are generally reserved for private use by client applications. You cannot specify a port number of zero when establishing an outbound connection.

nProtocol

The protocol to be used when establishing the connection. This may be one of the following values:

Value	Description
INET_PROTOCOL_TCP	Specifies the Transmission Control Protocol. This protocol provides a reliable, bi-directional byte stream. This is the default protocol.
INET_PROTOCOL_UDP	Specifies the User Datagram Protocol. This protocol is message oriented, sending data in discrete packets. Note that UDP is unreliable in that there is no way for the sender to know that the receiver has actually received the datagram.

nTimeout

The number of seconds to wait for a response before failing the current operation.

dwOptions

An unsigned integer used to specify one or more socket options. This parameter is constructed by using the bitwise Or operator with any of the following values:

Value	Description

INET_OPTION_BROADCAST	This option specifies that broadcasting should be enabled for datagrams. This option is invalid for stream sockets.
INET_OPTION_DONTROUTE	This option specifies default routing should not be used. This option should not be specified unless absolutely necessary.
INET_OPTION_KEEPALIVE	This option specifies that packets are to be sent to the remote system when no data is being exchanged to keep the connection active. This is only valid for stream sockets.
INET_OPTION_NODELAY	This option disables the Nagle algorithm. By default, small amounts of data written to the socket are buffered, increasing efficiency and reducing network congestion. However, this buffering can negatively impact the responsiveness of certain applications. This option disables this buffering and immediately sends data packets as they are written to the socket.
INET_OPTION_NOINHERIT	This option prevents the socket handle from being inherited by child processes created by the application. Using this option can mitigate situations in which a child process does not close the handle, leaving it open after the parent process has disconnected from the server.
INET_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the TLS protocol.
INET_OPTION_SECURE	This option specifies that a secure connection should be established with the remote host. The specific version of TLS and other security related options are provided in the ***lpCredentials*** parameter. If the ***lpCredentials*** parameter is NULL, the connection will default to using TLS 1.2 or later and the strongest cipher suites available.
INET_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
INET_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a

	connection using IPv6 regardless if this option has been specified.
INET_OPTION_FREETHREAD	This option specifies that this instance of the class may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the class instance is synchronized across multiple threads.

lpszLocalAddress

A null-terminated string that specifies the local IP address that the socket should be bound to. If this parameter is NULL, then an appropriate address will automatically be used. A specific address should only be used if it is required by the application.

nLocalPort

The local port number that the socket should be bound to. If this parameter is set to zero, then an appropriate port number will automatically be used. A specific port number should only be used if it is required by the application.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The *lpszHostName* parameter must specify a valid host name or IP address. Host names are resolved into an IP address by first checking the local hosts file and if the name is not found, a name server query will be performed to determine the IP address. If the Unicode version of this function is called and the host name includes non-ASCII characters, the host name will be automatically converted to an ASCII compatible format. Refer to the **NormalizeHostName** method for more information. To establish a connection using a URL rather than a host name, use the **ConnectUrl** method.

This method will block the current thread until a connection has been established or the timeout period has elapsed. To prevent it from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling the **Connect** method in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each connection.

If you use the INET_OPTION_SECURE option to enable a secure connection, the connection will always use implicit TLS. This means a secure session will be initiated immediately after the socket connection has been established with the server. A common example of a service which uses implicit TLS is the HTTPS protocol. Another type of secure connection is one that uses explicit TLS. This is when the client establishes a normal (non-secure) connection with the server and then explicitly switches to using a secure connection, typically by sending a command. If the server you are connecting to requires explicit TLS, you should not specify the INET_OPTION_SECURE option. Instead, connect without this option and then call the **EnableSecurity** method when you are ready to initiate the TLS handshake.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the class instance is initially attached to the thread that created it. From that point on, until the handle is released, only the owner may call methods using that instance of the class. The ownership of the class instance may be transferred from one thread to another using the **AttachThread** method.

Specifying the INET_OPTION_FREETHREAD option enables any thread to call any method in that instance of the class, regardless of which thread created it. It is important to note that this option

disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the class instance is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same instance.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

ConnectUrl Method

```
BOOL ConnectUrl(
   LPCTSTR lpszUrl,
   UINT nTimeout,
   DWORD dwOptions
);
```

The **ConnectUrl** method is used to establish a TCP connection with a server using the information provided in a URL.

Parameters

lpszUrl

A null-terminated string which specifies a URL used when establishing the connection. This parameter cannot be NULL or point to an empty string. If a non-standard URI scheme is used, the port number must be explicitly specified or the method will fail. See the remarks below for more information on the format supported by this method.

nTimeout

The number of seconds to wait for the connection to complete before failing the current operation. This parameter is optional and if omitted or the value is zero, a default timeout period will be used.

dwOptions

An unsigned integer used to specify one or more socket options. This parameter is optional and if omitted, no additional options will be specified. This parameter value is constructed by using the bitwise Or operator with any of the following values:

Value	Description
INET_OPTION_KEEPALIVE	This option specifies that packets are to be sent to the remote system when no data is being exchanged to keep the connection active. This option is not necessary for most connections, particularly when the client will not be connected to the server for an extended period of time.
INET_OPTION_NODELAY	This option disables the Nagle algorithm. By default, small amounts of data written to the socket are buffered, increasing efficiency and reducing network congestion. However, this buffering can negatively impact the responsiveness of certain applications. This option disables this buffering and immediately sends data packets as they are written to the socket.
INET_OPTION_NOINHERIT	This option prevents the socket handle from being inherited by child processes created by the application. Using this option can mitigate situations in which a child process does not close the handle, leaving it open after the parent process has disconnected from the server.
INET_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will

	always be permitted. This option only affects secure connections using the TLS protocol.
INET_OPTION_SECURE	This option specifies that a secure connection should be established with the remote host. The connection will always default to using TLS 1.2 or later and the strongest cipher suites available on the client platform. This option may be automatically enabled if the URL scheme specifies a service which requires a secure connection. See the remarks below for more information.
INET_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
INET_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
INET_OPTION_FREETHREAD	This option specifies the socket returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the socket is synchronized across multiple threads.

Return Value

If the method succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **ConnectUrl** method provides a simplified interface which can be used to establish a connection using a URL. This method can only be used to establish connections using TCP and does not currently support the use of URLs to connect with a service which uses UDP. The general format of the URL should look like this:

```
[scheme]:// [[username : password] @] hostname [:port] / [path;parameters
...]
```

This method recognizes most standard URI schemes which use this format. The host name and port number specified in the URL will be used to establish a connection and the remaining information will be discarded. If the URL does not explicitly specify a port number, the default port number associated with the scheme will be used as the default value. For example, consider the following:

```
https://www.example.com
```

In this example, there is no port number specified; instead, the default port for the **https://** scheme

would be used, which is port 443. The host name **www.example.com** would be resolved into an IP address and the connection established on port 443. This method will also recognize a simpler format which only includes the host name and port number without a URI scheme, such as:

```
www.example.com:443
```

When used in this way, the port number must always be provided. Without a URI scheme or an explicit port number, the method cannot determine what port number should be used when establishing the connection. The same also applies if a custom, non-standard URI scheme is provided which is not recognized.

If the URI scheme specifies a secure protocol which requires implicit TLS, this method will automatically enable the INET_OPTION_SECURE option. For example, providing a URL which uses the **https://** scheme will automatically enable a secure connection regardless if the *dwOptions* parameter includes that option. If a URI scheme is used in conjunction with a port number associated with a secure service, security will also be enabled for that connection. For example:

```
http://www.example.com:443
```

The standard **http://** scheme is used which does not indicate a secure connection. However, since port 443 is the standard port designated for a secure HTTP connection, a secure connection will be enabled by default, even if INET_OPTION_SECURE has not been specified by the caller. Alternatively, if a custom port number is specified in the URL or the scheme is not recognized as one which requires implicit TLS, security options will not be automatically enabled for the connection.

The host name portion of the URL can be specified as either a domain name or an IP address. Because an IPv6 address can contain colon characters, you must enclose the entire address in bracket [] characters. If this is not done, this method will return an error indicating the port number is invalid. For example, the URL `https://[2001:db8:0:0:1::128]/` uses an IPv6 host address and this would be considered valid. Without the brackets, this URL would not be accepted.

Important: The URL provided to this method will only be used to establish a connection with a server. This is a general purpose method which does not enable support for any particular application protocol and all implementation details are the responsibility of your application. If you require higher-level support for a specific Internet protocol, the SocketTools API provides comprehensive collection of higher-level classes which can be used to access those services.

If you use the INET_OPTION_SECURE option to enable a secure connection, the connection will always use implicit TLS. This means a secure session will be initiated immediately after the socket connection has been established with the server. A common example of a service which uses implicit TLS is the HTTPS protocol. Another type of secure connection is one that uses explicit TLS. This is when the client establishes a normal (non-secure) connection with the server and then explicitly switches to using a secure connection, typically by sending a command. If the server you are connecting to requires explicit TLS, you should not specify the INET_OPTION_SECURE option. Instead, connect without this option and then call the **InetEnableSecurity** method when you are ready to initiate the TLS handshake.

To prevent this method from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling **InetConnectUrl** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the handle is released, only the owner may call methods using that handle. The ownership of the handle may be transferred from one thread to another using the

InetAttachThread method.

Specifying the INET_OPTION_FREETHREAD option enables any thread to call any method using the socket handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the socket is synchronized. If one thread calls a method in the library, it must ensure that no other thread will call another method at the same time using the same socket handle.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

CSocketWrench::CreateSecurityCredentials Method

```
BOOL CreateSecurityCredentials(
   DWORD dwProtocol,
   DWORD dwOptions,
   LPCTSTR lpszUserName,
   LPCTSTR lpszPassword,
   LPCTSTR lpszCertStore,
   LPCTSTR lpszCertName
);

BOOL CreateSecurityCredentials(
   LPCTSTR lpszCertStore,
   LPCTSTR lpszCertName
);

BOOL CreateSecurityCredentials(
   LPCTSTR lpszCertName
);
```

The **CreateSecurityCredentials** method creates security credentials for the client session.

Parameters

dwProtocol

A bitmask of supported security protocols. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_TLS	Either the TLS 1.2 or 1.3 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers which reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows
