This method works by sending the IDLE command to the server and starting a worker thread which monitors the connection and looks for untagged responses issued by the server. Events will be generated for EXISTS, EXPUNGE and RECENT messages. Note that some servers may periodically send untagged OK messages to the client, indicating that the connection is still active; these messages are explicitly ignored.

An application should never make an assumption about how a particular server may send update notifications to the client. Servers can be configured to use different intervals at which notifications are sent. For example, a server may send new message notifications immediately, but may periodically notify the client when a message has been expunged. Alternatively, a server may only send notifications at fixed intervals, in which case the client would not be notified of any new messages until the interval period is reached. It is not possible for a client to know what a particular server's update interval is. Applications that require that degree of control should not use the **Idle** method and should poll the server instead.

[OnUpdate Event](#)

Initialize Method

Initialize the control and validate the runtime license key.

Syntax

```
object.Initialize( [LicenseKey] )
```

Parameters

LicenseKey

An optional string value which specifies a runtime license key used to initialize the control. If the license key is omitted or passed as an empty string, a development license must be installed on the local system.

Return Value

A value of zero is returned if the control was initialized successfully. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

This method dynamically loads other system libraries and allocates thread local storage. In most cases, it is not necessary to call this method directly because it is automatically invoked when an instance of the control is created by the container. However, if the control is created dynamically using **CreateObject** or a similar method, this must be the first method that is called before you attempt to modify any property values or invoke other methods. Failure to initialize the control may result in subsequent errors and/or cause an exception to be raised.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the control will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the control was created.

If the control is being used within another DLL, it is important that you do not attempt to create an instance of the control or call the **Initialize** method from within the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is written in C++ and it is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for any static and global C++ objects and has the same restrictions.

Example

```
Set imapClient = CreateObject("SocketTools.ImapClient.12")

nError = imapClient.Initialize(strLicenseKey)
If nError > 0 Then
    MsgBox "Unable to initialize SocketTools component"
End
End If
```

[IsInitialized Property](#), [Uninitialize Method](#)

OpenMessage Method

Open a message on the server.

Syntax

object.OpenMessage([*MessageNumber*], [*MessagePart*], [*Offset*], [*Length*], [*Options*])

Parameters

MessageNumber

Number of message to retrieve. This value must be greater than zero. The first message in the mailbox is message number one. If this argument is omitted, the current message selected by the **Message** property will be opened.

MessagePart

The message part that will be retrieved. A value of zero specifies that the complete message should be returned. If the message is a multipart MIME message, message parts start with a value of one. If this argument is omitted, the complete contents of the message will be accessible.

Offset

The byte offset into the message. This parameter can be used in conjunction with the **Length** argument to return a specific part of a message. If this argument is omitted or a value of zero is specified, the server will return data from the beginning of the message.

Length

An optional integer value which specifies the maximum number of bytes the client wishes to read. To specify the entire message, from the offset specified by the **Offset** argument to the end of the message, use a value of -1. If this argument is omitted, the entire contents of the message will be returned, starting at the byte offset specified by the **Offset** argument. If both the **Offset** and **Length** arguments are omitted, the entire contents of the message will be returned.

Options

An optional integer value which specifies one or more options. This argument is constructed by using a bitwise operator with any of the following values:

Value	Description
imapSectionDefault	All headers and the complete body of the specified message or message part are to be retrieved. The client application is responsible for parsing the header block. If the message is a MIME multipart message and the complete message is returned, the application is responsible for parsing the individual message parts if necessary.
imapSectionHeader	All headers for the specified message or message part are to be retrieved. The client application is responsible for parsing the header block.
imapSectionMimeHeader	The MIME headers for the specified message or message are to be retrieved. Only those header fields which are used in MIME messages, such as Content-Type will be returned to the client. This is typically useful when processing the header for a multipart message which contains file attachments. The client application is responsible for parsing the header block.

imapSectionBody	The body of the specified message or message part is to be retrieved. For a MIME formatted message, this may include data that is uuencoded or base64 encoded. The application is responsible for decoding this data.
imapSectionPreview	The message header or body is being previewed and should not be marked as read by the server. This prevents the message from having the imapFlagSeen flag from being automatically set when the message data is retrieved.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **OpenMessage** method opens a message or a specific part of a multipart message in the current mailbox. The message data may also be limited a specific byte offset and length, which can be useful for previewing the contents. The client can then read the contents of the message using the **Read** method, and once all of the data has been read, the message should be closed by calling the **CloseMessage** method.

See Also

[CloseMessage Method](#), [GetMessage Method](#), [Read Method](#)

Read Method

Return data read from the server.

Syntax

object.Read(*Buffer*, [*Length*])

Parameters

Buffer

A buffer that the data will be stored in. If the variable is a **String** then the data will be returned as a string of characters. If the data returned by the server contains UTF-8 encoded text, it will automatically be converted to standard UTF-16 Unicode text. If you wish to read the data without conversion, provide a **Byte** array as the buffer.

Length

A numeric value which specifies the number of bytes to read. Its maximum value is $2^{31}-1 = 2147483647$. This argument is required to be present for string data. If a value is specified for this argument for other permissible types of data, and it is less than number of bytes that is determined by the control, then **Length** will override the internally computed value. If the argument is omitted, then the maximum number of bytes to read is determined by the size of the buffer.

Return Value

The number of bytes actually read from the server is returned by this method. If an error occurs, a value of -1 is returned.

Remarks

The **Read** method returns data that has been read from the server, up to the number of bytes specified. If no data is available to be read, an error will be generated if the control is non-blocking mode. If the control is in blocking mode, the program will wait until data is returned by the server or the connection is closed.

See Also

[IsConnected Property](#), [IsReadable Property](#), [Write Method](#), [OnRead Event](#), [OnWrite Event](#)

Refresh Method

Updates the list of available mailboxes.

Syntax

object.Refresh

Parameters

None.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **Refresh** method updates the list of mailboxes that may be selected by the client. The available mailboxes may be enumerated using the **Mailbox** property array, with the **Mailboxes** property returning the total number of mailboxes.

See Also

[Mailbox Property](#), [Mailboxes Property](#), [MailboxName Property](#), [ExamineMailbox Method](#), [RenameMailbox Method](#), [ReselectMailbox Method](#), [SelectMailbox Method](#)

RenameMailbox Method

Change the name of a mailbox.

Syntax

object.RenameMailbox(*OldName*, *NewName*)

Parameters

OldName

A string that specifies the name of the mailbox to be renamed on the server. The mailbox must exist on the server, otherwise an error will be returned.

NewName

A string that specifies the new name for the mailbox. An error will be returned if a mailbox with that name already exists.

Return Value

A value of zero is returned if the operation was successful, otherwise a non-zero error code is returned which indicates the cause of the failure.

Remarks

If the existing mailbox name contains inferior hierarchical names (mailboxes under the specified mailbox) then those mailboxes will also be renamed. For example, if the mailbox "Mail/Pictures" contains two mailboxes, "Personal" and "Work" and it is renamed to "Mail/Images" then the two mailboxes under it would be automatically renamed to "Mail/Images/Personal" and "Mail/Images/Work".

If the mailbox being renamed is the currently selected mailbox, the current mailbox will be unselected and any messages marked for deletion will be expunged. The new mailbox name will then automatically be re-selected. To prevent deleted messages from being removed from the mailbox prior to being renamed, use the **UnselectMailbox** method to unselect the current mailbox before calling **RenameMailbox**. Note that if the rename operation fails, the client may be left in an unselected state.

It is permitted to rename the special mailbox INBOX. In this case, the messages will be moved from the INBOX mailbox to the new mailbox. If the INBOX mailbox is currently selected, the new mailbox will not automatically be selected. INBOX will remain the selected mailbox.

See Also

[Mailbox Property](#), [Mailboxes Property](#), [MailboxName Property](#), [ExamineMailbox Method](#), [ReselectMailbox Method](#), [SelectMailbox Method](#)

ReselectMailbox Method

Reselects the current mailbox.

Syntax

object.ReselectMailbox

Parameters

None.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **ReselectMailbox** method forces the current mailbox to be reselected and updates those properties which return information about the mailbox, such as the **MailboxFlags** property. Deleted messages are not expunged from the mailbox and remain marked for deletion.

See Also

[MailboxName Property](#), [MailboxFlags Property](#), [MailboxUID Property](#), [ExamineMailbox Method](#), [SelectMailbox Method](#)

Reset Method

Reset the internal state of the control.

Syntax

object.Reset

Parameters

None.

Return Value

None.

Remarks

The **Reset** method resets the internal state of the control. Property values are initialized to their internal defaults, open network connections will be closed and any handles allocated by the control will be released.

See Also

[Cancel Method](#), [Initialize Method](#), [Uninitialize Method](#)

SearchMailbox Method

Search the current mailbox for messages that match the specified criteria.

Syntax

object.SearchMailbox(*Criteria*, *Messages*, [*CharacterSet*])

Parameters

Criteria

A string which consists of one or more keywords which are used to define the search criteria. The following keywords are recognized:

Keyword	Description
ANSWERED	Match those messages which have the imapFlagAnswered flag set.
BCC <i>address</i>	Match those messages which contain the specified address in the BCC header field.
BEFORE <i>date</i>	Match those messages which were added to the mailbox prior to the specified date.
BODY <i>string</i>	Match those messages where the body contains the specified string.
CC <i>address</i>	Match those messages which contain the specified address in the CC header field.
DELETED	Match those messages which have the imapFlagDeleted flag set.
DRAFT	Match those messages which have the imapFlagDraft flag set.
FLAGGED	Match those messages which have the imapFlagUrgent flag set.
FROM <i>address</i>	Match those messages which contain the specified address in the FROM header field.
HEADER <i>field string</i>	Match those messages which contain the string in the specified header field. If no string is specified, then all messages which contain the header will be matched.
LARGER <i>size</i>	Match those messages which are larger than the specified size in bytes.
NEW	Match those messages which have the imapFlagRecent flag set, but not the imapFlagSeen flag.
OLD	Match those messages which do not have the imapFlagRecent flag set.
ON <i>date</i>	Match those messages which were added on the specified date.
RECENT	Match those messages which have the imapFlagRecent flag set.
SEEN	Match those messages which have the imapFlagSeen flag set.
SENTBEFORE <i>date</i>	Match those messages whose Date header value is earlier than the specified date.
SENTON <i>date</i>	Match those messages whose Date header value is the same as the specified date.
SENTSINCE	Match those messages whose Date header value is later than the

<i>date</i>	specified date.
SINCE <i>date</i>	Match those messages added to the mailbox after the specified date.
SMALLER <i>size</i>	Match those messages which are smaller than the specified size in bytes.
SUBJECT <i>string</i>	Match those messages whose Subject header contains the specified string.
TEXT <i>string</i>	Match those messages whose headers or body contains the specified string.
TO <i>address</i>	Match those messages which contain the specified address in the TO header field.
UID <i>sequence</i>	Match those messages with unique identifiers in the sequence set.
UNANSWERED	Match those messages which do not have the imapFlagAnswered flag set.
UNDELETED	Match those messages which do not have the imapFlagDeleted flag set.
UNDRAFT	Match those messages which do not have the imapFlagDraft flag set.
UNFLAGGED	Match those messages which do not have the imapFlagUrgent flag set.
UNSEEN	Match those messages which do not have the imapFlagSeen flag set.

Messages

This argument must be passed as an array of integers which will contain the message numbers of those messages which match the search criteria. The size of the array determines the maximum number of matches that will be returned by the method. Note that the array must specify 32-bit integers. In Visual Basic, this means that the array would be typed as Long. In Visual Basic.NET, the array would be typed as Integer.

CharacterSet

An optional string which specifies the character set to use when searching the mailbox. If this argument is omitted, the default UTF-8 character set will be used. Note that not all servers support searches using anything but the default character set.

Return Value

This method will return the number of messages which were found to match the search criteria. If no messages match the criteria, then the return value will be zero. A return value of -1 indicates an error, and the specific error code can be determined by checking the **LastError** property.

Remarks

The **SearchMailbox** method is used to search a mailbox for messages which match a given criteria and return a list of the matching message numbers. The search criteria is composed of one or more search keywords and an optional value to match against. String searches are not case sensitive and partial matches in the message are returned. The message numbers returned by this method are only valid until the mailbox is expunged or another mailbox is selected.

In addition to the listed keywords, the keyword NOT may prefix a keyword to return those messages which do not match the search criteria. For example, "NOT TO user@domain.com" would return those messages which were not addressed to user@domain.com.

If multiple search keywords are specified, the result is the intersection of all those messages which meet the search criteria. For example, a search criteria of "DELETED SINCE 1-Jan-2010" would return

all those messages which are marked for deletion and were added to the mailbox after 1 January 2010.

Those search keywords which expect dates must be specified in format *dd-mmm-yyyy* where the month is the three letter abbreviation for the month name. Note that the internal date the message was added to the mailbox is not the same as the value of the Date header field in the message.

If the search keyword expects a string value and the string contains one or more spaces, you need to enclose the search string in quotes as part of the criteria string. For example, in Visual Basic you could use code like this:

```
strCriteria = "SUBJECT " + Chr(34) + "search string" + Chr(34)
```

The quotes around the search string prevents the server from interpreting it as a multiple search criteria to be evaluated. If you are using a search string provided by a user, it is recommended that you always enclose it in quotes to prevent any potential ambiguity in the search. Even if the search string does not contain any spaces, it is always safe to enclose it in quotes.

The UID keyword expects a one or more unique message identifiers. These values may provided as comma separated list, or a range delimited by a colon. For example, "UID 23000:24000" would return all those messages who have UIDs ranging from 23000 through to 24000.

See Also

[MailboxName Property](#), [ExamineMailbox Method](#), [SelectMailbox Method](#)

SelectMailbox Method

Selects the specified mailbox for read-write access.

Syntax

object.**SelectMailbox**(*MailboxName*)

Parameters

MailboxName

A string argument which specifies the name of the mailbox to be selected.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **SelectMailbox** method is used to select a mailbox in read-write mode. If the client has a different mailbox currently selected, that mailbox will be closed and any messages marked for deletion will be expunged. To prevent deleted messages from being removed from the previous mailbox, use the **UnselectMailbox** method prior to selecting the new mailbox.

The special case-insensitive mailbox name INBOX is used for new messages. Other mailbox names may or may not be case-sensitive depending on the IMAP server's operating system and implementation.

To access a mailbox in read-only mode, use the **ExamineMailbox** method.

See Also

[MailboxName Property](#), [CheckMailbox Method](#), [ExamineMailbox Method](#), [ReselectMailbox Method](#)

StoreMessage Method

Retrieve a message from the current mailbox and store it in a local file.

Syntax

object.StoreMessage(MessageNumber, FileName)

Parameters

MessageNumber

Number of message to retrieve. This value must be greater than zero. The first message in the mailbox is message number one.

FileName

A string which specifies the file that the message will be stored in. If the file does not exist, it will be created. If the file does exist, it will be overwritten with the contents of the message.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **StoreMessage** method retrieves a message from the server and stores it in a file on the local system. The contents of the message is stored as a text file, using the specified file name. This method will cause the current thread to block until the message transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

See Also

[GetMessage Method](#), [OpenMessage Method](#)

SubscribeMailbox Method

Subscribes the user to the specified mailbox.

Syntax

object.SubscribeMailbox(MailboxName)

Parameters

MailboxName

A string which specifies the name of the mailbox to subscribe to.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **SubscribeMailbox** method adds the specified mailbox to the current user's list of active or subscribed mailboxes. The user will remain subscribed to the mailbox across multiple sessions, until the **UnsubscribeMailbox** method is called to remove the mailbox from the subscription list.

Note that if a user subscribes to a mailbox and that mailbox is later renamed or deleted, the mailbox will not be automatically removed from the user's subscription list. To determine if the current mailbox is in the user's subscription list, check the **Subscribed** property.

See Also

[MailboxName Property](#), [Subscribed Property](#), [UnsubscribeMailbox Method](#)

UndeleteMessage Method

Removes the deletion flag for the specified message.

Syntax

object.UndeleteMessage(*MessageNumber*)

Parameters

MessageNumber

Number of message to undelete from the server. This value must be greater than zero. The first message in the mailbox is message number one.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **UndeleteMessage** method removes the deletion flag for the specified message in the current mailbox. To determine if a message has been marked for deletion, set the **Message** property to the message number and then check the value of the **MessageFlags** property to determine if the **imapFlagDeleted** bit flag has been set.

See Also

[MessageFlags Property](#), [DeleteMessage Method](#), [ReselectMailbox Method](#)

Uninitialize Method

Uninitialize the control and release any system resources that were allocated.

Syntax

object.Uninitialize

Parameters

None.

Return Value

None.

Remarks

The **Uninitialize** method terminates any connection established by the control and resets the internal state of the control. This method is not typically used because any resources that have been allocated by an instance of the control will automatically be released when it is destroyed.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the control will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the control was created. An application should only call the **Uninitialize** method if it has explicitly called the **Initialize** method.

See Also

[Initialize Method](#)

UnselectMailbox Method

Unselects the current mailbox.

Syntax

object.UnselectMailbox([*Expunge*])

Parameters

Expunge

An optional boolean argument which determines if deleted messages will be expunged from the mailbox. A value of true specifies that messages that have been marked for deletion will be removed from the mailbox. A value of False specifies that no messages will be removed from the mailbox. If this argument is omitted, the default action is to expunge deleted messages from the mailbox.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **UnselectMailbox** method unselects the current mailbox. Once the mailbox has been unselected, no messages in that mailbox can be accessed, and by default any messages which have been marked for deletion are removed.

See Also

[MailboxName Property](#), [ExamineMailbox Method](#), [SelectMailbox Method](#)

UnsubscribeMailbox Method

Unsubscribes the user from the specified mailbox.

Syntax

object.UnsubscribeMailbox(*MailboxName*)

Parameters

MailboxName

A string which specifies the name of the mailbox to unsubscribe from.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **UnsubscribeMailbox** method removes the specified mailbox from the current user's list of active or subscribed mailboxes. To determine if the current mailbox is in the user's subscription list, check the **Subscribed** property.

See Also

[MailboxName Property](#), [Subscribed Property](#), [SubscribeMailbox Method](#)

Write Method

Write data to the server.

Syntax

object.Write(*Buffer*, [*Length*])

Parameters

Buffer

A buffer variable that contains the data to be written to the server. If the variable is a **String** type, then the data will be written as a string of characters. This is the most appropriate data type to use because the server expects text data that consists of printable characters. If the string contains Unicode characters, it will be automatically converted to use standard UTF-8 encoding prior to being sent. If you wish to send the data without conversion, use a **Byte** array as the buffer instead of a **String** variable.

Length

A numeric value which specifies the number of bytes to write. Its maximum value is $2^{31}-1 = 2147483647$. If a value is specified for this argument and it is greater than the actual size of the buffer, then the **Length** argument will be ignored and the entire contents of the buffer will be written. If the argument is omitted, then the maximum number of bytes to write is determined by the size of the buffer.

Return Value

This method returns the number of bytes actually written to the server, or -1 if an error was encountered.

Remarks

The **Write** method sends the data in *buffer* to the server. If the connection is buffered, as is typically the case, the data is copied to the send buffer and control immediately returns to the program. If the control is blocking, the application will wait until the data can be sent. If the control is non-blocking and the write fails because it could not send all of the data to the server, the **OnWrite** event will be fired when the server can accept data again.

See Also

[IsConnected Property](#), [IsWritable Property](#), [Timeout Property](#), [Read Method](#), [OnWrite Event](#)

Internet Message Access Protocol Control Events

Event	Description
OnCancel	This event occurs when a blocking operation is canceled
OnConnect	This event occurs when a connection is established
OnDisconnect	This event occurs when a connection is terminated
OnError	This event occurs when a control error occurs
OnProgress	This event occurs during data transfer
OnRead	This event occurs when data is available to be read
OnTimeout	This event occurs when a blocking operation times out
OnUpdate	This event occurs when the server sends a mailbox update notification to the client
OnWrite	This event occurs when data can be written to the server

OnCancel Event

The **OnCancel** event is generated when a blocking operation is canceled.

Syntax

Sub *object_OnCancel* ([*Index As Integer*])

Remarks

This event occurs when a blocking operation on the socket, such as sending or receiving data, is canceled with the **Cancel** method. To assist in determining which operation was canceled, consult the **State** property.

See Also

[Cancel Method](#), [OnError Event](#), [OnTimeout Event](#)

OnCommand Event

The **OnCommand** event is generated when the client sends a command to the server and receives a reply indicating the results of that command.

Syntax

Sub *object_OnCommand*([*Index As Integer*], **ByVal** *ResultCode As Variant*, **ByVal** *ResultString As Variant*)

Remarks

The **OnCommand** event is generated when the client receives a reply from the server after some action has been taken. The **ResultCode** argument contains the numeric result code returned by the server. The result codes returned from the server fall into one of the following categories:

Value	Description
100-199	Positive preliminary result. This indicates that the requested action is being initiated, and the client should expect another reply from the server before proceeding.
200-299	Positive completion result. This indicates that the server has successfully completed the requested action.
300-399	Positive intermediate result. This indicates that the requested action cannot complete until additional information is provided to the server.
400-499	Transient negative completion result. This indicates that the requested action did not take place, but the error condition is temporary and may be attempted again.
500-599	Permanent negative completion result. This indicates that the requested action did not take place.

The **ResultString** argument contains the descriptive string returned by the server which describes the result. The string contents may vary depending on the type of server.

See Also

[ResultCode Property](#), [ResultString Property](#), [Command Method](#)

OnConnect Event

The **OnConnect** event is generated when a connection is established.

Syntax

Sub *object_OnConnect* ([*Index As Integer*])

Remarks

The **OnConnect** event is generated when a connection is made with a server as a result of a **Connect** method call. This event is only triggered when the **Blocking** property is set to False.

See Also

[Blocking Property](#), [Connect Method](#), [OnDisconnect Event](#), [OnWrite Event](#)

OnDisconnect Event

The **OnDisconnect** event is generated when a connection is terminated.

Syntax

Sub *object_OnDisconnect* ([*Index As Integer*])

Remarks

The **OnDisconnect** event is generated when the connection is terminated by the server. This event is only triggered when the **Blocking** property is set to False.

When the **OnDisconnect** event fires, it is possible that there may still be buffered data available to read from the server. Before disconnecting from the server, the application should attempt to read any remaining data until the **Read** method returns a value of zero, or returns an error indicating that the operation would block.

See Also

[Blocking Property](#), [IsConnected Property](#), [IsReadable Property](#), [Connect Method](#), [Disconnect Method](#), [Read Method](#), [OnConnect Event](#)

OnError Event

The **OnError** event is generated when a control error occurs.

Syntax

```
Sub object_OnError ( [Index As Integer,] ByVal ErrorCode As Variant, ByVal Description As Variant )
```

Remarks

This event occurs when an error occurs during a control action. Errors not generated by the control itself, such as errors related to the programming language or general component errors, do not trigger this event.

The ***ErrorCode*** argument specifies the last error that has occurred. If the error is network related, the error code values returned by the control correspond to those returned by the standard Windows Sockets library.

The ***Description*** argument is a string that describes the error.

See Also

[LastError Property](#), [LastErrorString Property](#), [ThrowError Property](#)

OnProgress Event

The **OnProgress** event is generated during data transfer.

Syntax

Sub *object_OnProgress* ([*Index As Integer*], **ByVal** *MessageNumber As Variant*, **ByVal** *MessageSize As Variant*, **ByVal** *MessageCopied As Variant*, **ByVal** *Percent As Variant*)

Remarks

The **OnProgress** event is generated during the transfer of data between the client and server, indicating the amount of data exchanged. For transfers of large amounts of data, this event can be used to update a progress bar or other user-interface control to provide the user with some visual feedback. The arguments to this event are:

MessageNumber

The number of the message that is being retrieved. If a message is being created, this argument will have a value of zero.

MessageSize

The size of the message being transferred in bytes. This value may be zero if the control cannot obtain the size of the message from the server.

MessageCopied

The number of bytes that have been transferred between the client and server.

Percent

The percentage of data that's been transferred, expressed as an integer value between 0 and 100, inclusive. If the size of the message on the server cannot be determined, this value will always be 100.

Note that this event is only generated when message data is transferred using the **CreateMessage**, **GetHeaders** or **GetMessage** methods. If the client is reading or writing the file data directly to the server using the **Read** or **Write** methods then the application is responsible for calculating the completion percentage and updating any user interface controls.

See Also

[Message Property](#), [MessagePart Property](#), [CreateMessage Method](#), [GetHeaders Method](#), [GetMessage Method](#)

OnRead Event

The **OnRead** event is generated when data is available to be read.

Syntax

Sub *object_OnRead* ([*Index As Integer*])

Remarks

The **OnRead** event is generated for non-blocking sockets when data is available to be read from the server. Use the **Read** method to read the data. This event is only triggered when the **Blocking** property is set to False.

See Also

[IsReadable Property](#), [Read Method](#), [Write Method](#), [OnWrite Event](#)

OnTimeout Event

The **OnTimeout** event is fired when a blocking operation times out.

Syntax

Sub *object_OnTimeout* ([*Index As Integer*])

Remarks

The **OnTimeout** event is generated when a blocking socket operation, such as sending or receiving data, times out. To determine which operation was in progress when the timeout occurred, consult the **State** property. This event is only triggered when the **Blocking** property is set to True.

See Also

[Timeout Property](#), [OnCancel Event](#)

OnUpdate Event

The **OnUpdate** event is generated when the server sends a mailbox update notification to the client.

Syntax

Sub *object_OnUpdate* ([*Index As Integer*], **ByVal** *UpdateType As Variant*, **ByVal** *MessageNumber As Variant*)

Remarks

The **OnUpdate** event is generated when the server sends a notification to the client that a new message has been stored in the mailbox, or when a message has been expunged from the mailbox. The arguments to this event are:

UpdateType

An integer value which specifies the type of update notification that has been sent by the server. It may be one of the following values:

Value	Description
imapUpdateUnknown	The server has sent an unrecognized notification message. The value of the MessageNumber argument is undefined for this type of notification. This does not necessarily reflect an error condition, as some servers may send additional notification messages beyond the standard EXISTS, EXPUNGE and RECENT messages. Most applications should ignore this type of notification.
imapUpdateMessage	The server has sent notification message to the client indicating that a new message has arrived. The MessageNumber argument will contain the message number for the new message. Typically this update notification occurs shortly after the new message has been stored in the current mailbox.
imapUpdateExpunge	The server has sent a notification message to the client indicating that a message has been removed from the current mailbox. The MessageNumber argument will contain the message number for the message that has been removed. It is recommended that the application re-examine the mailbox when this notification is received. Typically this notification is only sent periodically by the server, and may not be sent immediately after a message has been expunged from the mailbox.
imapUpdateMailbox	The server has sent notification message to the client indicating that the state of the mailbox has changed. The MessageNumber argument is not used with this notification. This message is sent periodically by the server and may not be sent immediately after a new message arrives or a message is flagged as unread. It is recommended that the application re-examine the mailbox when this notification is received.

MessageNumber

An integer value which specifies the message number associated with the status change. Note that this argument is not used with the **imapUpdateMailbox** notification and will contain a value of

zero.

This event is only generated when the **Idle** method has been used to enable mailbox status monitoring.

See Also

[Idle Method](#)

OnWrite Event

The **OnWrite** event is generated when data can be written to the server.

Syntax

Sub *object_OnWrite* ([*Index As Integer*])

Remarks

The **OnWrite** event is generated for non-blocking sockets when data can be written to the server after a previous attempt failed because it would cause the control to block. This event is only triggered when the **Blocking** property is set to False.

Control Information

Object Name	InternetMailCtl.InternetMail
File Name	CSIMCX12.OCX
Version	12.0.3024.1286
ProgID	SocketTools.InternetMail.12
ClassID	497D2D93-DF7A-41BE-B2E4-8B590BB26D5D
Threading Model	Apartment
Help File	CST12CTL.CHM
Dependencies	None
Standards	RFC 821, RFC 822, RFC 1034, RFC 1425, RFC 1869, RFC 1939 RFC 2045, RFC 2046, RFC 2047, RFC 2048, RFC 2821, RFC 3501

Overview

The Internet Mail ActiveX control had a comprehensive interface that provides everything required to incorporate email functionality in an application. The control implements the Simple Mail Transfer Protocol (SMTP) for sending messages, the Post Office Protocol (POP3) and Internet Message Access Protocol (IMAP) for retrieving messages from a mail serve. The Multipurpose Internet Mail Extensions (MIME) standard is implemented for composing and processing messages.

Many of the control's properties control the contents of a message, such as the list of recipients, the subject of the message and the message body. Methods are used to compose new messages, retrieve messages from a mail server and deliver messages to one or more recipients. Messages can also be managed on the mail server, or downloaded to the local system and stored in a file or a database record. The application has complete access to all of the headers in the message, and can create custom application-specific header fields if needed. Event notifications enable the application to provide the user with feedback, such as the progress of sending or retrieving a message. Additional features such as delivery status notification, support for relay servers and secure encrypted connections are easily implemented by setting a property or specifying an option when calling a method.

The control supports secure explicit and implicit connections using TLS 1.2 or later with client certificates for authentication. By simply setting a few properties, a secure connection using 256-bit AES encryption can be established, providing your application with the highest level of security available. Authentication is supported using both standard passwords and OAuth bearer tokens.

Requirements

The SocketTools ActiveX Edition components are self-registering controls that are compatible with any programming language that supports the Component Object Model (COM) and the ActiveX control specification. If you are using Visual Basic 6.0, Service Pack 6 (SP6) is required. We recommend installing all available updates for your development tools. Although the Visual Basic 6.0 runtime is supported on Windows 11, the IDE itself is no longer officially supported by Microsoft. Legacy IDEs and compilers may also require elevated (administrator) privileges to run properly.

The ActiveX controls are supported on Windows 7, Windows Server 2008 R2, and later versions of both desktop and server editions of Windows. For Windows 7, Service Pack 1 (SP1) is the minimum requirement. For Windows 8 systems, the 8.1 update must be installed. On ARM-based platforms, the minimum supported version is Windows 10 build 1709.

SocketTools includes components for both 32-bit (x86) and 64-bit (x64) Windows platforms. All modern versions of Windows are 64-bit, but we continue to include 32-bit components for compatibility with legacy development tools such as Visual Basic 6.0. We also provide native ARM64 ActiveX controls for systems running Windows on ARM. Note that 32-bit applications on ARM run using x86 emulation, and Microsoft no longer supports native ARM32 applications.

If you are using VBScript, Visual Basic for Applications (VBA), or another scripting environment on an ARM-based system, be aware that 64-bit hosts will require ARM64 components, while 32-bit hosts will use x86 components under emulation. This includes applications created with Visual Basic 6.0. To reduce deployment complexity and avoid confusion, SocketTools does not include ARM32 ActiveX controls in its standard redistribution packages but they are available on request for legacy or specialized scenarios.

Distribution

When you distribute an application that uses this control, you can either install the file in the same folder as your application executable or as a shared component in the appropriate system folder. If you install the control in the system folder, it is important that you distribute the correct version for the target platform and it must be registered. If you install the control in the same folder as your executable, it is recommended that you use registration-free activation or COM redirection to ensure that the correct version of the control is loaded by the application.

Internet Mail Control Properties

Property	Description
AllHeaders	Returns the complete RFC 822 header values for the current message
AllRecipients	Returns a comma-separated list of all message recipients
Attachment	Return the name of the attached file in the current message part
Bcc	Gets and sets the list of addresses that should receive a blind copy of the current message
BearerToken	Gets and sets the OAuth 2.0 bearer token used for authentication
Cc	Gets and sets the list of addresses that should receive a copy of the current message
CertificateExpires	Return the date and time that the server certificate expires
CertificateIssued	Return the date and time that the server certificate was issued
CertificateIssuer	Returns information about the organization that issued the server certificate
CertificateName	Gets and sets the common name for the client certificate
CertificatePassword	Gets and sets the password associated with the client certificate
CertificateStatus	Return the status of the server certificate
CertificateStore	Gets and sets the name of the client certificate store or file
CertificateSubject	Returns information about the organization to which the server certificate was issued
CertificateUser	Gets and sets the user that owns the client certificate
CipherStrength	Return the length of the key used by the encryption algorithm
ContentID	Gets and sets the content identifier for the selected message part
ContentLength	Returns the size of the data stored in the selected message part
ContentType	Gets and sets the content type of the selected message part
Date	Gets and sets the date for the current message
Domain	Gets and sets the local domain name
Encoding	Gets and sets the content encoding for the current message part
From	Gets and sets the address of the person who sent the message
HashStrength	Return the length of the message digest that was selected
IsBlocked	Determine if the control is blocked performing an operation
IsConnected	Determine if the control is connected to a server
IsInitialized	Determine if the control has been initialized
IsInitialized	Determine if the control has been initialized
LastError	Gets and sets the last error code
LastErrorString	Return a description of the last error that occurred
LastMessage	Return the number of the last message available on the server
Localize	Enable or disable message localization
Mailbox	Returns the name of the specified mailbox from a list of mailboxes on the server
Mailboxes	Returns the number of mailboxes available on the server
MailboxFlags	Returns one or more flags which identify characteristics of the current mailbox
MailboxName	Gets and sets the name of the current mailbox
MailboxSize	Return the size of the current mailbox in bytes
MailboxUID	Returns the unique identifier for the current mailbox
Mailer	Gets and sets the name of the mailer application
Message	Gets and sets the current message headers and text

MessageCount	Return the number of messages available on the server
MessageFlags	Returns one or more flags which identify characteristics of the current message
MessageID	Return a unique identifier for the current message
MessageIndex	Gets and sets the current message number on the server
MessagePart	Gets and sets the current part in a multipart message
MessageParts	Return the number of parts in the current message
MessageSize	Return the size of the current message in bytes
MessageText	Return or change the text in the current message part
MessageUID	Return the UID for the current message on the mail server
NameServer	Gets and sets the Internet address for a nameserver
NewMessages	Return the number of new messages available in the current mailbox
Organization	Return or change the name of the organization that created the message
Password	Gets and sets the password for the current user
Priority	Gets and sets the current message priority
RecentMessages	Returns the number of messages which have recently arrived in the mailbox
Recipient	Return the address of a message recipient
Recipients	Return the number of recipients for the current message
RelayServer	Gets and sets the host name or address of a relay server
RelayPort	Gets and sets the port number for the specified relay server
ReplyTo	Gets and sets the address of the person who should receive replies to this message
ReturnReceipt	Gets and sets the address of the person who should receive a message indicating that the message has been read
Secure	Specify if a connection to the server is secure
SecureCipher	Return the encryption algorithm used to establish the secure connection with the server
SecureHash	Return the message digest selected when establishing the secure connection with the server
SecureKeyExchange	Return the key exchange algorithm used to establish the secure connection with the server
SecureProtocol	Gets and sets the security protocol used to establish the secure connection with the server
ServerName	Gets and sets the host name of the current mail server
ServerPort	Gets and sets the port number for the current mail server
Subject	Gets and sets the subject of the current message
ThrowError	Enables or disables error handling by the application
Timeout	Gets and sets the amount of time until a blocking network operation is aborted
TimeZone	Gets and sets the current timezone offset in seconds
To	Gets and sets the recipient of the current message
Trace	Enable or disable network function level tracing
TraceFile	Return or specify the network function trace output file
TraceFlags	Gets and sets the current network function tracing flags
UnreadMessages	Returns the number of unread messages in the current mailbox
UserName	Gets and sets the current user name
Version	Return the current version of the control

AllHeaders Property

Returns the complete RFC 822 header values for the current message.

Syntax

object.AllHeaders

Remarks

The **AllHeaders** property will return all of the RFC 822 header values in a string. This includes the message headers that are most commonly referred to, such as the To, From and Subject headers. Each header and its value are separated by a colon, and terminated with a carriage return and linefeed (CRLF) pair.

The headers and their values returned by this property will not be identical to the header block in the original message. If a header value is split across multiple lines, the text returned by this property will be folded, with the complete header value on a single line of text and removing any extraneous whitespace. If the header value has been encoded by the mail client, this property will return the decoded value, not the original encoded value.

Data Type

String

See Also

[GetHeader](#), [SetHeader](#)

AllRecipients Property

Returns a comma-separated list of all message recipients.

Syntax

object.AllRecipients

Remarks

The **AllRecipients** property returns a string value that contains a comma-separated list of all message recipients. To individually enumerate through each of the recipient addresses, you can use the **Recipient** property array and **Recipients** property.

The string returned by this property will include those addresses specified by the **Bcc** property, even though they are not included in the message header.

Data Type

String

See Also

[Bcc Property](#), [Cc Property](#), [Recipient Property](#), [Recipients Property](#), [To Property](#), [ComposeMessage Method](#)

Attachment Property

Return the name of the attached file in the current message part.

Syntax

object.Attachment

Remarks

The **Attachment** property returns the name of the file attachment in the current part of a multipart message. When a new part is selected that contains an attached file, the **Attachment** property is updated to reflect the attached file's name. If the current message part does not contain a file attachment, this property will return an empty string.

Data Type

String

See Also

[AttachData Method](#), [AttachFile Method](#), [ExtractFile Method](#), [FindAttachment Method](#)

Bcc Property

Gets and sets the list of addresses that should receive a blind copy of the current message.

Syntax

object.Bcc [= *value*]

Remarks

The **Bcc** property is used to specify one or more addresses that a copy of the message will be delivered to. Note that these addresses are not included in the message header and cannot be viewed by the recipient.

Multiple addresses may be specified by separating them with a comma. Each address must conform to the standard Internet address format.

Data Type

String

See Also

[Cc Property](#), [From Property](#), [ReplyTo Property](#), [To Property](#)

BearerToken Property

Gets and sets the OAuth 2.0 bearer token for the current user.

Syntax

object.BearerToken [= *token*]

Remarks

The **BearerToken** property specifies the OAuth 2.0 bearer token used to authenticate the user. Assigning a value to this property will change the current authentication method to use OAuth 2.0.

You should only use an OAuth 2.0 authentication method if you understand the process of how to request the access token. Obtaining an bearer token requires registering your application with the mail service provider (e.g.: Microsoft or Google), getting a unique client ID associated with your application and then requesting the token using the appropriate scope for the service. Obtaining the initial token will typically involve interactive confirmation on the part of the user, requiring they grant permission to your application to access their mail account.

Your application should not store an OAuth 2.0 bearer token for later use. They have a relatively short lifespan, typically about an hour, and are designed to be used with that session. You should specify offline access as part of the OAuth 2.0 scope if necessary and store the refresh token provided by the service. The refresh token has a much longer validity period and can be used to obtain a new bearer token when needed.

If the current authentication method does not use OAuth 2.0, this property will return an empty string and you should check the value of the **Password** property to obtain the current user's password.

Data Type

String

See Also

[Password Property](#), [UserName Property](#), [Connect Method](#)

Cc Property

Gets and sets the list of addresses that should receive a copy of the current message.

Syntax

object.Cc [= *value*]

Remarks

The **Cc** property returns the list of addresses that received a copy of the current message. If there is no current message, or the Cc header field is not defined, then this property will return an empty string.

Setting the **Cc** property creates or changes the value of the Cc header field in the message and specifies additional recipients of the message. Multiple addresses may be specified by separating them with a comma. Each address must conform to the standard Internet address format.

Data Type

String

See Also

[Bcc Property](#), [From Property](#), [ReplyTo Property](#), [To Property](#)

CertificateExpires Property

Return the date and time that the server certificate expires.

Syntax

object.CertificateExpires

Remarks

The **CertificateExpires** property returns the date and time that the server certificate expires. This property will return an empty string if a secure connection has not been established with the server.

Data Type

String

See Also

[CertificateIssued Property](#), [CertificateIssuer Property](#), [CertificateStatus Property](#), [CertificateSubject Property](#), [Secure Property](#)

CertificateIssued Property

Return the date and time that the server certificate was issued.

Syntax

object.CertificateIssued

Remarks

The **CertificateIssued** property returns the date and time that the server certificate was issued. This property will return an empty string if a secure connection has not been established with the server.

Data Type

String

See Also

[CertificateExpires Property](#), [CertificateIssuer Property](#), [CertificateStatus Property](#), [CertificateSubject Property](#), [Secure Property](#)

CertificateIssuer Property

Returns information about the organization that issued the server certificate.

Syntax

object.CertificateIssuer

Remarks

The **CertificateIssuer** property returns a string that contains information about the organization that issued the server certificate. The string value is a comma separated list of tagged name and value pairs. In the nomenclature of the X.500 standard, each of these pairs are called a relative distinguished name (RDN), and when concatenated together, forms the issuer's distinguished name (DN). For example:

C=US, O="RSA Data Security, Inc.", OU=Secure Server Certification Authority

To obtain a specific value, such as the name of the issuer or the issuer's country, the application must parse the string returned by this property. Some of the common tokens used in the distinguished name are:

Name	Description
C	The ISO standard two character country code
S	The name of the state or province
L	The name of the city or locality
O	The name of the company or organization
OU	The name of the department or organizational unit
CN	The common name; with X.509 certificates, this is the domain name of the site the certificate was issued for

This property will return an empty string if a secure connection has not been established with the server.

Example

The following example demonstrates how to extract the value of a relative distinguished name token:

```
Function GetCertNameValue(ByVal strValue As String, ByVal strFieldName As String)
As String
    Dim strFieldValue As String
    Dim cchValue As Long
    Dim cchFieldName As Long
    Dim nOffset As Long

    GetCertNameValue = ""
    cchValue = Len(strValue)
    cchFieldName = Len(strFieldName)

    If cchValue = 0 Or cchFieldName = 0 Then
        Exit Function
    End If

    nOffset = InStr(strValue, strFieldName & "=")
```

```
If nOffset > 0 Then
```

```
'  
' If the field name was found in the string, then  
' remove everything to the left of the token from  
' the string  
,
```

```
strFieldValue = Right(strValue, cchValue - (nOffset + cchFieldName))
```

```
'  
' If the value is quoted, then strip off the leading  
' quote and look for the ending quote in the string;  
' otherwise look for the comma that marks the end of  
' the field name/value pair  
,
```

```
If Left(strFieldValue, 1) = Chr(34) Then  
    strFieldValue = Right(strFieldValue, Len(strFieldValue) - 1)  
    nOffset = InStr(strFieldValue, Chr(34))
```

```
Else  
    nOffset = InStr(strFieldValue, ",")  
End If
```

```
'  
' If the offset is 0, then the name/value pair is  
' the last token in the string; otherwise, remove  
' everything to the right of that position  
,
```

```
If nOffset > 0 Then  
    strFieldValue = Left(strFieldValue, nOffset - 1)  
End If
```

```
GetCertNameValue = strFieldValue  
End If
```

```
End Function
```

This function could then be used to return the name of the company who issued the server certificate:

```
Dim strIssuer As String  
Dim strCompanyName As String  
  
strIssuer = InternetMail1.CertificateIssuer  
If Len(strIssuer) = 0 Then  
    MsgBox "A secure connection has not been established"  
Else  
    strCompanyName = GetCertNameValue(strIssuer, "O")  
    MsgBox "This certificate was issued by " & strCompanyName  
End If
```

Data Type

String

See Also

[CertificateExpires Property](#), [CertificateIssued Property](#), [CertificateStatus Property](#), [CertificateSubject Property](#), [Secure Property](#)

CertificateName Property

Gets and sets the common name for the client certificate.

Syntax

object.CertificateName [= *name*]

Remarks

This property sets the common name or friendly name of the certificate that should be used to establish the connection with the server. It is only required that you set this property value if the server requires a client certificate for authentication. If this property is not set, a client certificate will not be provided to the server. If a certificate name is specified, the certificate must have a private key associated with it, otherwise the connection attempt will fail because the control will be unable to create a security context for the session.

Certificates may be installed and viewed on the local system using the Certificate Manager that is included with the Windows operating system. For more information, refer to the documentation for the Microsoft Management Console.

Data Type

String

See Also

[CertificateStore Property](#), [Secure Property](#)

CertificatePassword Property

Gets and sets the password associated with the client certificate.

Syntax

object.CertificatePassword [= *password*]

Remarks

This property sets the password that should be used to access a certificate in the specified certificate store. It is only required when the **CertificateStore** property specifies a file that contains a certificate and private key in PKCS #12 format.

Data Type

String

See Also

[CertificateName Property](#), [CertificateStore Property](#), [Secure Property](#)

CertificateStatus Property

Return the status of the server certificate.

Syntax

object.CertificateStatus

Remarks

The **CertificateStatus** property may return one of the following values:

Value	Description
mailCertificateNone	No certificate information is available. A secure connection was not established with the server.
mailCertificateValid	The certificate is valid.
mailCertificateNoMatch	The certificate is valid, however the domain name specified in the certificate does not match the domain name of the site that the client has connected to. This is typically the case if the ServerName property is set to an IP address rather than a host name. It is recommended that the client examine the CertificateSubject property to determine the domain name of the site that the certificate was issued for.
mailCertificateExpired	The certificate has expired and is no longer valid. The client can examine the CertificateExpires property to determine when the certificate expired.
mailCertificateRevoked	The certificate has been revoked and is no longer valid. It is recommended that the client application immediately terminate the connection if this status is returned.
mailCertificateUntrusted	The certificate has not been issued by a trusted authority, or the certificate is not trusted on the local host. It is recommended that the client application immediately terminate the connection if this status is returned.
mailCertificateInvalid	The certificate is invalid. This typically indicates that the internal structure of the certificate is damaged. It is recommended that the client application immediately terminate the connection if this status is returned.

This property value should be checked after the connection to the server has completed, but prior to beginning a transaction. If a secure connection has not been established, this property will return a value of zero.

Data Type

String

See Also

[CertificateExpires Property](#), [CertificateIssued Property](#), [CertificateIssuer Property](#), [CertificateSubject Property](#), [Secure Property](#)

CertificateStore Property

Gets and sets the name of the client certificate store or file.

Syntax

object.CertificateStore [= *store*]

Remarks

This property sets the name of the certificate store that contains the client certificate that should be used when establishing a secure connection with the server. The certificate may either be stored in the registry or in a file. If the certificate is stored in the registry, then this property should be set to one of the following predefined values:

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. If a certificate store is not specified, this is the default value that is used.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

In most cases the client certificate will be installed in the user's personal certificate store, and therefore it is not necessary to set this property value because that is the default location that will be used to search for the certificate. This property is only used if the **CertificateName** property is also set to a valid certificate name.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU" for the current user, or "HKLM" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, it will default to the certificate store for the current user.

This property may also be used to specify a file that contains the client certificate. In this case, the property should specify the full path to the file and must contain both the certificate and private key in PKCS #12 format. If the file is protected by a password, the **CertificatePassword** property must also be set to specify the password.

Data Type

String

See Also

[CertificateName Property](#), [CertificatePassword Property](#), [Secure Property](#)

CertificateSubject Property

Returns information about the organization that the server certificate was issued to.

Syntax

`object.CertificateSubject`

Remarks

The **CertificateSubject** property returns a string that contains information about the organization that the server certificate was issued for. The string value is a comma separated list of tagged name and value pairs. In the nomenclature of the X.500 standard, each of these pairs are called a relative distinguished name (RDN), and when concatenated together, forms the subject's distinguished name (DN). For example:

C=US, O="RSA Data Security, Inc.", OU=Secure Server Certification Authority

To obtain a specific value, such as the name of the issuer or the issuer's country, the application must parse the string returned by this property. Some of the common tokens used in the distinguished name are:

Name	Description
C	The ISO standard two character country code
S	The name of the state or province
L	The name of the city or locality
O	The name of the company or organization
OU	The name of the department or organizational unit
CN	The common name; with X.509 certificates, this is the domain name of the site the certificate was issued for

This property will return an empty string if a secure connection has not been established with the server.

Data Type

String

See Also

[CertificateExpires Property](#), [CertificateIssued Property](#), [CertificateIssuer Property](#), [CertificateStatus Property](#), [Secure Property](#)

CertificateUser Property

Gets and sets the user that owns the client certificate.

Syntax

object.CertificateUser [= *username*]

Remarks

This property sets the name of the user that owns the client certificate that will be used to establish a secure connection with the server. If this property is not set, the certificate store for the current user will be used when searching for the certificate. If this property is used to specify another user, the process must have the appropriate permission to access the registry location that contains the client certificate. On Windows Vista and later versions of the operating system, this requires that the process run with elevated privileges.

Data Type

String

See Also

[CertificateName Property](#), [CertificateStore Property](#), [Secure Property](#)

CipherStrength Property

Return the length of the key used by the encryption algorithm.

Syntax

object.CipherStrength

Remarks

The **CipherStrength** property returns the number of bits in the key used to encrypt the secure data stream. Common values returned by this property are 128 and 256. A key length of 40-bits or 56-bits is considered to be insecure, and subject to brute force attacks. 128-bit and 256-bit keys are considered secure. If this property returns a value of 0, this means that a secure connection has not been established with the server.

Data Type

Integer (Int32)

See Also

[HashStrength Property](#), [Secure Property](#), [SecureCipher Property](#), [SecureHash Property](#), [SecureKeyExchange Property](#), [SecureProtocol Property](#)

ContentID Property

Gets and sets the content identifier for the selected message part.

Syntax

object.ContentID [= *value*]

Remarks

The **ContentID** property returns the unique content identifier string for the current message part. This multipart header field is not commonly used, and if undefined, will return an empty string. If set, this will change the value of the Content-ID header field in the current message part.

Data Type

String

See Also

[ContentLength Property](#), [ContentType Property](#)

ContentLength Property

Returns the size of the data stored in the selected message part.

Syntax

object.ContentLength

Remarks

The **ContentLength** property returns the size of the current message part in bytes. This property is read-only, and is automatically updated when the current message part changes.

Data Type

Integer (Int32)

See Also

[ContentID Property](#), [ContentType Property](#)

ContentType Property

Gets and sets the content type of the selected message part.

Syntax

`object.ContentType [= value ]`

Remarks

The **ContentType** property returns the MIME type for the currently selected message part. The type string consists of a primary type and secondary sub-type separated by a slash, followed by one or more optional parameters delimited by semi-colons. For example, this is a common content type for text messages:

text/plain; charset=utf-8

The **text** designation indicates that this message part contains readable text, and the **plain** sub-type indicates that the text does not contain any special encoding. The optional parameter which follows the content type provides additional information about the content. In this example, it specifies which character set should be used to display the text. The two common character sets used are UTF-8 and US-ASCII.

There are seven predefined, standard content types, each with their own sub-types. The following table lists these types, along with some common sub-types that are found in messages:

Type	Sub-Types	Description
text	plain, richtext, html	Indicates that the message part contains text. This is the most common type found in mail messages; if no content type is explicitly defined, then it is assumed to be plain text.
image	gif, jpeg	Indicates that the message part contains a graphics image.
audio	basic, aiff, wav	Indicates that the message part contains audio data; the basic sub-type is 8-bit PCM encoded audio (commonly found with the .au filename extension).
video	mpeg, avi	Indicates that the message part contains a video clip in the specified format.
application	octet-stream	Indicates that the message part contains application specific data, typically used with the octet-stream sub-type to indicate binary file attachments for executable programs, compressed file archives, etc.
message	rfc822	Indicates that the message part contains a complete RFC 822 compliant message, complete with headers.
multipart	mixed, alternative	Indicates that this is part of a message that contains multiple parts with different content types.

The three most common content types that are used in applications are text/plain for the mail message body, application/octet-stream for binary file attachments and multipart/mixed for messages that contain both text and attached files. For more information about the different content types, refer to the Multipurpose Internet Mail Extensions (MIME) standards document RFC 1521.

Data Type

String

See Also

[ContentID Property](#), [ContentLength Property](#)

Date Property

Gets and sets the date for the current message.

Syntax

object.Date [= *value*]

Remarks

The **Date** property returns the value of the Date header field in the current message. Setting this property causes the Date field to be updated with the specified value. When setting the date, any one of the following formats may be used:

Format	Example
mm/dd/yy[yy] hh:mm[:ss]	03/01/98 12:00
yy[yy]/mm/dd hh:mm[:ss]	98/03/01 12:00
dd mmm yy[yy] hh:mm[:ss]	01 Mar 1998 12:00:00
mmm dd yy[yy] hh:mm[:ss]	Mar 01 1998 12:00:00

Any extraneous information that may be included in the date string, such as the day of the week, is ignored. In addition to the date and time, the string may also include a time zone specification at the end. If no time zone is specified, the current time zone is used.

When specifying a time zone, the value should either be prefixed by a plus sign (+) to indicate that the time zone is to the east of GMT, or a minus sign (-) to indicates that it's to the west. Four digits follow, with the first two indicating the number of hours east or west of GMT, and the last two digits indicating the number of minutes. Therefore, a value of -0800 means that the time zone is eight hours to the west of GMT, or in other words, the Pacific time zone. Regardless of the format of the string assigned to the property, it always returns the date in the same standard format.

Note that the **Localize** property affects how dates are processed by the control. If enabled, dates are automatically adjusted for the local time zone. By default, localization is disabled.

Data Type

String

See Also

[Localize Property](#)

Domain Property

Gets and sets the local domain name.

Syntax

object.Domain [= *value*]

Remarks

The **Domain** property specifies the domain name of the local host, and is used to identify the current system when sending messages. If this property is not defined, then the local host name will be used.

Note that explicitly setting the **Domain** property to a value that does not match your local host name may cause some mail servers to reject any messages that you attempt to send.

Data Type

String

Encoding Property

Gets and sets the content encoding for the current message part.

Syntax

object.Encoding [= *value*]

Remarks

The **Encoding** property returns a string which specifies the method used for encoding the current message part. Setting this property causes the Content-Transfer-Encoding header value to be updated. The following values are commonly used:

Type	Description
7bit	The default transfer encoding type, which consists of printable ASCII characters.
8bit	Printable ASCII characters, including those characters with the high-bit set (as is common with the ISO Latin-1 character set); this encoding type is not commonly used.
base64	The transfer encoding type commonly used to convert binary data into 7-bit ASCII characters so that it may be transported safely through the mail system.
binary	All characters; binary transfer encoding is rarely used.
quoted-printable	Printable ASCII characters, with non-printable or extended characters represented using their hexadecimal equivalents.
x-uuencode	A transfer encoding type similar in function to the base64 encoding method.

Note that setting this property only updates the Content-Transfer-Encoding header value. To control the actual encoding method used when attaching a file, see the **AttachFile** method.

Data Type

String

See Also

[ContentLength Property](#), [ContentType Property](#), [ExtractFile Method](#), [AttachFile Method](#)

From Property

Gets and sets the address of the person who sent the message.

Syntax

object.From [= *value*]

Remarks

The **From** property returns the address of the person who sent the message. Setting the property causes the From header field in the current message to be updated with the new value.

Data Type

String

See Also

[Bcc Property](#), [Cc Property](#), [ReplyTo Property](#), [To Property](#)

HashStrength Property

Return the length of the message digest that was selected.

Syntax

object.HashStrength

Remarks

The **HashStrength** property returns the number of bits used in the message digest (hash) that was selected. Common values returned by this property are 128 and 160. If this property returns a value of 0, this means that a secure connection has not been established with the server.

Data Type

Integer (Int32)

See Also

[CipherStrength Property](#), [Secure Property](#), [SecureCipher Property](#), [SecureHash Property](#), [SecureKeyExchange Property](#), [SecureProtocol Property](#)

IsBlocked Property

Determine if the control is blocked performing an operation.

Syntax

object.IsBlocked

Remarks

The **IsBlocked** property returns True if the specified control is blocked performing an operation. Because the Windows Sockets API only permits one blocking operation per thread of execution, this property can be used to ensure that another blocking operation is not in progress at the time.

If this property returns False, this means there are no blocking operations on the current thread at that time. If the property returns True, this tells you that you the control is already performing a blocking operation.

Data Type

Boolean

See Also

[LastError Property](#)

IsConnected Property

Determine if the control is connected to a server.

Syntax

object.IsConnected

Remarks

The **IsConnected** read-only property is set to a value of True if the control is connected with a remote host, otherwise the property has a value of false.

Data Type

Boolean

See Also

[Connect Method](#), [Disconnect Method](#)

IsInitialized Property

Determine if the control has been initialized.

Syntax

object.IsInitialized

Remarks

The **IsInitialized** property is used to determine if the current instance of the control has been initialized properly. Normally this is done automatically when the control is loaded, however there are circumstances where the control may not be able to initialize itself. If this property returns **False**, the application must call the **Initialize** method to initialize the control before performing any other operation.

The most common reason that the control may not initialize correctly is that no valid development or runtime license key can be found or the license key that was provided is invalid. It may also indicate a problem with the system configuration or user access rights, such as not being able to load the required networking libraries or not being able to access the system registry.

Data Type

Boolean

See Also

[Initialize Method](#)

LastError Property

Gets and sets the last error code.

Syntax

object.LastError [= *value*]

Remarks

The **LastError** property can be read to determine the last error that occurred for this instance of the object. If a value is assigned to this property, it must either be zero (to clear the error) or a valid error code.

Data Type

Integer (Int32)

See Also

[OnError Event](#)

LastErrorString Property

Return a description of the last error that occurred.

Syntax

object.LastErrorString

Remarks

The **LastErrorString** property returns a string that contains a description of the last error that occurred.

Data Type

String

See Also

[LastError Property](#)

LastMessage Property

Return the number of the last message available on the server.

Syntax

object.LastMessage

Remarks

The **LastMessage** property returns the last message available on the server. Note that unlike the **MessageCount** property, this value remains constant even when a message is deleted.

Data Type

Integer (Int32)

See Also

[Message Property](#), [MessageCount Property](#), [MessageSize Property](#)

LocalAddress Property

Return the Internet address of the local host.

Syntax

object.LocalAddress

Remarks

The **LocalAddress** property returns the Internet address of the local host as a string in dotted notation. If there is an active connection to a server, then the return value will depend on the network interface that was used to establish the connection. If there isn't a connection, then the default address for the local host will be returned.

Data Type

Integer (Int32)

See Also

[LocalName Property](#)

Localize Property

Enable or disable message localization.

Syntax

object.**Localize** [= { True | False }]

Remarks

The **Localize** property is used to enable or disable localization features of the object. Currently this only affects the way in which dates are processed. If set to True, the date and time will be adjusted for the local time zone when setting and reading the **Date** property. The default value for this property is False.

Data Type

Boolean

See Also

[Date Property](#)

LocalName Property

Return the Internet domain name of the local host.

Syntax

object.LocalName

Remarks

The **LocalName** property returns the Internet domain name for the local host. If there is an active connection to a server, then the domain name will depend on the network interface that was used to establish the connection. If there isn't a connection, then the default domain name for the local host will be returned.

Data Type

String

See Also

[LocalAddress Property](#)

Mailbox Property

Returns the name of the specified mailbox from a list of mailboxes on the server.

Syntax

object.Mailbox(*Index*)

Remarks

The **Mailbox** property array is used to enumerate the available mailboxes on the IMAP server. This is a zero-based array, which means that the index value for the first mailbox is zero. The total number of mailboxes that are available on the server is returned by the **Mailboxes** property.

This property should only be referenced when connected to an IMAP server.

Data Type

String

Example

The following example demonstrates how to use the **Mailbox** property array to populate a listbox that contains the names of the available mailboxes:

```
For nIndex = 0 To InternetMail.Mailboxes - 1
    List1.AddItem InternetMail.Mailbox(nIndex)
Next
```

See Also

[Mailboxes Property](#), [MailboxFlags Property](#), [MailboxName Property](#), [MailboxUID Property](#)

Mailboxes Property

Returns the number of mailboxes available on the server.

Syntax

object.Mailboxes

Remarks

The **Mailboxes** property returns the total number of mailboxes available to the current account on the server. This property can be used in conjunction with the **Mailbox** property array to enumerate the names of all of the mailboxes which can be selected by the client.

This property should only be referenced when connected to an IMAP server.

Data Type

Integer (Int32)

Example

The following example demonstrates how to use the **Mailboxes** property to populate a listbox that contains the names of the available mailboxes:

```
For nIndex = 0 To InternetMail.Mailboxes - 1
    List1.AddItem InternetMail.Mailbox(nIndex)
Next
```

See Also

[Mailbox Property](#), [MailboxFlags Property](#), [MailboxName Property](#), [MailboxUID Property](#)

MailboxFlags Property

Returns one or more flags which identify characteristics of the current mailbox.

Syntax

object.MailboxFlags

Remarks

The **MailboxFlags** property returns information about the currently selected mailbox. The value returned is one or more of the following bit flags:

Value	Description
mailFlagNoInferiors	The mailbox does not contain any child mailboxes. In the IMAP protocol, these are referred to as inferior hierarchical mailbox names.
mailFlagMarked	The mailbox is marked as being of interest to a client. If this flag is used, it typically means that the mailbox contains messages. An application should not depend on this flag being present for any given mailbox. Some IMAP servers do not support marked or unmarked flags for mailboxes.
mailFlagUnmarked	The mailbox is marked as not being of interest to a client. If this flag is used, it typically means that the mailbox does not contain any messages. An application should not depend on this flag being present for any given mailbox. Some IMAP servers do not support marked or unmarked flags for mailboxes.

Note that this property should only be used when connected to a mail server using the IMAP4 protocol.

Data Type

Integer (Int32)

Example

The following example demonstrates how to check the **MailboxFlags** property to see if the mailbox contains any child mailboxes:

```
If (InternetMail.MailboxFlags And mailFlagNoInferiors) <> 0 Then
    MsgBox "This mailbox does not contain any child mailboxes"
End If
```

See Also

[Mailbox Property](#), [Mailboxes Property](#), [MailboxName Property](#), [MailboxUID Property](#)

MailboxName Property

Gets and sets the name of the current mailbox.

Syntax

object.MailboxName [= *mailbox*]

Remarks

The **MailboxName** property returns the name of the currently selected mailbox. If no mailbox has been selected by the client, this property will return an empty string. This property is only valid when connected to an IMAP server.

Setting the **MailboxName** property will select a new mailbox in read-write mode. If the client has a different mailbox currently selected, that mailbox will be closed and any messages marked for deletion will be expunged. To prevent deleted messages from being removed from the previous mailbox, call the **UnselectMailbox** method prior to selecting the new mailbox. Setting the **MailboxName** property to an empty string will cause the current mailbox to be unselected, and a new mailbox will not be selected. Before the application can access any messages, it must select a new mailbox.

Selecting a new mailbox will automatically update those properties which provide information about the current mailbox, such as the **MailboxFlags** and **MailboxUID** properties. If an application wishes to update the information for the current mailbox, simply set the **MailboxName** property again with the same mailbox name. Note that this will not cause any messages marked for deletion to be expunged.

The special case-insensitive mailbox name INBOX is used for new messages. Other mailbox names may or may not be case-sensitive depending on the IMAP server's operating system and implementation.

If the mailbox name contains international characters then it is automatically encoded using a modified version of UTF-7 encoding. For example, if a mailbox is named "Håndskrift", the mailbox name created on the server will be the string "H&AOU-ndskrift". The control will automatically decode UTF-7 encoded mailbox names, making the conversion transparent to the application.

Data Type

String

See Also

[Mailbox Property](#), [Mailboxes Property](#), [MailboxFlags Property](#), [MailboxUID Property](#), [SelectMailbox Method](#), [UnselectMailbox Method](#)

MailboxSize Property

Return the size of the current mailbox in bytes.

Syntax

object.MailboxSize

Remarks

The **MailboxSize** property returns the combined size of all of the available messages in the current mailbox.

Reading this property may require a significant amount of time to calculate the mailbox size if there are a large number of messages in the mailbox. Because it can potentially result in long delays, it is not recommended that an application calculate the mailbox size unless it is absolutely necessary.

Data Type

Integer (Int32)

MailboxUID Property

Returns the unique identifier for the current mailbox.

Syntax

object.MailboxUID

Remarks

The **MailboxUID** property returns an integer value which uniquely identifies the mailbox and corresponds to the UIDVALIDITY value returned by the IMAP server. The actual value is determined by the server and should be considered opaque. The protocol specification requires that a mailbox's UID must not change unless the mailbox contents are modified or existing messages in the mailbox have been assigned new UIDs.

An application can use the **MailboxUID** property value in combination with the **MessageUID** property in order to uniquely identify a message on the server. However, the application must take into consideration that the IMAP server can reassign new message UIDs when the mailbox is modified. If the mailbox and message UIDs are being stored on the local system to track what messages have been retrieved from the server, the application must check the UID of the mailbox whenever it is selected. If the mailbox UID has changed, this means that the UIDs for the messages in that mailbox may have changed. The client should resynchronize with the server, and update its local copy of that mailbox.

Data Type

Integer (Int32)

See Also

[Mailbox Property](#), [Mailboxes Property](#), [MailboxFlags Property](#), [MailboxName Property](#)

Mailer Property

Gets and sets the name of the mailer application.

Syntax

object.**Mailer** [= *value*]

Remarks

The **Mailer** property returns the value of the X-Mailer header field in the current message. This is typically used to identify the application that created the message, however it is not required that this be specified. If the header field is not present in the message, this property will return an empty string. Setting this property will change the value of the X-Mailer header. If the property is set to an empty string, the header will be removed from the message.

Data Type

String

See Also

[GetHeader Method](#), [SetHeader Method](#)

Message Property

Gets and sets the current message headers and text.

Syntax

object.**Message** [= *value*]

Remarks

The **Message** property returns the current message, including the headers and all message parts, as a string. Setting this property will cause the current message to be cleared and replaced by the new value. The string contents must follow the standard specifications for a message. If the property is set to an empty string, the current message is cleared.

Note that setting the **Message** property will cause the value of the **Bcc** property to be reset to an empty string.

Data Type

String

MessageCount Property

Return the number of messages available on the server.

Syntax

object.MessageCount

Remarks

The **MessageCount** property returns the number of messages available to be retrieved from the mail server. When a message is deleted from the mailbox, this value will decrease. To determine the highest valid message number, regardless of any deleted messages, use the **LastMessage** property.

Data Type

Integer (Int32)

See Also

[LastMessage Property](#), [Message Property](#), [MessageSize Property](#)

MessageFlags Property

Returns one or more flags which identify characteristics of the current message.

Syntax

`object.MessageFlags [= flags ]`

Remarks

The **MessageFlags** property returns information about the currently selected message specified by the **MessageIndex** property. The value returned is one or more of the following bit flags:

Value	Value	Description
mailFlagNone	No flags have been set for the current message	
mailFlagAnswered	The message has been answered	
mailFlagDraft	The message is a draft copy and has not been delivered	
mailFlagUrgent	The message has been flagged for urgent or special attention	
mailFlagSeen	The message has been read	
mailFlagRecent	The message has been added to the mailbox recently	
mailFlagDeleted	The message has been marked for deletion	

Setting the **MessageFlags** property changes the flags for the currently selected message. Multiple bit flags can be combined using the bitwise Or operator. An application can test if a flag is set by using the bitwise And operator.

Note that this property should only be used when connected to a mail server using the IMAP4 protocol.

Data Type

Integer (Int32)

Example

The following example demonstrates how to check the **MessageFlags** property to see if the message has been marked for deletion, and if it has, to clear the flag so that it will not be deleted when the mailbox is unselected:

```
If (InternetMail.MessageFlags And mailFlagDeleted) <> 0 Then
    InternetMail.MessageFlags = InternetMail.MessageFlags And Not mailFlagDeleted
End If
```

See Also

[MessageCount Property](#), [MessageIndex Property](#), [MessagePart Property](#), [MessageParts Property](#), [MessageSize Property](#), [MessageUID Property](#), [GetMessage Method](#)

MessageID Property

Return a unique identifier for the current message.

Syntax

object.MessageID

Remarks

The **MessageID** property returns the value of the Message-ID header field, a string which is assigned by the mail server to uniquely identify the current message.

Data Type

String

See Also

[GetHeader Method](#)

MessageIndex Property

Gets and sets the current message number on the server.

Syntax

object.MessageIndex [= *value*]

Remarks

The **MessageIndex** property sets or returns the current message number on the server. Message numbers range from 1 through the number of messages available on the server, as returned by the **LastMessage** property. Setting the **MessageIndex** property to an invalid message number will generate an error.

Data Type

Integer (Int32)

See Also

[MessageCount Property](#), [MessageFlags Property](#), [MessageSize Property](#), [MessageUID Property](#)

MessagePart Property

Gets and sets the current part in a multipart message.

Syntax

object.MessagePart [= *part*]

Remarks

The **MessagePart** property returns the current message part index. All messages have at least one part, which consists of one or more header fields, followed by the body of the message. The default part, part 0, refers to the main message header and body. If the message contains multiple parts (as with a message that contains one or more attached files), the **MessagePart** property can be set to refer to that specific part of the message.

Messages with file attachments typically consist of a message part which describes the contents of the attachment, followed by the attachment itself. For a message with one attached file, there would be a total of three parts. Part 0 would refer to the main message part, which contains the headers such as From, To, Subject, Date and so on. For multipart messages, part 0 typically does not have a message body, since any text is usually created as a separate part (for those messages that do not contain multiple parts, the part 0 body contains the text message). Part 1 would contain the text describing the attachment, and part 2 would contain the attachment itself. If the attached file is binary, then the transfer encoding type would usually be base64.

Data Type

Integer (Int32)

See Also

[ContentType Property](#), [ContentLength Property](#), [Encoding Property](#), [MessageParts Property](#)

MessageParts Property

Return the number of parts in the current message.

Syntax

object.**MessageParts**

Remarks

The **MessageParts** property returns the number of parts in the current message. All messages have at least one part, referenced as part 0. Multipart messages will consist of additional parts which may be accessed by setting the **MessageParts** property.

Data Type

Integer (Int32)

See Also

[MessagePart Property](#), [AttachFile Method](#), [ExtractFile Method](#), [ExportMessage Method](#)

MessageSize Property

Return the size of the current message in bytes.

Syntax

object.MessageSize

Remarks

The **MessageSize** property returns the size of the current message in bytes. The size includes the header and body portion of the message.

Data Type

Integer (Int32)

See Also

[Message Property](#), [MessageCount Property](#)

MessageText Property

Return or change the text in the current message part.

Syntax

object.MessageText [= *value*]

Remarks

The **MessageText** property returns the body of the current message part. Setting this property replaces the entire message body with the new text. Note that setting the property to an empty string deletes the body of the current message part, but does not delete the message part itself.

Data Type

String

MessageUID Property

Return the UID for the current message on the mail server.

Syntax

object.MessageUID

Remarks

The **MessageUID** property returns a string which uniquely identifies the message on the server. The identifier is assigned by the mail server, and retains the same value across multiple client sessions. This value is typically used when the client wants to leave a message on the mail server, but does not wish to retrieve the message contents multiple times. For example, the client can store the UID for each message that it retrieves, but does not delete from the server. The next time that it connects to the mail server, it compares the UID of a message against the stored values. If there is a match, the client knows that the message has already been retrieved, and does not need to do so again.

This property requires that the mail server support the optional UIDL command. If the command is not supported, this property will always return an empty string. Note that the UID for the message comes from the mail server and is not the same as the Message-ID header field in the message itself.

Data Type

String

NameServer Property

Gets and sets the Internet address for a nameserver.

Syntax

object.NameServer(*index*) [= *value*]

Remarks

The **NameServer** property array is used to specify one or more nameservers. The address value must be an Internet address in dot notation. The ***index*** specifies which nameserver to set or return a value for. There may be up to four nameservers defined for any single instance of the object.

A nameserver is a computer which converts a domain name, such as microsoft.com, into an IP address which can be used to establish a connection to a server. In addition to mapping domain names, nameservers also can return information about what servers are responsible for handling mail messages for a given domain. These servers are called "mail exchanges" and there may be more than one mail exchange for a domain, each with its own assigned priority. This information is used by the **SendMessage** method to determine the address of the appropriate SMTP server in order to deliver the message to the specified recipient.

If no nameservers are specified, then the default nameservers for the local host will be used. For those systems which use dial-up connections to the Internet, this requires that the system have an active connection established before this object is initialized.

Data Type

String

NewMessages Property

Return the number of new messages available in the current mailbox.

Syntax

object.NewMessages

Remarks

The **NewMessages** property returns the number of new, unread messages available to be retrieved from the currently selected mailbox.

This property value is only meaningful when connected to an IMAP server. If the control is connected to a POP3 server, this property will always return the same value as the **MessageCount** property.

Data Type

Integer (Int32)

See Also

[MessageCount Property](#), [RecentMessages Property](#), [UnreadMessages Property](#), [CheckMailbox Method](#)

Organization Property

Return or change the name of the organization that created the message.

Syntax

object.**Organization** [= *name*]

Remarks

The **Organization** property returns the name of the organization that sent the current message. Setting this property updates the specified header value. Note that many mailers do not generate an Organization header field, in which case the property value will be an empty string.

Data Type

String

See Also

[GetHeader Method](#), [SetHeader Method](#)

Password Property

Gets and sets the password for the current user.

Syntax

object.Password [= *value*]

Remarks

The **Password** property specifies the password used to authenticate the user. If the property is not explicitly set, then an application must provide the password to the **Connect** method. Once the connection has been established, this property will be updated with the appropriate value.

If you have assigned a value to the **BearerToken** property, this property will return an empty string. If a value is assigned to this property, the **BearerToken** property will be cleared and standard password authentication will be used when connecting to the mail server.

Data Type

String

See Also

[BearerToken Property](#), [UserName Property](#), [Connect Method](#)

Priority Property

Gets and sets the current message priority.

Syntax

object.Priority [= *name*]

Remarks

The **Priority** property returns the current priority for the message. Setting this property value causes the X-Priority header to be updated with the specified value.

There is no strict standard for specifying message priority. The convention is to use a number from 1-5, with 1 indicating the highest priority, 3 as normal priority and 5 as the lowest priority. Some mailers follow the number with a space and then text that describes the priority level.

Data Type

String

See Also

[GetHeader Method](#), [SetHeader Method](#)

RecentMessages Property

Returns the number of messages which have recently arrived in the mailbox.

Syntax

object.RecentMessages

Remarks

The **RecentMessages** property returns the number of messages which have been recently added to the currently selected mailbox. This property is particularly useful when the INBOX mailbox is selected, since it enables the application to check if any new messages have arrived.

This property value is only meaningful when connected to an IMAP server. If the control is connected to a POP3 server, this property will always return the same value as the **MessageCount** property.

Data Type

Integer (Int32)

See Also

[Mailbox Property](#), [Mailboxes Property](#), [MailboxFlags Property](#), [MessageCount Property](#), [UnreadMessages Property](#)

Recipient Property

Return the address of a message recipient.

Syntax

object.Recipient(*index*)

Remarks

The **Recipient** property array returns the email address of one of the recipients of the current message, as specified by the *index* argument. This property enables an application to enumerate all of the recipient addresses for the current message without having to parse the individual **To**, **Cc** and **Bcc** property values. Note that this property array is read-only; to change the recipients for the current message you must set the **To**, **Cc** or **Bcc** properties.

The *index* argument specifies which address to return, with a base value of zero up to the number of recipients.

The string returned by the **Recipient** property contains only the actual email address and does not include the name of the recipient or any comments that may have been included with the address. For example, if the **To** property is set to "John Doe <jdoe@company.com>" then the **Recipient** property would return a value of "jdoe@company.com" for that address.

Data Type

String

Example

The following example enumerates all of the recipients for the current message and adds them to a listbox:

```
For nIndex = 0 To InternetMail1.Recipients
    List1.AddItem InternetMail1.Recipient(nIndex)
Next
```

See Also

[Bcc Property](#), [Cc Property](#), [Recipients Property](#), [To Property](#)

Recipients Property

Return the number of recipients for the current message.

Syntax

object.Recipients

Remarks

The **Recipients** property returns the number of recipients for the current message. This value can be used in conjunction with the **Recipient** property array to enumerate the recipient email addresses for the current message.

Example

The following example enumerates all of the recipients for the current message and adds them to a listbox:

```
For nIndex = 0 To InternetMail1.Recipients
    List1.AddItem InternetMail1.Recipient(nIndex)
Next
```

Data Type

Integer (Int32)

See Also

[Recipient Property](#)

RelayServer Property

Gets and sets the host name or address of a relay server.

Syntax

object.RelayServer [= *value*]

Remarks

The **RelayServer** property is used to specify an alternate mail server which will deliver messages for the current user.

Normally, when the **SendMessage** method is used, the recipient address is used to determine what mail server is responsible for accepting messages for that user. However, under some circumstances this may not be desirable or even possible. For example, many Internet Service Providers (ISPs) require that customers send all messages through their servers and block any attempt to establish a direct connection with another mail server. Setting the **RelayServer** property to the host name or address of the ISP mail server will cause all messages to be relayed through that server rather than directly to the recipient.

Note that using a mail server as a relay without the permission of the organization or individual who owns that server may violate Acceptable Use Policies and/or Terms of Service agreements with your service provider.

Data Type

String

See Also

[ServerName Property](#), [ServerPort Property](#), [RelayPort Property](#)

RelayPort Property

Gets and sets the port number for the specified relay server.

Syntax

object.RelayPort [= *value*]

Remarks

The **RelayPort** property defines the port number which is used to establish a connection with the mail server. This property is used in conjunction with the **RelayServer** property to specify an alternate mail server which is responsible for delivering messages for the current user.

If this property is not set, the default SMTP port will be used when connecting to a relay mail server.

Data Type

Integer (Int32)

See Also

[RelayServer Property](#)

ReplyTo Property

Gets and sets the address of the person who should receive replies to this message.

Syntax

object.ReplyTo [= *value*]

Remarks

The **ReplyTo** property returns the address of the user who should receive replies to the current message. Setting this property updates the Reply-To header field with the specified value.

Data Type

String

See Also

[Bcc Property](#), [Cc Property](#), [From Property](#), [To Property](#)

ReturnReceipt Property

Gets and sets the address of the person who should receive a message indicating that the message has been read.

Syntax

object.ReturnReceipt [= *value*]

Remarks

The **ReturnReceipt** property returns the address of the person who should receive a message indicating that the current message has been read. Setting this property updates the Disposition-Notification-To header field with the specified value.

Setting the **ReturnReceipt** property does not automatically cause an acknowledgement to be returned to the sender. An application is responsible for checking to make sure the header field contains a valid address and then generating the return receipt message.

Data Type

String

Secure Property

Specify if a connection to the server is secure.

Syntax

object.Secure [= { True | False }]

Remarks

The **Secure** property determines if a secure connection is established to the server. The default value for this property is False, which specifies that a standard connection to the server is used. To establish a secure connection, the application must set this property value to True prior to calling the **Connect** method. Once the connection has been established, the client may retrieve messages from the server as with standard connections.

It is strongly recommended that any application that sets this property to True use error handling to trap any errors that may occur. If the control is unable to initialize the security libraries, or otherwise cannot create a secure session for the client, an error will be generated when this property value is set.

Data Type

Boolean

Example

The following example establishes a secure connection to a server and retrieves a message:

```
InternetMail1.ServerType = mailServerPop3
InternetMail1.ServerName = strServerName
InternetMail1.UserName = strUserName
InternetMail1.Password = strPassword
InternetMail1.Secure = True

nError = InternetMail1.Connect()
If nError > 0 Then
    MsgBox "Unable to connect to server " & strServerName, vbExclamation
    Exit Sub
End If

If InternetMail1.CertificateStatus <> mailCertificateValid Then
    nResult = MsgBox("The server certificate could not be validated" & vbCrLf & _
        "Are you sure you wish to continue?", vbYesNo)

    If nResult = vbNo Then
        InternetMail1.Disconnect
        Exit Sub
    End If
End If

nError = InternetMail1.GetMessage(1)
If nError > 0 Then
    InternetMail1.Disconnect
    MsgBox "Unable to retrieve message from server " & strServerName
    Exit Sub
End If

InternetMail1.Disconnect
```

See Also

[CertificateExpires Property](#), [CertificateIssued Property](#), [CertificateIssuer Property](#), [CertificateStatus Property](#), [CertificateSubject Property](#), [CipherStrength Property](#), [HashStrength Property](#), [SecureCipher Property](#), [SecureHash Property](#), [SecureKeyExchange Property](#), [SecureProtocol Property](#), [Connect Method](#)

SecureCipher Property

Return the encryption algorithm used to establish the secure connection with the server.

Syntax

object.SecureCipher

Remarks

The **SecureCipher** property returns an integer value which identifies the algorithm used to encrypt the data stream. This property may return one of the following values:

Value	Description
stCipherNone	No cipher has been selected. This is not a secure connection with the server.
stCipherRC2	The RC2 block cipher was selected. This is a variable key length cipher which supports keys between 40- and 128-bits in length, in 8-bit increments.
stCipherRC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40- and 128-bits in length, in 8-bit increments.
stCipherRC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.
stCipherDES	The DES (Data Encryption Standard) block cipher was selected. This is a fixed key length cipher using 56-bit keys.
stCipherDES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively using a 168-bit key length.
stCipherDESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.
stCipherAES	The Advanced Encryption Standard cipher (also known as the Rijndael cipher) is a fixed block size cipher which use a key size of 128, 192 or 256 bits. This cipher is supported on Windows XP SP3 and later versions of the operating system.
stCipherSkipjack	The Skipjack block cipher was selected. This is a fixed key length cipher, using 80-bit keys.
stCipherBlowfish	The Blowfish block cipher was selected. This is a variable key length cipher up to 448 bits, using a 64-bit block size.

If a secure connection has not been established, this property will return a value of zero.

Data Type

Integer (Int32)

See Also

[CipherStrength Property](#), [HashStrength Property](#), [Secure Property](#), [SecureHash Property](#), [SecureKeyExchange Property](#), [SecureProtocol Property](#)

SecureHash Property

Return the message digest selected when establishing the secure connection with the server.

Syntax

object.SecureHash

Remarks

The **SecureHash** property returns an integer value which identifies the message digest algorithm that was selected when a secure connection is established. This property may return one of the following values:

Value	Description
mailHashMD5	The MD5 algorithm was selected. This algorithm has been deprecated and is no longer considered to be cryptographically secure.
mailHashSHA1	The SHA-1 algorithm was selected. This algorithm has been deprecated and is no longer considered to be cryptographically secure.
mailHashSHA256	The SHA-256 algorithm has been selected.
mailHashSHA384	The SHA-384 algorithm has been selected.
mailHashSHA512	The SHA-512 algorithm has been selected.

If a secure connection has not been established, this property will return a value of zero.

Data Type

Integer (Int32)

See Also

[CipherStrength Property](#), [HashStrength Property](#), [Secure Property](#), [SecureCipher Property](#), [SecureKeyExchange Property](#), [SecureProtocol Property](#)

SecureKeyExchange Property

Return the key exchange algorithm used to establish the secure connection with the server.

Syntax

object.SecureKeyExchange

Remarks

The **SecureKeyExchange** property returns an integer value which identifies the key-exchange algorithm used when establishing a secure connection. This property may return one of the following values:

Value	Description
stKeyExchangeNone	No key exchange algorithm has been selected. This is not a secure connection with the server.
stKeyExchangeRSA	The RSA public key exchange algorithm has been selected.
stKeyExchangeKEA	The KEA public key exchange algorithm has been selected. This is an improved version of the Diffie-Hellman public key algorithm.
stKeyExchangeDH	The Diffie-Hellman public key exchange algorithm has been selected.
stKeyExchangeECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography. This key exchange algorithm is only supported on Windows XP SP3 and later versions of the operating system.

If a secure connection has not been established, this property will return a value of zero.

Data Type

Integer (Int32)

See Also

[CipherStrength Property](#), [HashStrength Property](#), [Secure Property](#), [SecureCipher Property](#), [SecureHash Property](#), [SecureProtocol Property](#)

SecureProtocol Property

Gets and sets the security protocol used to establish the secure connection with the server.

Syntax

object.SecureProtocol [= *protocol*]

Remarks

The **SecureProtocol** property can be used to specify the security protocol to be used when establishing a secure connection with a server. By default, the control will attempt to use TLS 1.3 to establish the connection. If TLS 1.3 is not supported, TLS 1.2 will be used. The appropriate protocol is automatically selected based on the capabilities of both the client and server.

It is recommended that you only change this property value if you fully understand the implications of doing so. Assigning a value to this property will override the default and force the control to attempt to use only the protocol specified. One or more of the following values may be used:

Value	Description
stProtocolNone	No security protocol has been selected. A secure connection has not been established.
stProtocolTLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
stProtocolTLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
stProtocolTLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
stProtocolTLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

Multiple security protocols may be specified by combining them using a bitwise Or operator. After a connection has been established, reading this property will identify the protocol that was selected to establish the connection. Attempting to set this property after a connection has been established will result in an exception being thrown. This property should only be set after setting the **Secure** property to True and before calling the **Connect** method.

Data Type

Integer (Int32)

See Also

[CipherStrength Property](#), [HashStrength Property](#), [Secure Property](#), [SecureCipher Property](#), [SecureHash Property](#), [SecureKeyExchange Property](#)

ServerName Property

Gets and sets the host name of the current mail server.

Syntax

object.ServerName [= *value*]

Remarks

The **ServerName** property returns the name of the mail server that the client is connected to. Setting this property specifies the host name or Internet address for a subsequent connection.

If the **ServerName** property is not explicitly set, then an application must provide the host name or address to the **Connect** method. Once the connection has been established, this property will be updated with the appropriate value. If the server uses a non-standard port number, it can be specified using the **ServerPort** property.

The mail server must support Post Office Protocol v3 (POP3) to retrieve messages. Setting this property does not affect what server is used to deliver messages. See the **RelayServer** and **RelayPort** properties to specify a mail server that is responsible for relaying messages.

Data Type

String

See Also

[RelayPort Property](#), [RelayServer Property](#), [ServerPort Property](#), [ServerType Property](#), [Connect Method](#)

ServerPort Property

Gets and sets the port number for the current mail server.

Syntax

object.ServerPort [= *value*]

Remarks

The **ServerPort** property returns the port number that was used to establish a connection with the mail server. Setting this property specifies an alternate port number to use for a subsequent connection. A value of zero specifies that the default port should be used for the connection.

The mail server must support Post Office Protocol v3 (POP3) to retrieve messages. Setting this property does not affect what server is used to deliver messages. See the **RelayServer** and **RelayPort** properties to specify a mail server that is responsible for relaying messages.

Data Type

Integer (Int32)

See Also

[RelayPort Property](#), [RelayServer Property](#), [ServerName Property](#), [ServerType Property](#), [Connect Method](#)

ServerType Property

Gets and sets the type of mail server the client is connecting to.

Syntax

object.ServerType [= *servertype*]

Remarks

The **ServerType** property may be used to specify the mail server type before establishing a connection. If this property is not explicitly set in code, then the control will attempt to automatically determine which protocol should be used based on the value of the **ServerPort** property. By default, the control will attempt to use the POP3 protocol.

This property may return one of the following values:

Value	Description
mailServerDefault	The default server type is determined by the value of the ServerPort property. If that property has not been set, then the control will use the Post Office Protocol (POP3) as the default protocol when establishing the connection.
mailServerPop3	The mail server is using the Post Office Protocol (POP3)
mailServerImap4	The mail server is using the Internet Message Access Protocol (IMAP4)

It is important to note that certain properties and methods in the control are specific to the IMAP4 protocol, such as those that are used to select and enumerate mailboxes. If you are unsure which protocol your mail server supports, contact the system administrator.

Data Type

Integer (Int32)

See Also

[Secure Property](#), [ServerName Property](#), [ServerPort Property](#), [Connect Method](#)

Subject Property

Gets and sets the subject of the current message.

Syntax

object.Subject [= *value*]

Remarks

The **Subject** property returns the subject of the current message. Setting this property updates the Subject header with the specified value. Note that not all messages have subjects, in which case this property will return an empty string.

Data Type

String

See Also

[GetHeader Method](#), [SetHeader Method](#)

ThrowError Property

Enables or disables error handling by the application.

Syntax

object.ThrowError [= { True | False }]

Remarks

Error handling for methods can be performed using either return codes or exceptions, depending on the value of this property.

If the **ThrowError** property is set to False, methods will return a status value indicating success or failure. Applications should check the return value of each method and use the **LastError** and **LastErrorString** properties to determine the cause of any error.

If the **ThrowError** property is set to True, errors occurring within the control will be raised to the host application as ActiveX exceptions. In addition, the **OnError** event will fire. This allows applications to use language-specific exception handling mechanisms, such as Visual Basic error handling, instead of checking individual return values after each method call.

Even when the **ThrowError** property is set to True, the **LastError** and **LastErrorString** properties will still be updated with information about the most recent error.

If an error occurs while accessing a property value, an exception will be raised regardless of the value of the **ThrowError** property. However, the **OnError** event will not be fired for property access errors.

Data Type

Boolean

See Also

[LastError Property](#), [OnError Event](#)

Timeout Property

Gets and sets the amount of time until a blocking network operation is aborted.

Syntax

object.Timeout [= *value*]

Remarks

The **Timeout** property controls the amount of time that the component will wait for a network operation to complete before aborting the operation and returning an error. The default value for this property is 20 seconds. It may be required to increase this value if a slow or unreliable network connection is being used.

Data Type

Integer (Int32)

See Also

[Connect Method](#), [SendMessage Method](#)

TimeZone Property

Gets and sets the current timezone offset in seconds.

Syntax

object.TimeZone [= *value*]

Remarks

The **TimeZone** property returns the current offset from UTC in seconds. Setting the property changes the current timezone offset to the specified value. The value of this property is initially determined by the date and time settings on the local system.

The **TimeZone** property value is used in conjunction with the **Localize** property to control how message date and time localization is handled.

Data Type

Integer (Int32)

Example

The following code enables localization and changes the current timezone to Eastern Standard, which is five hours (18,000 seconds) west of UTC:

```
InternetMail1.Localize = True  
InternetMail1.TimeZone = (5 * 60 * 60)
```

See Also

[Localize Property](#)

To Property

Gets and sets the recipient of the current message.

Syntax

object.To [= *value*]

Remarks

The **To** property returns the list of addresses that received a copy of the current message. If there is no current message, or the To header field is not defined, then this property will return an empty string.

Setting the **To** property creates or changes the value of the To header field in the message and specifies additional recipients of the message. Multiple addresses may be specified by separating them with a comma. Each address must conform to the standard Internet address format.

Data Type

String

See Also

[Bcc Property](#), [Cc Property](#), [From Property](#), [ReplyTo Property](#)

Trace Property

Enable or disable network function level logging.

Syntax

`object.Trace [= { True | False } ]`

Remarks

The **Trace** property is used to enable or disable the logging of network function calls. When enabled, each function call is logged to a file, including the function parameters, return value and error code if applicable. This facility can be enabled and disabled at run time, and the trace log file can be specified by setting the **TraceFile** property. All function calls that are being logged are appended to the trace file, if it exists. If no log file exists when tracing is enabled, the file is created.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

Data Type

Boolean

See Also

[TraceFile Property](#), [TraceFlags Property](#)

TraceFile Property

Gets and sets the name of the file to use when logging network function calls.

Syntax

`object.TraceFile [= filename ]`

Remarks

The **TraceFile** property is used to specify the name of the file that is created when logging is enabled. If this property is set to an empty string (the default value), then a file named **SocketTools.log** is created in the current user's Documents folder. It is recommended that you always specify a complete path to the log file. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

If the file exists, the output is appended to the file, otherwise the file is created. Since logging is enabled per-process, the log file is shared by all instances of the controls being used. If you create multiple instances of the control, you only need to enable logging for a single instance. Because log files can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "0x". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxx:xxxx:xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, the control is attempting to connect to a system with the IPv4 address 192.0.0.1 on port 1234.

If the log file cannot be created, or the user does not have permission to modify an existing file, the error is silently ignored and no output will be generated.

Data Type

String

See Also

TraceFlags Property

Gets and sets the network function logging flags.

Syntax

`object.TraceFlags [= flags ]`

Remarks

The **TraceFlags** property is used to specify the type of information written to the trace file when socket function tracing is enabled. The following values may be used:

Value	Description
dnsTraceInfo	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
dnsTraceError	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
dnsTraceWarning	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
dnsTraceHexDump	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
dnsTraceTruncate	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.

Since logging is enabled per-process, the trace flags are shared by all instances of the control being used. If multiple controls have tracing enabled, the **TraceFlags** property should be set to the same value for each control. Changing the trace flags for any one instance of the control will affect the logging performed for all other instances used by the application.

Warnings are generated when a non-fatal error is returned by a Windows Sockets function. For example, if data is being written through the control and an error indicating that the operation would block is returned, only a warning is logged since the application simply needs to attempt to write the data at a later time.

Data Type

Integer (Int32)

See Also

[Trace Property](#), [TraceFile Property](#)

UnreadMessages Property

Returns the number of unread messages in the current mailbox.

Syntax

object.UnreadMessages

Remarks

The **UnreadMessages** property returns the number of messages which do not have the SEEN flag in the current mailbox. This value is not the same as the number of recent messages in a mailbox, which is based on when the message was stored in the mailbox. To obtain a list of messages that have not been read, use the **SearchMailbox** method with UNSEEN as the search criteria.

It is possible that a message may be flagged as seen if it has been previously accessed by a different mail client. For example, a client may retrieve a message from an INBOX mailbox using the POP3 protocol, which would cause that message to be flagged as seen. This behavior is server dependent, and is most commonly found where the mail server supports both the POP3 and IMAP4 protocols.

Data Type

Integer (Int32)

See Also

[MessageCount Property](#), [NewMessages Property](#), [RecentMessages Property](#), [SearchMailbox Method](#)

UserName Property

Gets and sets the current user name.

Syntax

object.UserName [= *value*]

Remarks

The **UserName** property specifies the name used to authenticate the user. If the property is not explicitly set, then an application must provide the user name to the **Connect** method. Once the connection has been established, this property will be updated with the appropriate value.

Data Type

String

See Also

[BearerToken Property](#), [Password Property](#), [Connect Method](#)

Version Property

Return the current version of the control.

Syntax

object.**Version**

Remarks

The **Version** property returns the current version of the object. This can be used by an application for validation purposes.

Data Type

String

Internet Mail Control Methods

Method	Description
AppendMessage	Append text to the current message part
AttachData	Attach the contents of a buffer to the current message
AttachFile	Attach the specified file to the current message
AttachImage	Attach an inline image to the current message
Cancel	Cancel the current operation
ChangePassword	Change the mailbox password for the specified user
CheckMailbox	Create a checkpoint of the currently selected mailbox
ComposeMessage	Compose a new mail message
Connect	Establish a connection with the specified mail server
ClearMessage	Clear the current message
CopyMessage	Copy a message from the current mailbox to another mailbox
CreateMailbox	Creates a new mailbox on the server
CreateMessage	Create a new message
CreatePart	Create a new message part in a multipart message
DeleteHeader	Delete a header field from the current message part
DeleteMailbox	Deletes a mailbox from the server
DeleteMessage	Delete the specified message from the mail server
DeletePart	Delete the specified message part in the current message
Disconnect	Disconnect from the mail server
ExportMessage	Export the current message to a text file
ExtractAllFiles	Extract all file attachments from the current message
ExtractFile	Extract an attached file from the current message
FindAttachment	Search the current message for a file attachment with the specified file name
GetFirstHeader	Return the first header in the current message part
GetHeader	Return the value for the specified header in the current message part
GetNextHeader	Return the next header in the current message part
GetMessage	Retrieve the specified message from the mail server
Idle	Enables mailbox status monitoring for the client session
ImportMessage	Import a new message from the specified text file
Initialize	Initialize the component and load the networking library
ParseAddress	Parse an Internet email address

ParseMessage	Parse the specified string, adding the contents to the current message
Reset	Reset the state of the component
RenameMailbox	Change the name of a mailbox
SearchMailbox	Search the current mailbox for messages that match the specified criteria
SelectMailbox	Selects the specified mailbox for read-write access
SendMessage	Send an email message to one or more recipients
SetHeader	Set the value of a header field in the current message part
StoreMessage	Store the specified message in a file
UndeleteMessage	Removes the deletion flag for the specified message
Uninitialize	Uninitialize the component and unload the networking library
UnselectMailbox	Unselects the current mailbox

AppendMessage Method

Append text to the current message part.

Syntax

object.AppendMessage(*MessageText*)

Parameters

MessageText

A string which specifies the text to append.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **AppendMessage** method appends the specified string to the end of the body of text in the current message part. Each line of text contained in the string should be terminated with a carriage-return/linefeed (CRLF) pair, which is recognized as the end-of-line.

See Also

[MessagePart Property](#), [ComposeMessage Method](#), [CreatePart Method](#)

AttachData Method

Attach the contents of a buffer to the current message.

Syntax

object.AttachData(Buffer, [Length], [ContentName], [ContentType], [Options])

Parameters

Buffer

A string or byte array which specifies the data to be attached to the message. If an empty string is passed as the argument, no data is attached, but an additional empty message part will be created.

Length

An integer value which specifies the number of bytes of data in the buffer. If this value is omitted, the entire length of the string or size of the byte array is used.

ContentName

An optional string argument which specifies a name for the data being attached to the message. This typically is used as a file name by the mail client to store the data in. If this parameter is omitted or passed as an empty string then no name is defined and the data is attached as inline content. Note that if a file name is specified with a path, only the base name will be used.

ContentType

An optional string argument which specifies the type of data being attached. The value must be a valid MIME content type. If this parameter is omitted or passed as an empty string, then the buffer will be examined to determine what kind of data it contains. If there is only text characters, then the content type will be specified as "text/plain". If the buffer contains binary data, then the content type will be specified as "application/octet-stream", which is appropriate for any type of data.

Options

An optional integer value which specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
mailAttachDefault	The data encoding is based on the content type. Text data is not encoded, and binary data is encoded using the standard base64 encoding algorithm. If this argument is omitted, this is the default value used.
mailAttachBase64	The data is always encoded using the standard base64 algorithm, even if the buffer only contains printable text characters.
mailAttachUucode	The data is always encoded using the uuencode algorithm, even if the buffer only contains printable text characters.
mailAttachQuoted	The data is always encoded using the quoted-printable algorithm. This encoding should only be used if the data contains 8-bit text characters.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **AttachData** method attaches the contents of a string or byte buffer to the current message.

Example

The following example demonstrates how to use the **AttachData** method in Visual Basic:

```
Dim hFile As Integer
Dim lpBuffer() As Byte
Dim cbBuffer As Long

' Open a file for binary access and read it into a
' byte array that will be attached to the message

hFile = FreeFile()
Open strDataFile For Binary As hFile
cbBuffer = LOF(hFile)
ReDim lpBuffer(cbBuffer)
Get hFile, , lpBuffer
Close hFile

' Compose a new message and then attach the contents
' of the buffer

InternetMail1.ComposeMessage strFrom, _
                             strTo, _
                             strCc, _
                             strSubject, _
                             strMessage

InternetMail1.AttachData lpBuffer, cbBuffer, strDataFile
```

See Also

[Attachment Property](#), [AttachFile Method](#), [ExtractFile Method](#)

AttachFile Method

Attach the specified file to the current message.

Syntax

object.AttachFile(*FileName*, [*Options*])

Parameters

FileName

A string that specifies the name of the file to be attached to the message. If the string is empty or the file does not exist, an error will be returned.

Options

An integer value that specifies the type of encoding that will be applied to the attachment. If this argument is not specified, then text files will not be encoded and binary files will be encoded using the standard base64 algorithm.

Value	Description
mailAttachDefault	The file attachment encoding is based on the file content type. Text files are not encoded, and binary files are encoded using the standard base64 algorithm. This is the default option for file attachments.
mailAttachBase64	The file attachment is always encoded using the standard base64 algorithm, even if the attached file is a plain text file.
mailAttachUucode	The file attachment is always encoded using the standard uuencode algorithm, even if the attached file is a plain text file.
mailAttachQuoted	The file attachment is always encoded using quoted-printable encoding. Note that this encoding method is only recommended for text content, typically either as HTML or RTF.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **AttachFile** method attaches the specified file to the current message. If the message already contains one or more file attachments, then it is added to the end of the message. If the message does not contain any attached files, then it is converted to a multipart message and the file is appended to the message.

See Also

[ContentType Property](#), [AttachData Method](#), [ExtractFile Method](#)

AttachImage Method

Attach an inline image to the current message.

Syntax

object.AttachImage(*FileName*, [*ContentId*])

Parameters

FileName

A string that specifies the name of the file that contains the image which should be attached to the message. If the string is empty or the file does not exist, an error will be returned.

ContentId

An optional string value which specifies the content ID that is associated with the inline image. If this parameter is omitted or is an empty string, a random content ID string will be automatically generated.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **AttachImage** method attaches an inline image to the current message. Unlike a normal file attachment, this method is designed to be used with HTML formatted email messages that display images attached to the message. If the message already contains one or more images or file attachments, then it is added to the end of the message. If the message does not contain any attachments, then it is converted to a multipart message and the image is appended to the message. To attach regular files to the message, use the **AttachFile** method.

See Also

[ContentType Property](#), [AttachData Method](#), [ExtractFile Method](#)

Cancel Method

Cancel the current blocking network operation.

Syntax

object.Cancel

Parameters

None.

Return Value

None.

Remarks

The **Cancel** method cancels any blocking network operation in the current thread. This is typically used inside an event handler, causing the blocking method to return to the caller with an error indicating that the current operation was canceled. This method sets an internal flag that is periodically checked during a blocking operation, such as waiting for more data to arrive. If the current thread is not blocked at the time that this method is called, it will have no effect.

See Also

[Reset Method](#), [OnCancel Event](#)

ChangePassword Method

Change the mailbox password for the specified user.

Syntax

*object.ChangePassword(**UserName**, **OldPassword**, **NewPassword**)*

Parameters

UserName

A string that specifies the username for the mailbox.

OldPassword

A string that specifies the current password for the user's mailbox. An error will be returned if this is an empty string.

NewPassword

A string that specifies the new password for the user's mailbox. An error will be returned if this is an empty string, or if the old and new password are the same value.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

The **ChangePassword** method changes the password that will be used to authenticate the specified user. If the **UserName** parameter is the same value as the **UserName** property, then successfully changing the password will cause the **Password** property to be updated with the new password

Note that in order to change the user's mailbox password, the server must be running the poppass service on port 106, on the same server. Because passwords are transmitted as clear text (unencrypted), this service is not considered secure and may not be available.

See Also

[Password Property](#), [UserName Property](#)

CheckMailbox Method

Create a checkpoint of the currently selected mailbox.

Syntax

object.CheckMailbox

Parameters

None.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **CheckMailbox** method requests that the server create a checkpoint of the currently selected mailbox, and updates the current number of new, unread messages available to the client.

When the client requests a checkpoint, the server may perform implementation-dependent housekeeping for that mailbox, such as updating the mailbox on disk with the current state of the mailbox in memory. On some systems this command has no effect other than to update the client with the current number of messages in the mailbox.

This function actually sends two IMAP commands. The first is the CHECK command, followed by the NOOP command to poll for any new messages that have arrived. In addition to polling the server for new messages, this command can also be used to ensure the idle timer on the server does not expire and force a disconnect from the client.

This method can only be used when connected to an IMAP server.

[MailboxName Property](#), [MessageCount Property](#), [NewMessages Property](#), [RecentMessages Property](#)

ComposeMessage Method

Compose a new mail message.

Syntax

```
object.ComposeMessage( From, To, [Cc], [Bcc], [Subject], [MessageText], [MessageHTML],  
[CharacterSet], [EncodingType] )
```

Parameters

From

A string that specifies the sender's email address. Only a single address should be used. After the message has been composed, the **From** property will be updated with this value.

To

A string that specifies one or more recipient email addresses. Multiple email addresses may be specified by separating them with commas. After the message has been composed, the **To** property will be updated with this value.

Cc

An optional string that specifies one or more additional recipient addresses that will receive a copy of the message. If this argument is not specified, then no Cc header field will be created for this message. After the message has been composed, the **Cc** property will be updated with this value.

Bcc

An optional string that specifies one or more additional recipient addresses that will receive a copy of the message. Unlike the **cc** argument, these recipients will not be included in the header of the message. If this argument is not specified, then no blind carbon copies of the message will be sent. After the message has been composed, the **Bcc** property will be updated with this value.

Subject

An optional string that specifies the subject for the message. If the argument is not specified, then no Subject header field will be created for this message. After the message has been composed, the **Subject** property will be updated with this value.

MessageText

An optional string that contains the body of the message. Each line of text contained in the string should be terminated with a carriage-return/linefeed (CRLF) pair, which is recognized as the end-of-line. If this parameter is not specified, then the message will have an empty body unless the **MessageHTML** parameter has been specified.

MessageHTML

An optional string that contains an alternate HTML formatted message. If the **MessageText** parameter has been specified, then a multipart message will be created with both plain text and HTML text as the alternative. This allows mail clients to select which message body they wish to display. If the **MessageText** parameter is not specified or is an empty string, then the message will only contain HTML. Although this is supported, it is not recommended because older mail clients may be unable to display the message correctly.

CharacterSet

An optional integer value which specifies the [character set](#) for the message text. If this parameter is omitted, the default is for the message to be composed using the standard UTF-8 character set.

EncodingType

An optional integer value which specifies the default encoding for the message. If this parameter is omitted, the message will use standard 8-bit encoding. This parameter may be one of the following values:

Value	Description
mailEncoding7Bit	Each character is encoded in one or more bytes, with each byte being 8 bits long, with the first bit cleared. This encoding is most commonly used with plain text using the US-ASCII character set, where each character is represented by a single byte in the range of 20h to 7Eh.
mailEncoding8Bit	Each character is encoded in one or more bytes, with each byte being 8 bits long and all bits are used. 8-bit encoding is used with UTF-8 and other multi-byte character sets.
mailEncodingBinary	Binary encoding is essentially the absence of any encoding performed on the message data, and there is no presumption that the data contains textual information. No character set localization or conversion is performed on binary encoded data. This encoding type is not recommended. Instead, binary data should be encoded using the standard base64 algorithm.
mailEncodingQuoted	Quoted-printable encoding is designed for textual messages where most of the characters are represented by the ASCII character set and is generally human-readable. Non-printable characters or 8-bit characters with the high bit set are encoded as hexadecimal values and represented as 7-bit text. Quoted-printable encoding is typically used for messages which use character sets such as ISO-8859-1, as well as those which use HTML.
mailEncodingBase64	Base64 encoding is designed to represent binary data in a form that is not human readable but which can be safely exchanged with servers that only accept 7-bit data. Base64 encoding is typically used with file attachments.
mailEncodingUucode	Uuencoding and uudecoding is a legacy encoding format that was used before the MIME standard was established. This encoding method has largely been replaced by base64 encoding, although it is still commonly used for binary newsgroup postings on USENET. Although this encoding format is supported, it is not officially part of the MIME standard and its use in email messages is discouraged.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **ComposeMessage** method will replace the current message if one already exists.

Example

The following example composes a message and sends it to the specified recipients:

```
Dim nError As Long
```

```
nError = InternetMail1.ComposeMessage(comboFrom.Text, _  
                                     editTo.Text, _  
                                     editCc.Text, _  
                                     editBcc.Text, _  
                                     editSubject.Text, _  
                                     editMessage.Text)  
  
If nError > 0 Then  
    MessageBox "Unable to compose message", vbExclamation  
    Exit Sub  
End If  
  
nError = InternetMail1.SendMessage()  
  
If nError > 0 Then  
    MsgBox "Unable to send message", vbExclamation  
    Exit Sub  
End If
```

See Also

[Bcc Property](#), [Cc Property](#), [Encoding Property](#), [From Property](#), [MessageText Property](#), [Subject Property](#), [To Property](#)

Connect Method

Establish a connection with the specified mail server.

Syntax

```
object.Connect( [ServerName], [ServerPort], [Username], [Password], [Timeout], [Options] )
```

Parameters

ServerName

A string which specifies the host name or IP address of the mail server.

ServerPort

A number which specifies the port number used to connect to the server. If this argument is not specified, the value of the **ServerType** property will determine the default port number.

Username

A string which specifies the name of the user used to authenticate access to the server. If this argument is not specified, it defaults to the value of the **UserName** property.

Password

A string which specifies the password used to authenticate the user. If this argument is not specified, it defaults to the value of the **Password** property. If the **BearerToken** property has been assigned a value, this parameter will be ignored and OAuth 2.0 authentication will be used instead of standard password authentication.

Timeout

The number of seconds that the client will wait for a response before failing the operation. If this argument is not specified, the value of the **Timeout** property will be used as the default.

Options

A numeric value which specifies one or more options. If this argument is omitted or a value of zero is specified, a default, standard connection will be established. This argument is constructed by using a bitwise operator with any of the following values:

The settings for *Options* are:

Value	Description
mailOptionSecureImplicit	This option specifies that an implicit TLS session should be established with the mail server and prevents the use of a command which is used to negotiate an explicit TLS connection. This option should only be used if it is required.
mailOptionAPOP	Causes the APOP authentication method to be used when connecting to a POP3 mail server. The default is to use standard password authentication.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **Connect** method is used to establish a connection with the specified mail server. This is the first

method that must be called prior to the application retrieving mail messages using the **GetMessage** method. If this method is called when a connection already exists, the current connection will be closed. This has the side-effect of causing any messages which have been marked for deletion to be removed by the mail server.

If the **ServerType** property has not been explicitly set by the application, and a standard port number is specified, then the server type is automatically determined based on the value of the **ServerPort** parameter. If a non-standard port number is specified, then you must set the **ServerType** property to identify whether you are attempting to connect to a POP3 or IMAP4 server.

You should not call the **Connect** method when sending messages using SMTP. This method is only used to establish a connection with a POP3 or IMAP4 server. For more information about sending messages, see the **SendMessage** method and the **RelayServer** and **RelayPort** properties.

Example

The following example connects to a mail server and retrieves each of the mail messages, storing them in a file on the local system:

```
Dim strFileName As String
Dim nMessage As Long, nError As Long

nError = InternetMail1.Connect(strServerName, , strUserName, strPassword)

If nError > 0 Then
    MsgBox "Unable to connect to " & strServerName & vbCrLf & _
        InternetMail1.LastErrorString, vbExclamation
    Exit Sub
End If

If InternetMail1.LastMessage = 0 Then
    MsgBox "The mailbox is currently empty", vbInformation
    InternetMail1.Disconnect
    Exit Sub
End If

For nMessage = 1 To InternetMail1.LastMessage
    strFileName = "c:\temp\msg" & Format(nMessage, "0000") & ".txt"
    nError = InternetMail1.StoreMessage(nMessage, strFileName)
    If nError > 0 Then
        MsgBox "Unable to store message " & nMessage & vbCrLf & _
            InternetMail1.LastErrorString, vbExclamation
        Exit For
    End If
Next

If nError = 0 Then
    MsgBox "Stored " & InternetMail1.LastMessage & " messages", vbInformation
End If

InternetMail1.Disconnect
```

See Also

CopyMessage Method

Copy a message from the current mailbox to another mailbox.

Syntax

object.CopyMessage(*MessageNumber*, *MailboxName*, [*Options*])

Parameters

MessageNumber

The message identifier which specifies which message is to be copied to the mailbox. This value must be greater than zero and specify a valid message number.

MailboxName

A string which specifies the name of the mailbox that the message will be copied to. The mailbox must already exist, and the client must have the appropriate access rights to modify the mailbox.

Options

An optional parameter reserved for future use. This argument should either be omitted, or always be zero.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **CopyMessage** method copies a message from the current mailbox to the specified mailbox. The message is appended to the mailbox, and the message flags and internal date are preserved. If the mailbox does not exist, the function will fail. To create a new mailbox, use the **CreateMailbox** method. A message can be copied within the same mailbox, in which case the server may flag it as a new message.

See Also

[CreateMailbox Method](#), [CreateMessage Method](#), [GetMessage Method](#)

ClearMessage Method

Clear the current message.

Syntax

object.ClearMessage

Parameters

None.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **ClearMessage** method clears the current message, releasing the memory allocated for the message and any attachments. This will also reset the value of the **Bcc** property back to an empty string.

See Also

[ComposeMessage Method](#)

CreateMailbox Method

Creates a new mailbox on the server.

Syntax

object.CreateMailbox(*MailboxName*)

Parameters

MailboxName

A string which specifies the name of the new mailbox to be created.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **CreateMailbox** method creates a new mailbox on the server. If the mailbox name is suffixed with the server's hierarchy delimiter, this indicates to the server that the client intends to create mailbox names under the specified name in the hierarchy. If superior hierarchical names are specified in the mailbox name, then the server may automatically create them as needed. For example, if the mailbox name "Mail/Office/Projects" is specified and "Mail/Office" does not exist, it may be automatically created by the server.

The special mailbox name INBOX is reserved, and cannot be created. It is recommended that mailbox names only consist of printable ASCII characters, and the special characters "*" and "%" should be avoided.

See Also

[CheckMailbox Method](#), [DeleteMailbox Method](#), [SelectMailbox Method](#)

CreateMessage Method

Create a new message.

Syntax

`object.CreateMessage( MessageData, [MessageFlags], [MailboxName] )`

Parameters

MessageData

The contents of the message to be created. This may either be specified as a string or as an array of bytes.

MessageFlags

An optional integer value which specifies one or more message flags. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
mailFlagNone	No value.
mailFlagAnswered	The message has been answered.
mailFlagDraft	The message is not completed and is marked as a draft copy.
mailFlagUrgent	The message is flagged for urgent or special attention.
mailFlagSeen	The message has been read.

MailboxName

An optional string argument which specifies the name of the mailbox that the message will be created in. If this argument is omitted, the message will be created in the currently selected mailbox.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **CreateMessage** method creates a new message, appending it to the contents of the specified mailbox. This method will cause the current thread to block until the message transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

See Also

[GetMessage Method](#), [OnProgress Event](#)

CreatePart Method

Create a new message part in a multipart message.

Syntax

object.CreatePart([*MessageText*], [*CharacterSet*], [*EncodingType*])

Parameters

MessageText

An optional string that specifies the body of the new message part. Each line of text contained in the string should be terminated with a carriage-return/linefeed (CRLF) pair, which is recognized as the end-of-line. If the parameter is not specified, then the message part will have an empty body.

CharacterSet

An optional integer value that specifies the character set that will be used for this message part. If this parameter is omitted, the message part will use the standard UTF-8 character set. This parameter may be one of the following values:

Value	Description
mailCharsetUSASCII	A character set using US-ASCII which defines 7-bit printable characters with values ranging from 20h to 7Eh. An application that uses this character set has the broadest compatibility with most mail servers (MTAs) because it does not require the server to handle 8-bit characters correctly when the message is delivered. This is the most commonly used character set for plain text email messages in the English language.
mailCharsetISO8859_1	An 8-bit character set for most western European languages such as English, French, Spanish and German. This character set is also commonly referred to as Latin1. The Windows code page for this character set is 28591, however Windows code page 1252 (Windows-1252) is typically used to represent this character set in most applications.
mailCharsetISO8859_2	An 8-bit character set for most central and eastern European languages such as Czech, Hungarian, Polish and Romanian. This character set is also commonly referred to as Latin2. This character set is similar to Windows code page 1250, however the characters are arranged differently.
mailCharsetISO8859_5	An 8-bit character set for Cyrillic languages such as Russian, Bulgarian and Serbian. The Windows code page for this character set is 28595. This character set is not widely used and it is recommended that you use UTF-8 instead.
mailCharsetISO8859_6	An 8-bit character set for Arabic languages. Note that the application is responsible for displaying text that uses this character set. In particular, any display engine needs to be able to handle the reverse writing direction and analyze the context of the message to correctly combine the glyphs. This character set is not widely used and it is recommended that you use UTF-8 instead.

mailCharsetISO8859_7	An 8-bit character set for the Greek language. This character set is also commonly referred to as Latin/Greek. The Windows code page for this character set is 28597.
mailCharsetISO8859_8	An 8-bit character set for the Hebrew language. Note that similar to Arabic, Hebrew uses a reverse writing direction. An application which displays this character should be capable of processing bi-directional text where a single message may include both right-to-left and left-to-right languages, such as Hebrew and English. The Windows code page for this character set is 28598.
mailCharsetISO8859_9	An 8-bit character set for the Turkish language. This character set is also commonly referred to as Latin5. The Windows code page for this character set is 28599.
mailCharsetUTF7	A 7-bit Unicode Transformation Format that uses variable-length character encoding to represent Unicode text as a stream of ASCII characters that are safe to transport between mail servers that only support 7-bit printable characters. It is primarily used as an alternative to UTF-8 which requires that the mail server support 8-bit text or use quoted-printable encoding.
mailCharsetUTF8	An 8-bit Unicode Transformation Format that uses multi-byte character sequences to represent Unicode text. It is backwards compatible with the ASCII character set, however because it uses 8-bit text, it should be encoded using either quoted-printable or base64 encoding to ensure that mail servers that do not support 8-bit characters.

EncodingType

An optional integer value which specifies the encoding for this message part. If this parameter is omitted, the message part will use standard 7-bit encoding. This parameter may be one of the following values:

Value	Description
mailEncoding7Bit	Each character is encoded in one or more bytes, with each byte being 8 bits long, with the first bit cleared. This encoding is most commonly used with plain text using the US-ASCII character set, where each character is represented by a single byte in the range of 20h to 7Eh.
mailEncoding8Bit	Each character is encoded in one or more bytes, with each byte being 8 bits long and all bits are used. 8-bit encoding may be used with multi-byte character sets, although this encoding type is uncommon in email messages.
mailEncodingBinary	Binary encoding is essentially the absence of any encoding performed on the message data, and there is no presumption that the data contains textual information. No character set localization or conversion is performed on binary encoded data. This encoding type is not recommended. Instead, binary data should be encoded using the standard base64 algorithm.
mailEncodingQuoted	Quoted-printable encoding is designed for textual messages where

	most of the characters are represented by the ASCII character set and is generally human-readable. Non-printable characters or 8-bit characters with the high bit set are encoded as hexadecimal values and represented as 7-bit text. Quoted-printable encoding is typically used for messages which use character sets such as ISO-8859-1, as well as those which use HTML.
mailEncodingBase64	Base64 encoding is designed to represent binary data in a form that is not human readable but which can be safely exchanged with servers that only accept 7-bit data. Base64 encoding is typically used with file attachments.
mailEncodingUucode	Uuencoding and uudecoding is a legacy encoding format that was used before the MIME standard was established. This encoding method has largely been replaced by base64 encoding, although it is still commonly used for binary newsgroup postings on USENET. Although this encoding format is supported, it is not officially part of the MIME standard and its use in email messages is discouraged.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **CreatePart** method creates a new message part. If the current message is a simple RFC822 message, then this method converts it to a MIME multipart message. The current message part will be set to the new part that was just created.

See Also

[AttachFile Method](#), [DeletePart Method](#)

DeleteHeader Method

Delete a header field from the current message part.

Syntax

object.DeleteHeader(HeaderField)

Parameters

HeaderField

A string that specifies the name of the header field to be deleted from the current message part.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **DeleteHeader** method deletes the specified header field value from the current message part.

See Also

[ClearMesage Method](#), [GetHeader Method](#), [SetHeader Method](#)

DeleteMessage Method

Delete the specified message from the mail server.

Syntax

object.DeleteMessage([*MessageNumber*])

Parameters

MessageNumber

An optional integer value which specifies the message to delete. If this parameter is omitted, the value of the **MessageIndex** property will be used.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **DeleteMessage** method marks the specified message for deletion. If the optional message number is not specified, then the current message is deleted. Once a message has been marked as deleted, any attempt to access it will result in an error.

The message will not actually be removed from the server until the **Disconnect** method is called or the control is unloaded. To prevent messages which have been marked for deletion from actually being removed from the mailbox, call the **Reset** method.

See Also

[MessageIndex Property](#), [Disconnect Method](#), [GetHeader Method](#), [GetMessage Method](#), [Reset Method](#)

DeleteMailbox Method

Deletes a mailbox from the server.

Syntax

object.DeleteMailbox(MailboxName)

Parameters

MailboxName

A string which specifies the name of the mailbox to be deleted.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **DeleteMailbox** method deletes a mailbox from the server. A mailbox cannot be deleted if it contains inferior hierarchical names and has the **mailFlagNoSelect** attribute. On most systems this is the case when the mailbox name references a directory on the server, and that directory contains other subdirectories or mailboxes. To remove the mailbox, you must first delete any child mailboxes that exist.

If the mailbox that is deleted is the currently selected mailbox, it will be automatically unselected and any messages marked for deletion will be expunged before the mailbox is removed. If the delete operation fails, the client will remain in an unselected state until **SelectMailbox** method is called.

The special mailbox name INBOX is reserved, and cannot be deleted.

See Also

[MailboxName Property](#), [CheckMailbox Method](#), [CreateMailbox Method](#), [SelectMailbox Method](#)

DeletePart Method

Delete the specified message part in the current message.

Syntax

object.DeletePart([*MessagePart*])

Parameters

MessagePart

An optional integer value that specifies the message part to delete from the current message.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **DeletePart** method deletes the specified message part in the current message. If the optional message part is not specified, then the current message part is deleted.

See Also

[AttachFile Method](#), [CreatePart Method](#)

Disconnect Method

Disconnect from the mail server.

Syntax

object.Disconnect

Parameters

None.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **Disconnect** method causes all messages that have marked for deletion to be removed by the server and the network connection is closed.

See Also

[Connect Method](#)

ExportMessage Method

Export the current message to a text file.

Syntax

`object.ExportMessage( FileName, [Options] )`

Parameters

FileName

A string which specifies the name of the file that will contain the message. If the file does not exist, it will be created. If it does exist, it will be overwritten with the contents of the message.

Options

An optional integer value which specifies one or more options. If this argument is omitted, the **Options** property value will be used as the default. The following values may be combined using a bitwise Or operator:

Value	Description
mailOptionAllHeaders	All headers, including the Bcc, Received, Return-Path, Status and X400-Received header fields will be exported. Normally these headers are not exported because they are only used by the mail transport system. This option can be useful when exporting a message to be stored on the local system, but should not be used when exporting a message to be delivered to another user.
mailOptionKeepOrder	The original order in which the message header fields were set or imported are preserved when the message is exported.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **ExportMessage** copies the current message to the specified file. If the file does not exist it will be created, otherwise it will be overwritten with the contents of the message.

See Also

[ExtractFile Method](#), [ImportMessage Method](#)

ExtractAllFiles Method

Extract all file attachments from the current message, storing them in the specified directory.

Syntax

object.ExtractAllFiles([*Directory*])

Parameters

Directory

An optional string that specifies the name of the directory where the file attachments should be stored. If this parameter is omitted or points to an empty string, the attached files will be stored in the current working directory on the local system.

Return Value

If the method succeeds, the return value is the number of file attachments which were extracted from the current message. If the message does not contain any file attachments, this method will return a value of zero. If the method fails, the return value is -1. To get extended error information, check the value of the **LastError** property.

Remarks

This method will extract all of the files that are attached to the current message and store them in the specified directory. The directory must exist and the current user must have the appropriate permissions to create files there. If a file with the same name as the attachment already exists, it will be overwritten with the contents of the attachment. If the file attachment was encoded using base64 or uuencode, this method will automatically decode the contents of the attachment.

To store a file attachment on the local system using a name that is different than the file name of the attachment, use the **ExtractFile** method.

See Also

[Attachment Property](#), [AttachData Method](#), [AttachFile Method](#), [ExtractFile Method](#)

ExtractFile Method

Extract an attached file from the current message.

Syntax

object.ExtractFile(*FileName*, [*MessagePart*])

Parameters

FileName

A string which specifies the name of the file that the attachment will be written to. If the file does not exist, it will be created. If the file exists, it will be overwritten.

MessagePart

An optional integer value that specifies the message part that contains the file attachment.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **ExtractFile** method writes the contents of a message part, typically a file attachment, to a file on the local system. This method will automatically decode any binary file attachments. If the optional **MessagePart** argument is not specified, the current message part is used. To determine if the current message part contains an attachment and to determine its file name, check the value of the **Attachment** property. An error will be returned if the specified message part does not contain a file attachment.

To search for a file attachment in the current message with a specific file name, use the **FindAttachment** method.

See Also

[Attachment Property](#), [ExportMessage Method](#), [ExtractAllFiles Method](#), [FindAttachment Method](#)

FindAttachment Method

Search the current message for a file attachment with the specified file name.

Syntax

object.FindAttachment(*FileName*)

Parameters

FileName

A string that specifies the name of the file attachment to search for. This parameter should only specify a base file name; it should not include a file path and cannot be an empty string.

Return Value

If the method succeeds, the return value is the message part number that contains the file attachment. If the message does not contain an attachment that matches the specified file name, the return value is -1. To get extended error information, check the value of the **LastError** property.

Remarks

The **FindAttachment** method will search the current message for an attachment that matches the specified file name. The search is not case-sensitive, however it must match the attachment file name completely. This method will not match partial file names or names that include wildcard characters.

Example

```
nMessagePart = InternetMail1.FindAttachment(strFileName)

If nMessagePart > -1 Then
    InternetMail1.ExtractFile(strFileName, nMessagePart)
End If
```

See Also

[Attachment Property](#), [AttachFile Method](#), [ExtractAllFiles Method](#), [ExtractFile Method](#)

GetFirstHeader Method

Return the first header in the current message part.

Syntax

object.GetFirstHeader(*HeaderField*, *HeaderValue*)

HeaderField

A string which will contain the name of the first header field when the method returns. This parameter must be passed by reference.

HeaderValue

A string which will contain the value of the first header field when the method returns. This parameter must be passed by reference.

Return Value

A boolean value of True is returned if the method succeeds, otherwise a value of False is returned. For more information about the cause of the failure, check the value of the **LastError** property.

Remarks

The **GetFirstHeader** method allows an application to enumerate all of the headers in the current message. If the current message part does not contain any header fields, this method will return False.

Example

The following example enumerates all of the headers in the main part of the current message and adds them to a listbox:

```
Dim strHeader As String, strValue As String
Dim bResult As boolean

bResult = InternetMail1.GetFirstHeader(strHeader, strValue)
Do While bResult
    List1.AddItem strHeader & ": " & strValue
    bResult = InternetMail1.GetNextHeader(strHeader, strValue)
Loop
```

See Also

[MessagePart Property](#), [GetHeader Method](#), [GetNextHeader Method](#), [SetHeader Method](#)

GetHeader Method

Return the value for the specified header in the current message part.

Syntax

object.GetHeader(*HeaderField*, *HeaderValue*)

Parameters

HeaderField

A string variable which will specifies the name of the header field to return the value of. Header field names are not case sensitive.

HeaderValue

A string variable which will contain the value of the specified header field. This parameter must be passed by reference.

Return Value

A boolean value of True is returned if the method succeeds, otherwise a value of False is returned. For more information about the cause of the failure, check the value of the **LastError** property.

Remarks

The **GetHeader** method is used to retrieve the value for a specific header in the current message part. If the header field exists, the method will return True and the *HeaderValue* parameter will contain the header value. If the header does not exist, the method will return False.

If there are multiple headers with the same name, the first value will be returned. To enumerate all of the headers in a message, including duplicate header fields, use the **GetFirstHeader** and **GetNextHeader** methods.

See Also

[MessagePart Property](#), [GetFirstHeader Method](#), [GetNextHeader Method](#), [SetHeader Method](#)

GetNextHeader Method

Return the next header in the current message part.

Syntax

object.GetNextHeader(*HeaderField*, *HeaderValue*)

Parameters

HeaderField

A string which will contain the name of the next header field when the method returns. This parameter must be passed by reference.

HeaderValue

A string which will contain the value of the next header field when the method returns. This parameter must be passed by reference.

Return Value

A boolean value of True is returned if the method succeeds, otherwise a value of False is returned. For more information about the cause of the failure, check the value of the **LastError** property.

Remarks

The **GetNextHeader** method allows an application to enumerate all of the headers in the current message. When all of the headers in the current message part have been returned, this method will return False.

Example

The following example enumerates all of the headers in the main part of the current message and adds them to a listbox:

```
Dim strHeader As String, strValue As String
Dim bResult As boolean

bResult = InternetMail1.GetFirstHeader(strHeader, strValue)
Do While bResult
    List1.AddItem strHeader & ": " & strValue
    bResult = InternetMail1.GetNextHeader(strHeader, strValue)
Loop
```

See Also

[MessagePart Property](#), [GetFirstHeader Method](#), [GetHeader Method](#), [SetHeader Method](#)

GetMessage Method

Retrieve the specified message from the mail server.

Syntax

object.GetMessage([*MessageNumber*])

Parameters

MessageNumber

An optional integer value that specifies the message number.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **GetMessage** method retrieves the specified message from the mail server. This method will cause the current message to be replaced with the new message, and the **MessageIndex** property will be updated with the new message number. If the optional message *MessageNumber* argument is not specified, then the value of the **MessageIndex** property is used instead.

Note that unlike setting the **MessageIndex** property, which only causes the headers for the specified message to be retrieved, the **GetMessage** method downloads the complete message. The **OnProgress** event will fire periodically as the message is retrieved, allowing an application to update its user interface if desired.

Example

The following example connects to a mail server and retrieves the first message:

```
Dim nError As Long

nError = InternetMail1.Connect(strServerName, , strUserName, strPassword)

If nError > 0 Then
    MsgBox "Unable to connect to " & strServerName & vbCrLf & _
        InternetMail1.LastErrorString, vbExclamation
    Exit Sub
End If

If InternetMail1.LastMessage = 0 Then
    MsgBox "The mailbox is currently empty", vbInformation
    InternetMail1.Disconnect
    Exit Sub
End If

nError = InternetMail1.GetMessage(1)

If nError > 0 Then
    MsgBox "Unable to retrieve the message" & vbCrLf & _
        InternetMail1.LastErrorString, vbExclamation
Next

InternetMail1.Disconnect
```

See Also

[MessageIndex Property](#), [GetHeader Method](#), [OnProgress Event](#)

Idle Method

Enables mailbox status monitoring for the client session.

Syntax

object.Idle([Options], [Timeout])

Parameters

Options

An optional integer value which specifies how the **Idle** method will function. If this argument is omitted, the method will return immediately to the caller without causing the current thread to block.

Value	Description
mailIdleNoWait	The method should return immediately after idle processing has been enabled. When this option is used, the application may continue to perform other functions while the client session is monitored for status updates sent by the server. The client will continue to monitor status changes until an IMAP command issued or the client disconnects from the server. This is the default option.
mailIdleWait	The method should wait until the server sends a status update, or until the timeout period is reached. The client will stop monitoring status changes when the function returns. If this option is used in a single-threaded application, normal message processing can be impeded, causing the application to appear non-responsive until the timeout period is reached. It is strongly recommended that single-threaded applications with a user interface specify the mailIdleNoWait option instead.

Timeout

Specifies the timeout period in seconds to wait for a notification from the server. This parameter is only used when the **mailIdleWait** option has been specified.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **Idle** method enables mailbox status monitoring for the client session, allowing the client to receive notifications from the server whenever a new message arrives or a message is expunged from the currently selected mailbox. This is typically used as an alternative to the client periodically polling the server for status information.

Many IMAP servers support the ability to asynchronously send status updates to the client, rather than have the client periodically poll the server. The client enables this feature by calling the **Idle** method and implementing an event handler for the **OnUpdate** event. Typically these events inform the client that a new message has arrived or that a message has been expunged from the mailbox.

The **Idle** method can operate in two modes, based on the options specified by the caller. If the option **mailIdleNoWait** is specified, the method begins monitoring the client session asynchronously and returns control immediately to the caller. If the server sends a update notification to the client, the

OnUpdate event will fire with information about the status change. If the option **mailIdleWait** is specified, the method will block waiting for the server to send a notification message to the client. The method will return when either a message is received or the timeout period is exceeded.

Sending an IMAP command to the server will cause the client to stop monitoring the session for status changes. To explicitly stop monitoring the session, use the **Cancel** method.

This method works by sending the IDLE command to the server and starting a worker thread which monitors the connection and looks for untagged responses issued by the server. Events will be generated for EXISTS, EXPUNGE and RECENT messages. Note that some servers may periodically send untagged OK messages to the client, indicating that the connection is still active; these messages are explicitly ignored.

An application should never make an assumption about how a particular server may send update notifications to the client. Servers can be configured to use different intervals at which notifications are sent. For example, a server may send new message notifications immediately, but may periodically notify the client when a message has been expunged. Alternatively, a server may only send notifications at fixed intervals, in which case the client would not be notified of any new messages until the interval period is reached. It is not possible for a client to know what a particular server's update interval is. Applications that require that degree of control should not use the **Idle** method and should poll the server instead.

This method should only be used when connected to an IMAP server. Attempting to use this method when connected to a POP3 server will fail with an error message indicating that the feature is not supported.

See Also

[OnUpdate Event](#)

ImportMessage Method

Import a new message from the specified text file.

Syntax

object.ImportMessage(FileName)

Parameters

FileName

A string that specifies the name of the file to import the message from.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **ImportMessage** method replaces the current message with the message contained in the specified text file. Note that calling this method will result in the **Bcc** property value being cleared.

See Also

[Bcc Property](#), [AttachFile Method](#), [ExportMessage Method](#), [ExtractFile Method](#)

Initialize Method

Initialize the control and validate the runtime license key.

Syntax

```
object.Initialize( [LicenseKey] )
```

Parameters

LicenseKey

An optional string value which specifies a runtime license key used to initialize the control. If the license key is omitted or passed as an empty string, a development license must be installed on the local system.

Return Value

A value of zero is returned if the control was initialized successfully. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

This method dynamically loads other system libraries and allocates thread local storage. In most cases, it is not necessary to call this method directly because it is automatically invoked when an instance of the control is created by the container. However, if the control is created dynamically using **CreateObject** or a similar method, this must be the first method that is called before you attempt to modify any property values or invoke other methods. Failure to initialize the control may result in subsequent errors and/or cause an exception to be raised.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the control will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the control was created.

If the control is being used within another DLL, it is important that you do not attempt to create an instance of the control or call the **Initialize** method from within the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is written in C++ and it is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for any static and global C++ objects and has the same restrictions.

Example

```
Set mailClient = CreateObject("SocketTools.InternetMail.12")

nError = mailClient.Initialize(strLicenseKey)
If nError > 0 Then
    MsgBox "Unable to initialize SocketTools component"
End
End If
```

See Also

[IsInitialized Property](#), [Uninitialize Method](#)

ParseAddress Method

Parse an Internet email address.

Syntax

object.ParseAddress(*Address*)

Parameters

Address

A string value that specifies the address to be parsed.

Return Value

A string that contains the email address or an empty string if the address could not be parsed.

Remarks

The **ParseAddress** method parses a string which contains an email address and returns only the address portion, excluding any comments. An address may contain comments enclosed in parenthesis, or may specify a name along with the address in which case the address is enclosed in angle brackets. For example, consider the following header field value:

"User Name" <user@domain.com> (This is a comment)

The string "user@domain.com" would be returned if passed the above string, removing the name and any comments.

Note that the **ParseAddress** method will only parse a single address. If multiple addresses are specified, they must be comma delimited and split prior to calling this method.

Example

The following example parses all of the recipient email addresses in the current message, storing them in the *strAddresses* string array.

```
Dim strAddresses() As String, strAddress As String
Dim nIndex As Integer, nAddresses As Integer

nAddresses = 0
strAddresses = Split(InternetMail1.To & "," & _
                    InternetMail1.Cc & "," & _
                    InternetMail1.Bcc, ",")

For nIndex = 0 To UBound(strAddresses)
    If Len(Trim(strAddresses(nIndex))) > 0 Then
        strAddress = InternetMail1.ParseAddress(strAddresses(nIndex))
        If Len(strAddress) > 0 Then
            strAddresses(nAddresses) = strAddress
            nAddresses = nAddresses + 1
        End If
    End If
Next
```

See Also

[Recipient Property](#), [Recipients Property](#), [ParseMessage Method](#)

ParseMessage Method

Parse the specified string, adding the contents to the current message.

Syntax

object.ParseMessage(*MessageText*)

Parameters

MessageText

A string which specifies the message text to be parsed.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **ParseMessage** method parses a string which contains message data, adding it to the current message. This method is useful when the application needs to parse an arbitrary block of text and add it to the current message. If the string contains header fields, the values will be added to the message header. Once the end of the header block is detected, all subsequent text is added to the body of the message.

Note that unlike the **ImportMessage** method, the **ParseMessage** method does not clear the contents of the current message and may be called multiple times. Use the **ClearMessage** method to clear the current message before calling **ParseMessage** if necessary.

Example

The following example demonstrates the use of **ParseMessage** to parse multiple blocks of data from a file. This example effectively does the same thing as calling the **ImportMessage** method:

InternetMail1.ClearMessage

```
hFile = FreeFile()
Open strFileName For Input As hFile
nFileLength = LOF(hFile)

Do While nFileLength > 0
    '
    ' Read the contents of the file in 1K blocks; note that
    ' this is intentionally inefficient to demonstrate
    ' multiple calls to the ParseMessage method.
    '
    cbBuffer = nFileLength: If cbBuffer > 1024 Then cbBuffer = 1024
    nFileLength = nFileLength - cbBuffer
    strBuffer = Input(cbBuffer, hFile)
    '
    ' Parse the string, adding to the current message
    '
    nError = InternetMail1.ParseMessage(strBuffer)
    If nError > 0 Then
        MsgBox InternetMail1.LastErrorString, vbExclamation
        Exit Do
    End If
Loop
```

Close hFile

See Also

[ClearMessage Method](#), [ImportMessage Method](#)

RenameMailbox Method

Change the name of a mailbox.

Syntax

object.RenameMailbox(*OldName*, *NewName*)

Parameters

OldName

A string that specifies the name of the mailbox to be renamed on the server. The mailbox must exist on the server, otherwise an error will be returned.

NewName

A string that specifies the new name for the mailbox. An error will be returned if a mailbox with that name already exists.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

If the existing mailbox name contains inferior hierarchical names (mailboxes under the specified mailbox) then those mailboxes will also be renamed. For example, if the mailbox "Mail/Pictures" contains two mailboxes, "Personal" and "Work" and it is renamed to "Mail/Images" then the two mailboxes under it would be automatically renamed to "Mail/Images/Personal" and "Mail/Images/Work".

If the mailbox being renamed is the currently selected mailbox, the current mailbox will be unselected and any messages marked for deletion will be expunged. The new mailbox name will then automatically be re-selected. To prevent deleted messages from being removed from the mailbox prior to being renamed, use the **UnselectMailbox** method to unselect the current mailbox before calling **RenameMailbox**. Note that if the rename operation fails, the client may be left in an unselected state.

It is permitted to rename the special mailbox INBOX. In this case, the messages will be moved from the INBOX mailbox to the new mailbox. If the INBOX mailbox is currently selected, the new mailbox will not automatically be selected. INBOX will remain the selected mailbox.

See Also

[Mailbox Property](#), [Mailboxes Property](#), [MailboxName Property](#), [SelectMailbox Method](#)

Reset Method

Reset the state of the component.

Syntax

object.Reset

Parameters

None.

Return Value

None.

Remarks

The **Reset** method resets the internal state of the component, releasing any memory allocated for messages and/or network connections. If the application is connected to a mail server, the connection will be terminated. If any messages were marked for pending deletion, those messages will not be deleted.

See Also

[Cancel Method](#)

SearchMailbox Method

Search the current mailbox for messages that match the specified criteria.

Syntax

object.SearchMailbox(*Criteria*, *Messages*, [*CharacterSet*])

Parameters

Criteria

A string which consists of one or more keywords which are used to define the search criteria. The following keywords are recognized:

Keyword	Description
ANSWERED	Match those messages which have the mailFlagAnswered flag set.
BCC <i>address</i>	Match those messages which contain the specified address in the BCC header field.
BEFORE <i>date</i>	Match those messages which were added to the mailbox prior to the specified date.
BODY <i>string</i>	Match those messages where the body contains the specified string.
CC <i>address</i>	Match those messages which contain the specified address in the CC header field.
DELETED	Match those messages which have the mailFlagDeleted flag set.
DRAFT	Match those messages which have the mailFlagDraft flag set.
FLAGGED	Match those messages which have the mailFlagUrgent flag set.
FROM <i>address</i>	Match those messages which contain the specified address in the FROM header field.
HEADER <i>field string</i>	Match those messages which contain the string in the specified header field. If no string is specified, then all messages which contain the header will be matched.
LARGER <i>size</i>	Match those messages which are larger than the specified size in bytes.
NEW	Match those messages which have the mailFlagRecent flag set, but not the mailFlagSeen flag.
OLD	Match those messages which do not have the mailFlagRecent flag set.
ON <i>date</i>	Match those messages which were added on the specified date.
RECENT	Match those messages which have the mailFlagRecent flag set.
SEEN	Match those messages which have the mailFlagSeen flag set.
SENTBEFORE <i>date</i>	Match those messages whose Date header value is earlier than the specified date.
SENTON <i>date</i>	Match those messages whose Date header value is the same as the specified date.
SENTSINCE	Match those messages whose Date header value is later than the

<i>date</i>	specified date.
SINCE <i>date</i>	Match those messages added to the mailbox after the specified date.
SMALLER <i>size</i>	Match those messages which are smaller than the specified size in bytes.
SUBJECT <i>string</i>	Match those messages whose Subject header contains the specified string.
TEXT <i>string</i>	Match those messages whose headers or body contains the specified string.
TO <i>address</i>	Match those messages which contain the specified address in the TO header field.
UID <i>sequence</i>	Match those messages with unique identifiers in the sequence set.
UNANSWERED	Match those messages which do not have the mailFlagAnswered flag set.
UNDELETED	Match those messages which do not have the mailFlagDeleted flag set.
UNDRAFT	Match those messages which do not have the mailFlagDraft flag set.
UNFLAGGED	Match those messages which do not have the mailFlagUrgent flag set.
UNSEEN	Match those messages which do not have the mailFlagSeen flag set.

Messages

This argument must be passed as an array of integers which will contain the message numbers of those messages which match the search criteria. The size of the array determines the maximum number of matches that will be returned by the method. Note that the array must specify 32-bit integers. In Visual Basic, this means that the array would be typed as Long. In Visual Basic.NET, the array would be typed as Integer.

CharacterSet

An optional string which specifies the character set to use when searching the mailbox. If this argument is omitted, the default UTF-8 character set will be used. Note that not all servers support searches using anything but the default character set.

Return Value

This method will return the number of messages which were found to match the search criteria. If no messages match the criteria, then the return value will be zero. A return value of -1 indicates an error, and the specific error code can be determined by checking the **LastError** property.

Remarks

The **SearchMailbox** method is used to search a mailbox for messages which match a given criteria and return a list of the matching message numbers. The search criteria is composed of one or more search keywords and an optional value to match against. String searches are not case sensitive and partial matches in the message are returned. The message numbers returned by this method are only valid until the mailbox is expunged or another mailbox is selected.

In addition to the listed keywords, the keyword NOT may prefix a keyword to return those messages which do not match the search criteria. For example, "NOT TO user@domain.com" would return those messages which were not addressed to user@domain.com.

If multiple search keywords are specified, the result is the intersection of all those messages which meet the search criteria. For example, a search criteria of "DELETED SINCE 1-Jan-2010" would return

all those messages which are marked for deletion and were added to the mailbox after 1 January 2010.

Those search keywords which expect dates must be specified in format *dd-mmm-yyyy* where the month is the three letter abbreviation for the month name. Note that the internal date the message was added to the mailbox is not the same as the value of the Date header field in the message.

If the search keyword expects a string value and the string contains one or more spaces, you need to enclose the search string in quotes as part of the criteria string. For example, in Visual Basic you could use code like this:

```
strCriteria = "SUBJECT " + Chr(34) + "search string" + Chr(34)
```

The quotes around the search string prevents the server from interpreting it as a multiple search criteria to be evaluated. If you are using a search string provided by a user, it is recommended that you always enclose it in quotes to prevent any potential ambiguity in the search. Even if the search string does not contain any spaces, it is always safe to enclose it in quotes.

The UID keyword expects a one or more unique message identifiers. These values may provided as comma separated list, or a range delimited by a colon. For example, "UID 23000:24000" would return all those messages who have UIDs ranging from 23000 through to 24000.

See Also

[MailboxName Property](#), [SelectMailbox Method](#)

SelectMailbox Method

Selects the specified mailbox for read-write access.

Syntax

object.SelectMailbox(*MailboxName*)

Parameters

MailboxName

A string argument which specifies the name of the mailbox to be selected.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **SelectMailbox** method is used to select a mailbox in read-write mode. If the client has a different mailbox currently selected, that mailbox will be closed and any messages marked for deletion will be expunged. To prevent deleted messages from being removed from the previous mailbox, use the **UnselectMailbox** method prior to selecting the new mailbox.

The special case-insensitive mailbox name INBOX is used for new messages. Other mailbox names may or may not be case-sensitive depending on the IMAP server's operating system and implementation.

See Also

[MailboxName Property](#), [CheckMailbox Method](#), [UnselectMailbox Method](#)

SendMessage Method

Send an email message to one or more recipients.

Syntax

object.SendMessage([*Sender*], [*Recipient*], [*Message*], [*Options*])

Parameters

Sender

An optional string value that identifies the sender of the message and must be a standard Internet email address. If this argument is omitted, then the address specified by the **From** property will be used.

Recipient

An optional string value that specifies one or more recipients of the message. If this argument is omitted, then the addresses listed in the **Bcc**, **Cc** and **To** properties will be combined to determine the recipients of the message.

Message

An optional string value that contains a complete email message. This must be a properly formatted message that conforms to the standards for Internet email. If this argument is omitted, then the current message is sent.

Options

An optional integer value that specifies one or more options for sending the message. If this argument is omitted, the value of the **Options** property will be used instead. One or more of the following values may be used:

Value	Description
mailOptionSecureImplicit	This option specifies that an implicit TLS session should be established with the mail server and prevents the use of a command which is used to negotiate an explicit TLS connection.
mailOptionAuthLogin	Specifies that the user must be authenticated to the mail server before the message is delivered. This option should only be used if a relay server supports AUTH LOGIN and requires authentication.
mailOptionNotify	Notify the sender of the delivery status of the message, if the server supports delivery status notification. This option is a combination of the <i>mailNotifySuccess</i> , <i>mailNotifyFailure</i> , <i>mailNotifyDelay</i> and <i>mailReturnHeaders</i> options.
mailNotifySuccess	If the mail server supports delivery status notification, this causes a message to be returned to the sender once it has been successfully delivered.
mailNotifyFailure	If the mail server supports delivery status notification, this causes a message to be returned to the sender if it could not be delivered.
mailNotifyDelay	If the mail server supports delivery status notification, this causes a message to be returned to the sender if delivery has been

	delayed.
mailReturnHeaders	If the mail server supports delivery status notification, this causes a message to be returned which contains the headers of the message that was sent.
mailReturnMessage	If the mail server supports delivery status notification, this causes a message to be returned which contains the complete message that was sent.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **SendMessage** method sends the specified message to one or more recipients. This method can be used in a number of different ways, depending on the arguments specified by the caller.

If the **Message** parameter is specified, but the **sender** and **recipient** properties are omitted, then the message will be parsed and the addresses will be automatically determined by the values of the From, Cc and To header fields. Note that specifying a **message** argument does not change the current message.

For each recipient listed, either as an argument to the method or in the message itself, the **SendMessage** method will determine the appropriate mail exchange server and deliver the message to that user. If the **RelayServer** and **RelayPort** properties are defined, then all messages will be relayed through that specific server, regardless of the recipient address. Note that the **Secure** property and related options only affects connections to relay mail servers. See the **RelayServer** and **RelayPort** properties for additional information.

If a relay server is being used, it may require authentication before accepting any messages for delivery. To enable authentication, specify the **mailOptionAuthLogin** option, either as an argument or by setting the **Options** property. Prior to calling the **SendMessage** method, the **UserName** and **Password** properties should be set to the values that will be used to authenticate the session. If the server does not support authentication, or the user name or password is invalid, an error will be returned. Note that authentication is only performed if a relay server is used, otherwise the option is ignored.

[Bcc Property](#), [Cc Property](#), [From Property](#), [RelayPort Property](#), [RelayServer Property](#), [Secure Property](#), [To Property](#)

SetHeader Method

Set the value of a header field in the current message part.

Syntax

object.SetHeader(HeaderField, HeaderValue)

Parameters

HeaderField

A string which specifies the name of the header field to create or modify. If the header field does not exist, then it will be created. If the header field does exist, the value will be overwritten.

HeaderValue

A string which specifies the value of the specified header field.

Return Value

A boolean value of True is returned if the method succeeds, otherwise a value of False is returned. For more information about the cause of the failure, check the value of the **LastError** property.

Remarks

The **SetHeader** method creates or changes the value of the specified header field in the current message part. If the header does not exist, it will be created with the new value. If the header does exist, its current value will be replaced by the new value.

See Also

[MessagePart Property](#), [GetFirstHeader Method](#), [GetHeader Method](#), [GetNextHeader Method](#)

StoreMessage Method

Store the specified message in a file.

Syntax

object.StoreMessage(*MessageNumber*, *FileName*)

Parameters

MessageNumber

An integer value which specifies the message to store.

FileName

A string value that specifies the name of the file to store the message in.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **StoreMessage** method retrieves the specified message from the mail server and stores it in a file. The *number* argument specifies the message to retrieve and the *filename* argument specifies the name of the file that the message will be stored in.

For applications which need to store messages on the local system, the **StoreMessage** method is somewhat more efficient than using the **GetMessage** and **ExportMessage** methods to load and store the message. **StoreMessage** does not attempt to analyze the message or change the current message contents.

Example

The following example connects to a mail server and retrieves each of the mail messages, storing them in a file on the local system:

```
Dim strFileName As String
Dim nMessage As Long, nError As Long

nError = InternetMail1.Connect(strServerName, , strUserName, strPassword)

If nError > 0 Then
    MsgBox "Unable to connect to " & strServerName & vbCrLf & _
        InternetMail1.LastErrorString, vbExclamation
    Exit Sub
End If

If InternetMail1.LastMessage = 0 Then
    MsgBox "The mailbox is currently empty", vbInformation
    InternetMail1.Disconnect
    Exit Sub
End If

For nMessage = 1 To InternetMail1.LastMessage
    strFileName = "c:\temp\msg" & Format(nMessage, "00000") & ".txt"
    nError = InternetMail1.StoreMessage(nMessage, strFileName)
    If nError > 0 Then
        MsgBox "Unable to store message " & nMessage & vbCrLf & _
```

```
        InternetMail1.LastErrorString, vbExclamation
    Exit For
End If
Next

If nError = 0 Then
    MsgBox "Stored " & InternetMail1.LastMessage & " messages", vbInformation
End If

InternetMail1.Disconnect
```

UndeleteMessage Method

Removes the deletion flag for the specified message.

Syntax

object.UndeleteMessage(*MessageNumber*)

Parameters

MessageNumber

Number of message to undelete from the server. This value must be greater than zero. The first message in the mailbox is message number one.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **UndeleteMessage** method removes the deletion flag for the specified message in the current mailbox. To determine if a message has been marked for deletion, set the **MessageIndex** property to the message number and then check the value of the **MessageFlags** property to determine if the **mailFlagDeleted** bit flag has been set.

This method can only be used when connected to an IMAP server.

[MessageFlags Property](#), [MessageIndex Property](#), [DeleteMessage Method](#), [SelectMailbox Method](#)

Uninitialize Method

Uninitialize the control and release any system resources that were allocated.

Syntax

object.Uninitialize

Parameters

None.

Return Value

None.

Remarks

The **Uninitialize** method terminates any connection established by the control and resets the internal state of the control. This method is not typically used because any resources that have been allocated by an instance of the control will automatically be released when it is destroyed.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the control will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the control was created. An application should only call the **Uninitialize** method if it has explicitly called the **Initialize** method.

See Also

[Initialize Method](#)

UnselectMailbox Method

Unselects the current mailbox.

Syntax

object.UnselectMailbox([*Expunge*])

Parameters

Expunge

An optional boolean argument which determines if deleted messages will be expunged from the mailbox. A value of true specifies that messages that have been marked for deletion will be removed from the mailbox. A value of False specifies that no messages will be removed from the mailbox. If this argument is omitted, the default action is to expunge deleted messages from the mailbox.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **UnselectMailbox** method unselects the current mailbox. Once the mailbox has been unselected, no messages in that mailbox can be accessed, and by default any messages which have been marked for deletion are removed.

Internet Mail Control Events

Event	Description
OnCancel	This event occurs when an operation is canceled
OnDelivered	This event occurs after a message has been delivered
OnError	This event occurs when an error occurs
OnProgress	This event occurs when retrieving or sending messages
OnRecipient	This event occurs before a message is sent
OnTimeout	This event occurs when an operation is canceled
OnUpdate	This event occurs when the server sends a mailbox update notification to the client

OnCancel Event

The **OnCancel** event is generated when an operation is canceled.

Syntax

Private Sub *object_OnCancel* (*[Index As Integer]*)

Remarks

The **OnCancel** event is generated after an operation is canceled by calling the **Cancel** method.

See Also

[OnError Event](#), [Cancel Method](#)

OnDelivered Event

The **OnDelivered** event is generated after a message has been delivered.

Syntax

Private Sub *object_OnDelivered***(***[Index As Integer,] ByVal Address As Variant, ByVal MessageSize As Variant***)**

Remarks

The **OnDelivered** event is generated after a message has been successfully submitted to the mail server for delivery. When used in conjunction with the **OnRecipient** and **OnProgress** events, this event can be used to track the delivery of a message to multiple recipients. If the message was not delivered, either because delivery was canceled in the **OnRecipient** event or because of an error, the **OnDelivered** event will not fire.

The **Address** argument is a string which specifies the recipient email address.

The **MessageSize** argument is a long integer which specifies the size of the message that was delivered.

Note that even though a message has been successfully delivered to the mail server, it may not actually be delivered to the recipient. The server may accept the message and then subsequently decide to reject or re-route the message based on its own internal configuration. To confirm message delivery to the actual user, use the delivery status notification options and/or set the **ReturnReceipt** property to an address which will be notified when the message has been read.

See Also

[OnProgress Event](#), [OnRecipient Event](#), [ReturnReceipt Property](#)

OnError Event

The **OnError** event is generated when an error occurs.

Syntax

Private Sub *object_OnError* (*[Index As Integer,] ByVal Error As Variant, ByVal Description As Variant*)

Remarks

The **OnError** event is generated when an error occurs while the component is performing an operation. Visual Basic errors do not generate this event.

The **ErrorCode** argument specifies the last error that has occurred. If the error is network related, the error code values returned by the component correspond to those returned by the standard Windows Sockets library.

The **Description** argument is a string that describes the error. This corresponds to the **LastErrorString** property.

See Also

[LastError Property](#), [LastErrorString Property](#)

OnProgress Event

The **OnProgress** event is generated when retrieving or sending messages.

Syntax

Private Sub *object_OnProgress* (*[Index As Integer,] ByVal MessageSize As Variant, ByVal MessageCopied As Variant, ByVal Percent As Variant*)

Remarks

The **OnProgress** event is generated when a message is being retrieved or sent. This event can be used to update the user interface, such as displaying a progress bar during the transaction. To cancel the current operation, the application can call the **Cancel** method from within this event.

The **MessageSize** argument is a long integer which specifies the size of the message in bytes that is currently being sent or received.

The **MessageCopied** argument is a long integer which specifies the number of bytes that have been sent or received for the current message.

The **Percent** argument is an integer which specifies the completion percentage between a value of 0 and 100.

See Also

[Cancel Method](#)

OnRecipient Event

The **OnRecipient** event is generated before a message is sent.

Syntax

Private Sub *object_OnRecipient* ([*Index As Integer*,] *ByVal Address As Variant*, *ByRef Cancel As Variant*)

Remarks

The **OnRecipient** event is generated immediately before a message is sent to a recipient. When used in conjunction with the **OnProgress** event, this event can be used to track the delivery of a message to multiple recipients. If an error occurs during the delivery of the message, the **OnError** event will fire.

The **Address** argument is a string which specifies the recipient email address.

The **Cancel** argument determines whether or not the message delivery is canceled for the specified recipient. Setting this argument to a value of true causes the **SendMessage** method to not deliver the message and continue on to the next recipient. The default value for this argument is False, which indicates that the message should be delivered.

Note that setting the **Cancel** argument to True is different from using the **Cancel** method, which would cancel delivery of the message to all subsequent recipients as well as the current recipient specified by the **Address** argument.

See Also

[Cancel Method](#), [OnProgress Event](#), [OnError Event](#), [SendMessage Method](#)

OnTimeout Event

The **OnTimeout** event is generated when an operation is canceled.

Syntax

Private Sub *object_OnTimeout* (*[Index As Integer]*)

Remarks

The **OnTimeout** event is generated after an operation times out. The amount of time that the component will wait for an operation to complete can be controlled by the **Timeout** property.

See Also

[Timeout Property](#), [OnCancel Event](#)

OnUpdate Event

The **OnUpdate** event is generated when the server sends a mailbox update notification to the client.

Syntax

Sub *object_OnUpdate* ([*Index As Integer*], **ByVal** *UpdateType As Variant*, **ByVal** *MessageNumber As Variant*)

Remarks

The **OnUpdate** event is generated when the server sends a notification to the client that a new message has been stored in the mailbox, or when a message has been expunged from the mailbox. The arguments to this event are:

UpdateType

An integer value which specifies the type of update notification that has been sent by the server. It may be one of the following values:

Value	Description
mailUpdateUnknown	The server has sent an unrecognized notification message. The value of the MessageNumber argument is undefined for this type of notification. This does not necessarily reflect an error condition, as some servers may send additional notification messages beyond the standard EXISTS, EXPUNGE and RECENT messages. Most applications should ignore this type of notification.
mailUpdateMessage	The server has sent notification message to the client indicating that a new message has arrived. The MessageNumber argument will contain the message number for the new message. Typically this update notification occurs shortly after the new message has been stored in the current mailbox.
mailUpdateExpunge	The server has sent a notification message to the client indicating that a message has been removed from the current mailbox. The MessageNumber argument will contain the message number for the message that has been removed. It is recommended that the application re-examine the mailbox when this notification is received. Typically this notification is only sent periodically by the server, and may not be sent immediately after a message has been expunged from the mailbox.
mailUpdateMailbox	The server has sent notification message to the client indicating that the state of the mailbox has changed. The MessageNumber argument is not used with this notification. This message is sent periodically by the server and may not be sent immediately after a new message arrives or a message is flagged as unread. It is recommended that the application re-examine the mailbox when this notification is received.

MessageNumber

An integer value which specifies the message number associated with the status change. Note that this argument is not used with the **imapUpdateMailbox** notification and will contain a value of

zero.

This event is only generated when the **Idle** method has been used to enable mailbox status monitoring.

[Idle Method](#)

Message Character Sets

Value	Name	Code Page	Description
mimeCharsetUSASCII	us-ascii		A character set which defines 7-bit printable characters with values ranging from 20h to 7Eh. An application that uses this character set has the broadest compatibility with most mail servers (MTAs) because it does not require the server to handle 8-bit characters correctly when the message is delivered.
mimeCharsetISO8859_1	iso-8859-1		A character set for most western European languages such as English, French, Spanish and German. This character set is also commonly referred to as Latin-1. This character set is similar to Windows code page 1252 (Windows-1252), however there are differences such as the Euro symbol.
mimeCharsetISO8859_2	iso-8859-2		A character set for most central and eastern European languages such as Czech, Hungarian, Polish and Romanian. This character set is also commonly referred to as Latin-2. This character set is similar to Windows code page 1250, however the characters are arranged differently.
mimeCharsetISO8859_3	iso-8859-3		A character set for southern European languages such as Maltese and Esperanto. This character set was also used with the Turkish language, but it was superseded by ISO 8859-9 which is the preferred character set for Turkish. This character set is not widely used in mail messages and it is recommended that you use UTF-8 instead.
mimeCharsetISO8859_4	iso-8859-4		A character set for northern European languages such as Latvian, Lithuanian and Greenlandic. This character set is

		not widely used in mail messages and it is recommended that you use UTF-8 instead.
mimeCharsetISO8859_5	iso-8859-5	A character set for Cyrillic languages such as Russian, Bulgarian and Serbian. This character set was never widely adopted and most mail messages use either KOI8 or UTF-8 encoding.
mimeCharsetISO8859_6	iso-8859-6	A character set for Arabic languages. Note that the application is responsible for displaying text that uses this character set. In particular, any display engine needs to be able to handle the reverse writing direction and analyze the context of the message to correctly combine the glyphs.
mimeCharsetISO8859_7	iso-8859-7	A character set for the Greek language. This character set is also commonly referred to as Latin/Greek. This character set is no longer widely used and has largely been replaced with UTF-8 which provides more complete coverage of the Greek alphabet.
mimeCharsetISO8859_8	iso-8859-8	A character set for the Hebrew language. Note that similar to Arabic, Hebrew uses a reverse writing direction. An application which displays this character should be capable of processing bi-directional text where a single message may include both right-to-left and left-to-right languages, such as Hebrew and English. In most cases it is recommended that you use UTF-8 instead of this character set.
mimeCharsetISO8859_9	iso-8859-9	A character set for the Turkish language. This character set is also commonly referred to as Latin-5. This character set is nearly identical to ISO 8859-1, except that it replaces certain Icelandic characters with Turkish characters.

mimeCharsetISO8859_10	iso-8859-10	A character set for the Danish, Icelandic, Norwegian and Swedish languages. This character set is also commonly referred to as Latin-6 and is similar to ISO 8859-4.
mimeCharsetISO8859_13	iso-8859-13	A character set for Baltic languages. This character set is also commonly referred to as Latin-7. This character set is similar to ISO 8859-4, except it adds certain Polish characters and does not support Nordic languages.
mimeCharsetISO8859_14	iso-8859-14	A character set for Gaelic languages such as Irish, Manx and Scottish Gaelic. This character set is also commonly referred to as Latin-8. This character set replaced ISO 8859-12 which was never fully implemented.
mimeCharsetISO8859_15	iso-8859-15	A character set for western European languages. This character set is also commonly referred to as Latin-9 and is nearly identical to ISO8859-1 except that it replaces lesser-used symbols with the Euro sign and some letters.
mimeCharsetISO2022_JP	iso-2022-jp	A multi-byte character encoding for Japanese that is widely used with mail messages. This is a 7-bit encoding where all characters start with ASCII and uses escape sequences to switch to the double-byte character sets.
mimeCharsetISO2022_KR	iso-2022-kr	A multi-byte character encoding for Korean which encodes both ASCII and Korean double-byte characters. This is a 7-bit encoding which uses the shift in and shift out control characters to switch to the double-byte character set.
mimeCharsetISO2022_CN	x-cp50227	A multi-byte character encoding for Simplified Chinese which encodes both ASCII and Chinese double-byte characters. This is a 7-bit encoding which uses the shift in

		and shift out control characters to switch to the double-byte character set.
mimeCharsetKOI8R	koi8-r	A character set for Russian using the Cyrillic alphabet. This character set also covers the Bulgarian language. Most mail messages in the Russian language use this character set or UTF-8 instead of ISO 8859-5, which was never widely adopted.
mimeCharsetKOI8U	koi8-u	A character set for Ukrainian using the Cyrillic alphabet. This character set is similar to the KOI8-R character set, but replaces certain symbols with Ukrainian letters. Most mail messages in the Ukrainian language use this character set or UTF-8 instead of ISO 8859-5, which was never widely adopted.
mimeCharsetGB2312	x-cp20936	A multi-byte character encoding which can represent ASCII and simplified Chinese characters. It has been superseded by GB18030, however it remains widely used in China.
mimeCharsetGB18030	gb18030	A Unicode transformation format which can represent all Unicode code points and supports both simplified and traditional Chinese characters. It is backwards compatible with GB2312 and supersedes that character set.
mimeCharsetBIG5	big5	A multi-byte character set that supports both ASCII characters and traditional Chinese characters. It is widely used in Taiwan, Hong Kong and Macau. It is no longer commonly used in China, which has developed GB18030 as a standard encoding. Microsoft's implementation of Big5 on Windows does not support all of the extensions and is missing certain code points.
mimeCharsetUTF7	utf-7	A Unicode transformation format

		that uses variable-length character encoding to represent Unicode text as a stream of ASCII characters that are safe to transport between mail servers that only support 7-bit printable characters. It is primarily used as an alternative to UTF-8 when quoted-printable or base64 encoding is not desired.	
mimeCharsetUTF8	utf-8	A Unicode transformation format that uses multi-byte character sequences to represent Unicode text. It is backwards compatible with the ASCII character set, however because it uses 8-bit text, it is recommended that you use either quoted-printable or base64 encoding to ensure compatibility with mail servers that do not support 8-bit characters.	
mimeCharsetUTF16	utf-16le	N/A	A 16-bit Unicode format that represents each character as a 16-bit value in little endian byte order. This character set is not widely used in mail messages and it is recommended that you use UTF-8 instead. UTF-16 characters in big endian byte order are not supported.

Remarks

When composing a new message, it is recommended that you always use UTF-8 as the character set encoding which ensures broad compatibility with most applications. The other character sets are primarily used when parsing messages generated by other applications. Internally, all message headers and text are processed as UTF-8 and returned as Unicode strings.

In addition to the character sets listed above, the control will recognize additional character sets which correspond to specific Windows code pages, as well several variants. These additional character sets are included for compatibility with other applications; they are not defined because they should not be used when composing new messages.

It is important to note that while certain Windows character sets are similar to standard ISO character sets, they are not identical. For example, although the Windows-1252 character set is nearly identical to ISO 8859-1, they are not interchangeable. Some legacy applications make the error of representing Windows ANSI character sets as 8-bit ISO character sets, which can result in errors when converting them to Unicode. This is something to be aware of when encoding and decoding text generated by

older applications. Before the widespread adoption of UTF-8, it was particularly common for legacy Windows mail clients to default to using Windows-1252 for text and label it as using ISO 8859-1.

Although the control supports UTF-16, it is recommended you use UTF-8 instead. Text which uses UTF-16 will always be base64 encoded, and some mail clients may not recognize it as a valid character set. If the message does not specify if big endian or little endian byte order is used, the library will default to little endian. When UTF-16 is used when composing a new message, it will always use little endian byte order.

If you are using this control with Visual Basic 6.0, be aware that the IDE does not provide complete support for Unicode text. Although the control uses Unicode internally, if a header or message body contains characters which cannot be displayed using the current system ANSI code page, the text can appear to be corrupted when examining the string using the debugger. If a message contains text which uses a character set other than the system default, you must use controls which are Unicode aware to display the text, such as the Microsoft InkEdit control. The standard TextBox and other common controls in Visual Basic do not support Unicode.

[ComposeMessage Method](#), [CreatePart Method](#)

Internet Mail Control Error Codes

Value	Constant	Description
10001	mailErrorNotHandleOwner	Handle not owned by the current thread
10002	mailErrorFileNotFound	The specified file or directory does not exist
10003	mailErrorFileNotCreated	The specified file could not be created
10004	mailErrorOperationCanceled	The blocking operation has been canceled
10005	mailErrorInvalidFileType	The specified file is a block or character device, not a regular file
10006	mailErrorInvalidDevice	The specified device or address does not exist
10007	mailErrorTooManyParameters	The maximum number of function parameters has been exceeded
10008	mailErrorInvalidFileName	The specified file name contains invalid characters or is too long
10009	mailErrorInvalidFileHandle	Invalid file handle passed to function
10010	mailErrorFileReadFailed	Unable to read data from the specified file
10011	mailErrorFileWriteFailed	Unable to write data to the specified file
10012	mailErrorOutOfMemory	Out of memory
10013	mailErrorAccessDenied	Access denied
10014	mailErrorInvalidParameter	Invalid argument passed to function
10015	mailErrorClipboardUnavailable	The system clipboard is currently unavailable
10016	mailErrorClipboardEmpty	The system clipboard is empty or does not contain any text data
10017	mailErrorFileEmpty	The specified file does not contain any data
10018	mailErrorFileExists	The specified file already exists
10019	mailErrorEndOfFile	End of file
10020	mailErrorDeviceNotFound	The specified device could not be found
10021	mailErrorDirectoryNotFound	The specified directory could not be found
10022	mailErrorInvalidBuffer	Invalid memory address passed to function
10024	mailErrorNoHandles	No more handles available to this process
10035	mailErrorOperationWouldBlock	The specified operation would block the current thread
10036	mailErrorOperationInProgress	A blocking operation is currently in progress
10037	mailErrorAlreadyInProgress	The specified operation is already in progress
10038	mailErrorInvalidHandle	Invalid handle passed to function
10039	mailErrorInvalidAddress	Invalid network address specified
10040	mailErrorInvalidSize	Datagram is too large to fit in specified buffer
10041	mailErrorInvalidProtocol	Invalid network protocol specified
10042	mailErrorProtocolNotAvailable	The specified network protocol is not available
10043	mailErrorProtocolNotSupported	The specified protocol is not supported
10044	mailErrorSocketNotSupported	The specified socket type is not supported
10045	mailErrorInvalidOption	The specified option is invalid
10046	mailErrorProtocolFamily	The specified protocol family is not supported

10047	mailErrorProtocolAddress	The specified address is invalid for this protocol family
10048	mailErrorAddressInUse	The specified address is in use by another process
10049	mailErrorAddressUnavailable	The specified address cannot be assigned
10050	mailErrorNetworkUnavailable	The networking subsystem is unavailable
10051	mailErrorNetworkUnreachable	The specified network is unreachable
10052	mailErrorNetworkReset	Network dropped connection on reset
10053	mailErrorConnectionAborted	Connection was aborted due to timeout or other failure
10054	mailErrorConnectionReset	Connection was reset by remote network
10055	mailErrorOutOfBuffers	No buffer space is available
10056	mailErrorAlreadyConnected	Connection already established with server
10057	mailErrorNotConnected	No connection established with server
10058	mailErrorConnectionShutdown	Unable to send or receive data after connection shutdown
10060	mailErrorOperationTimeout	The specified operation has timed out
10061	mailErrorConnectionRefused	The connection has been refused by the server
10064	mailErrorHostUnavailable	The specified host is unavailable
10065	mailErrorHostUnreachable	The specified host is unreachable
10067	mailErrorTooManyProcesses	Too many processes are using the networking subsystem
10091	mailErrorNetworkNotReady	Network subsystem is not ready for communication
10092	mailErrorInvalidVersion	This version of the operating system is not supported
10093	mailErrorNetworkNotInitialized	The networking subsystem has not been initialized
10101	mailErrorRemoteShutdown	The server has initiated a graceful shutdown sequence
11001	mailErrorInvalidHostName	The specified hostname is invalid or could not be resolved
11002	mailErrorHostNameNotFound	The specified hostname could not be found
11003	mailErrorHostNameRefused	Unable to resolve hostname, request refused
11004	mailErrorHostNameNotResolved	Unable to resolve hostname, no address for specified host
12001	mailErrorInvalidLicense	The license for this product is invalid
12002	mailErrorProductNotLicensed	This product is not licensed to perform this operation
12003	mailErrorNotImplemented	This function has not been implemented on this platform
12004	mailErrorUnknownLocalHost	Unable to determine local host name
12005	mailErrorInvalidHostAddress	Invalid host address specified
12006	mailErrorInvalidServicePort	Invalid service port number specified
12007	mailErrorInvalidServiceName	Invalid or unknown service name specified
12008	mailErrorInvalidEventId	Invalid event identifier specified
12009	mailErrorOperationNotBlocking	No blocking operation in progress on this socket
12101	mailErrorSecurityNotInitialized	Unable to initialize security interface for this process
12102	mailErrorSecurityContext	Unable to establish security context for this session
12103	mailErrorSecurityCredentials	Unable to open client certificate store or establish client credentials
12104	mailErrorSecurityCertificate	Unable to validate the certificate chain for this session

12105	mailErrorSecurityDecryption	Unable to decrypt data stream
12106	mailErrorSecurityEncryption	Unable to encrypt data stream
12201	mailErrorOperationNotSupported	The specified operation is not supported
12202	mailErrorInvalidProtocolVersion	Invalid application protocol version specified
12203	mailErrorNoServerResponse	No data returned from server
12204	mailErrorInvalidServerResponse	Invalid data returned from server
12205	mailErrorUnexpectedServerResponse	Unexpected response code returned from server
12206	mailErrorServerTransactionFailed	Server transaction failed
12207	mailErrorServiceUnavailable	The service is currently unavailable
12208	mailErrorServiceNotReady	The service is not ready, try again later
12209	mailErrorServerResyncFailed	Unable to resynchronize with server
12210	mailErrorInvalidProxyType	Invalid proxy server type specified
12211	mailErrorProxyRequired	Resource must be accessed through specified proxy
12212	mailErrorInvalidProxyLogin	Unable to login to proxy server using specified credentials
12213	mailErrorProxyResyncFailed	Unable to resynchronize with proxy server
12214	mailErrorInvalidCommand	Invalid command specified
12215	mailErrorInvalidCommandParameter	Invalid command parameter specified
12216	mailErrorInvalidCommandSequence	Invalid command sequence specified
12217	mailErrorCommandNotImplemented	Specified command not implemented on this server
12218	mailErrorCommandNotAuthorized	Specified command not authorized for the current user
12219	mailErrorCommandAborted	Specified command was aborted by the server
12220	mailErrorOptionNotSupported	The specified option is not supported on this server
12221	mailErrorRequestNotCompleted	The current client request has not been completed
12222	mailErrorInvalidUsername	The specified username is invalid
12223	mailErrorInvalidPassword	The specified password is invalid
12224	mailErrorInvalidAccount	The specified account name is invalid
12225	mailErrorAccountRequired	Account name has not been specified
12226	mailErrorInvalidAuthenticationType	Invalid authentication protocol specified
12227	mailErrorAuthenticationRequired	User authentication is required
12228	mailErrorProxyAuthenticationRequired	Proxy authentication required
12229	mailErrorAlreadyAuthenticated	User has already been authenticated
12230	mailErrorAuthenticationFailed	Unable to authenticate the specified user
12251	mailErrorNetworkAdapter	Unable to determine network adapter configuration
12252	mailErrorInvalidRecordType	Invalid record type specified
12253	mailErrorInvalidRecordName	Invalid record name specified
12254	mailErrorInvalidRecordData	Invalid record data specified
12255	mailErrorConnectionOpen	Data connection already established
12256	mailErrorConnectionClosed	Server closed data connection

12257	mailErrorConnectionPassive	Data connection is passive
12258	mailErrorConnectionFailed	Unable to open data connection to server
12259	mailErrorInvalidSecurityLevel	Data connection cannot be opened with this security setting
12260	mailErrorCachedTlsRequired	Data connection requires cached tls session
12261	mailErrorDataReadOnly	Data connection is read-only
12262	mailErrorDataWriteOnly	Data connection is write-only
12263	mailErrorEndOfData	End of data
12264	mailErrorRemoteFileUnavailable	Remote file is unavailable
12265	mailErrorInsufficientStorage	Insufficient storage on server
12266	mailErrorStorageAllocation	File exceeded storage allocation on server
12267	mailErrorDirectoryExists	The specified directory already exists
12268	mailErrorDirectoryEmpty	No files returned by the server for the specified directory
12269	mailErrorEndOfDirectory	End of directory listing
12270	mailErrorUnknownDirectoryFormat	Unknown directory format
12271	mailErrorInvalidResource	Invalid resource name specified
12272	mailErrorResourceRedirected	The specified resource has been redirected
12273	mailErrorResourceRestricted	Access to this resource has been restricted
12274	mailErrorResourceNotModified	The specified resource has not been modified
12275	mailErrorResourceNotFound	The specified resource cannot be found
12276	mailErrorResourceConflict	Request could not be completed due to the current state of the resource
12277	mailErrorResourceRemoved	The specified resource has been permanently removed from this server
12278	mailErrorContentLengthRequired	Request must include the content length
12279	mailErrorRequestPrecondition	Request could not be completed due to server precondition
12280	mailErrorUnsupportedMediaType	Request specified an unsupported media type
12281	mailErrorInvalidContentRange	Content range specified for this resource is invalid
12282	mailErrorInvalidMessagePart	Message is not multipart or an invalid message part was specified
12283	mailErrorInvalidMessageHeader	The specified message header is invalid or has not been defined
12284	mailErrorInvalidMessageBoundary	The multipart message boundary has not been defined
12285	mailErrorNoFileAttachment	The current message part does not contain a file attachment
12286	mailErrorUnknownFileType	The specified file type could not be determined
12287	mailErrorDataNotEncoded	The specified data block could not be encoded
12288	mailErrorDataNotDecoded	The specified data block could not be decoded
12289	mailErrorFileNotEncoded	The specified file could not be encoded
12290	mailErrorFileNotDecoded	The specified file could not be decoded
12291	mailErrorNoMessageText	No message text
12292	mailErrorInvalidCharacterSet	Invalid character set specified
12293	mailErrorInvalidEncodingType	Invalid encoding type specified
12294	mailErrorInvalidMessageNumber	Invalid message number specified

12295	mailErrorNoReturnAddress	No valid return address specified
12296	mailErrorNoValidRecipients	No valid recipients specified
12297	mailErrorInvalidRecipient	The specified recipient address is invalid
12298	mailErrorRelayNotAuthorized	The specified domain is invalid or server will not relay messages
12299	mailErrorMailboxUnavailable	Specified mailbox is currently unavailable
12300	mailErrorMailboxReadOnly	The selected mailbox cannot be modified
12301	mailErrorMailboxNotSelected	No mailbox has been selected
12302	mailErrorInvalidMailbox	Specified mailbox is invalid
12303	mailErrorInvalidDomain	The specified domain name is invalid or not recognized
12304	mailErrorInvalidSender	The specified sender address is invalid or not recognized
12305	mailErrorMessageNotDelivered	Message not delivered to any of the specified recipients
12306	mailErrorEndOfMessageData	No more message data available to be read
12307	mailErrorInvalidMessageSize	The specified message size is invalid
12308	mailErrorMessageNotCreated	The message could not be created in the specified mailbox
12309	mailErrorNoMoreMailboxes	No more mailboxes exist on this server
12329	mailErrorInvalidDateFormat	The specified date format is not recognized
12330	mailErrorFeatureNotSupported	The specified feature is not supported on this server
12346	mailErrorNoMessageStore	No message store has been specified
12347	mailErrorMessageStoreChanged	The message store has changed since it was last accessed
12348	mailErrorMessageNotFound	No message was found that matches the specified criteria
12349	mailErrorMessageDeleted	The specified message has been deleted

Internet Server Control

A general purpose TCP/IP networking component for developing server applications.

- [Error Codes](#)

Control Information

Object Name	InternetServerCtl.InternetServer
File Name	CSWSVX12.OCX
Version	12.0.3024.1286
ProgID	SocketTools.InternetServer.12
ClassID	C1F0B98E-583F-45B3-9BA9-A8D6F45103DF
Threading Model	Apartment
Help File	CSW12HLP.CHM
Dependencies	None
Standards	RFC 768, RFC 791, RFC 793

Overview

The Internet Server ActiveX control provides a simplified interface for creating event-driven, multithreaded server applications using the TCP/IP protocol. The control interface is similar to the SocketWrench ActiveX control, however it is designed specifically to make it easier to implement a server application without requiring the need to manage multiple socket controls. In addition, the Internet Server control supports secure communications using the Transport Layer Security (TLS) protocol.

Each instance of the Internet Server control represents a server, and each active client connection is managed internally and referenced by an integer value which uniquely identifies the client session. All interaction with the server and the clients connected to it uses an event-driven model, with the program written to respond to events such as OnConnect, OnRead and OnWrite.

Developers who have used the SocketWrench ActiveX control will find the Internet Server control has a familiar interface, with a subset of properties and methods that are specific to creating a server application. Each of the network events have an extra parameter which specifies the socket handle which should be used when communicating with the client. This enables the application to communicate with multiple clients without having to create multiple socket objects or use a control array.

Requirements

The SocketTools ActiveX Edition components are self-registering controls that are compatible with any programming language that supports the Component Object Model (COM) and the ActiveX control specification. If you are using Visual Basic 6.0, Service Pack 6 (SP6) is required. We recommend

installing all available updates for your development tools. Although the Visual Basic 6.0 runtime is supported on Windows 11, the IDE itself is no longer officially supported by Microsoft. Legacy IDEs and compilers may also require elevated (administrator) privileges to run properly.

The ActiveX controls are supported on Windows 7, Windows Server 2008 R2, and later versions of both desktop and server editions of Windows. For Windows 7, Service Pack 1 (SP1) is the minimum requirement. For Windows 8 systems, the 8.1 update must be installed. On ARM-based platforms, the minimum supported version is Windows 10 build 1709.

SocketTools includes components for both 32-bit (x86) and 64-bit (x64) Windows platforms. All modern versions of Windows are 64-bit, but we continue to include 32-bit components for compatibility with legacy development tools such as Visual Basic 6.0. We also provide native ARM64 ActiveX controls for systems running Windows on ARM. Note that 32-bit applications on ARM run using x86 emulation, and Microsoft no longer supports native ARM32 applications.

If you are using VBScript, Visual Basic for Applications (VBA), or another scripting environment on an ARM-based system, be aware that 64-bit hosts will require ARM64 components, while 32-bit hosts will use x86 components under emulation. This includes applications created with Visual Basic 6.0. To reduce deployment complexity and avoid confusion, SocketTools does not include ARM32 ActiveX controls in its standard redistribution packages but they are available on request for legacy or specialized scenarios.

Distribution

When you distribute an application that uses this control, you can either install the file in the same folder as your application executable or as a shared component in the appropriate system folder. If you install the control in the system folder, it is important that you distribute the correct version for the target platform and it must be registered. If you install the control in the same folder as your executable, it is recommended that you use registration-free activation or COM redirection to ensure that the correct version of the control is loaded by the application.

Internet Server Control Properties

Property	Description
AdapterAddress	Returns the IP address associated with the specified network adapter
AdapterCount	Returns the number of available local and remote network adapters
Backlog	Gets and sets the number of client connections that may be queued by the server
ByteOrder	Gets and sets the byte order in which integer data will be written to and read from the socket
CertificateName	Gets and sets the common name for the server certificate
CertificatePassword	Gets and sets the password associated with the server certificate
CertificateStore	Gets and sets the name of the server certificate store or file
CertificateUser	Gets and sets the user that owns the server certificate
ClientAddress	Return the address of the current client session
ClientCount	Return the number of active client sessions connected to the server
ClientHandle	Return the socket handle associated with a specific client session
ClientHost	Return the hostname for the current client session
ClientId	Return a unique identifier for the current client session
ClientName	Gets and sets a unique string moniker that is associated with the current client session
ClientPort	Return the port number used by the current client session
ClientThread	Return the thread ID for the current client session
CodePage	Gets and sets the code page used when reading and writing text
ExternalAddress	Return the external IP address assigned to the local system
IsActive	Determine if the server has been started
IsBlocked	Determine if the control is blocked performing an operation
IsClosed	Determine if the current client connection has been closed by the remote host
IsInitialized	Determine if the control has been initialized
IsListening	Determine if the server is listening for connections
IsReadable	Return if data can be read from the current client socket without blocking
IsWritable	Return if data can be written to the current client socket without blocking
KeepAlive	Set or return if keep-alive packets are sent to connected clients
LastError	Gets and sets the last error that occurred on the control
LastErrorString	Return a description of the last error that occurred
MaxClients	Gets and sets the maximum number of clients that can connect to the server
MemoryUsage	Gets the amount of memory allocated for the server and all client sessions
NoDelay	Enable or disable the Nagle algorithm
Priority	Gets and sets the priority assigned to the server
ReuseAddress	Set or return if the server address can be reused

Secure	Set or return if client connections are encrypted using the TLS security protocol.
SecureProtocol	Gets and sets the security protocol used to establish a secure connection
ServerAddress	Gets and sets the address that will be used by the server to listen for connections
ServerHandle	Return the handle to the socket created to listen for client connections
ServerName	Return the fully qualified domain name of the local system
ServerPort	Gets and sets the port number that will be used by the server to listen for connections
ServerThread	Return the thread ID for the server
StackSize	Gets and sets the size of the stack allocated for threads created by the server
ThrowError	Enables or disables error handling by the application
Timeout	Gets and sets the amount of time until a blocking operation fails
Trace	Enable or disable socket function level tracing
TraceFile	Specify the socket function trace output file
TraceFlags	Gets and sets the socket function tracing flags
Version	Return the current version of the control

AdapterAddress Property

Returns the IP address associated with the specified network adapter.

Syntax

object.AdapterAddress(Index)

Remarks

The **AdapterAddress** property array returns the IP addresses that are associated with the local network or remote dial-up network adapters configured on the system. The **AdapterCount** property can be used to determine the number of adapters that are available.

Multihomed systems with more than one local network adapter, or a combination of local and dial-up adapters will not be listed in a specific order. An application should not make the assumption that the address returned by **AdapterAddress(0)** always refers to a local network adapter.

Note that it is possible that the **AdapterCount** property will return 0, and **AdapterAddress(0)** will return an empty string. This indicates that the system does not have a physical network adapter with an assigned IP address, and there are no dial-up networking connections currently active. If a dial-up networking connection is established at some later point, the **AdapterCount** property will change to 1, and the **AdapterAddress(0)** property will return the IP address allocated for that connection.

When using Visual Studio .NET, you must use the accessor method **get_AdapterAddress** instead of the property name, otherwise an error will be returned indicating that it not a member of the control class.

Data Type

String

See Also

[AdapterCount Property](#)

AdapterCount Property

Returns the number of available local and remote network adapters.

Syntax

object.AdapterCount

Remarks

The **AdapterCount** property returns the number of local and remote dial-up networking adapters available on the local system. This value can be used in conjunction with the **AdapterAddress** property array to enumerate the IP addresses assigned to the various network adapters.

Note that it is possible that the **AdapterCount** property will return 0, and **AdapterAddress**(0) will return an empty string. This indicates that the system does not have a physical network adapter with an assigned IP address, and there are no dial-up networking connections currently active. If a dial-up networking connection is established at some later point, the **AdapterCount** property will change to 1, and the **AdapterAddress**(0) property will return IP address allocated for that connection.

Data Type

Integer (Int32)

See Also

[AdapterAddress Property](#)

Backlog Property

Gets and sets the number of client connections that may be queued by the server.

Syntax

object.Backlog [= *backlog*]

Remarks

The **Backlog** property specifies the maximum size of the queue used to manage pending connections to the service. If the property is set to value which exceeds the maximum size for the underlying service provider, it will be silently adjusted to the nearest legal value. There is no standard way to determine what the maximum backlog value is.

This property should be set to the desired value before the **Start** method is called. The default backlog value is 5 on all Windows platforms. The Windows Server platforms support a maximum backlog value of 200.

Note that this property does not specify the total number of connections that the server application may accept. It only specifies the size of the backlog queue which is used to manage pending client connections. Once the client connection has been accepted, it is removed from the queue. Set the **MaxClients** property to specify the maximum number of clients that may connect with the server.

Data Type

Integer (Int32)

See Also

[IsListening Property](#), [MaxClients Property](#), [Start Method](#), [Throttle Method](#), [OnAccept Event](#)

ByteOrder Property

Gets and sets the byte order in which integer data will be written to and read from the socket.

Syntax

object.ByteOrder [= 0 | 1]

Remarks

The **ByteOrder** property is used to specify how 16-bit (short) integer and 32-bit (long) integer data is written to and read from the socket. The default value for this property is 0, which specifies that integers should be written in the native byte order for the local machine. A value of 1 indicates that integers should be written in network byte order.

When applications write integer values on a socket (instead of string representations of those values), they should typically be converted to network byte order before they are sent. Likewise, when an integer value is read, it should then be converted from the network byte order back to the byte order used by the local machine. The native byte order, also called the host byte order, should only be used if it can be assured that both the sender and the receiver are running on an identical or compatible machine architectures (for example, if both systems are Intel-based).

This property will affect how data is read by the **Read** method and by the **Write** method, if the Variant data that is being read or written is recognized as integer data.

Data Type

Integer (Int32)

CertificateName Property

Gets and sets the common name for the server certificate.

Syntax

object.CertificateName [= *name*]

Remarks

This property sets the common name or friendly name of the certificate that should be used when starting a secure server. If the **Secure** property is set to True, this property must be specify a valid certificate name. The certificate must have a private key associated with it, otherwise client connections will fail because the control will be unable to create a security context for the session.

Certificates may be installed and viewed on the local system using the Certificate Manager that is included with the Windows operating system. For more information, refer to the documentation for the Microsoft Management Console.

Data Type

String

See Also

[CertificateStore Property](#), [Secure Property](#)

CertificatePassword Property

Gets and sets the password associated with the server certificate.

Syntax

object.CertificatePassword [= *password*]

Remarks

This property sets the password that should be used to access a certificate in the specified certificate store. It is only required when the **CertificateStore** property specifies a file that contains a certificate and private key in PKCS #12 format.

Data Type

String

See Also

[CertificateName Property](#), [CertificateStore Property](#), [Secure Property](#)

CertificateStore Property

Gets and sets the name of the server certificate store or file.

Syntax

object.CertificateStore [= *store*]

Remarks

This property sets the name of the certificate store that contains the server certificate that should be used when starting a server with security enabled. The certificate may either be stored in the registry or in a file. If the certificate is stored in the registry, then this property should be set to one of the following predefined values:

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. If a certificate store is not specified, this is the default value that is used.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

In most cases the client certificate will be installed in the user's personal certificate store, and therefore it is not necessary to set this property value because that is the default location that will be used to search for the certificate. This property is only used if the **CertificateName** property is also set to a valid certificate name.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU" for the current user, or "HKLM" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, it will default to the certificate store for the current user.

This property may also be used to specify a file that contains the client certificate. In this case, the property should specify the full path to the file and must contain both the certificate and private key in PKCS #12 format. If the file is protected by a password, the **CertificatePassword** property must also be set to specify the password.

Data Type

String

See Also

[CertificateName Property](#), [CertificatePassword Property](#), [Secure Property](#)

CertificateUser Property

Gets and sets the user that owns the server certificate.

Syntax

object.CertificateUser [= *username*]

Remarks

This property sets the name of the user that owns the server certificate that will be used. If this property is not set, the certificate store for the current user will be used when searching for the certificate. If this property is used to specify another user, the server process must have the appropriate permission to access the registry location that contains the client certificate. On Windows Vista and later versions of the operating system, this requires that the process run with elevated privileges.

Data Type

String

See Also

[CertificateName Property](#), [CertificateStore Property](#), [Secure Property](#)

ClientAddress Property

Return the Internet address of the current client connection.

Syntax

object.ClientAddress

Remarks

The **ClientAddress** property returns the address of the current client session which has connected to the server. This property only returns a meaningful value inside an event handler such as **OnAccept** or **OnConnect**.

If this property is accessed inside an **OnAccept** event handler, it will return the address of the client that is requesting the connection. The server application may use this information to determine if it wishes to accept or reject the client connection.

Data Type

String

See Also

[ClientHost Property](#), [ClientPort Property](#), [ServerAddress Property](#), [OnAccept Event](#), [OnConnect Event](#)

ClientCount Property

Return the number of active client sessions connected to the server.

Syntax

object.ClientCount

Remarks

The **ClientCount** read-only property returns the number of active client sessions that have been established with the server.

The value returned by this property does not include clients that are in the process of terminating. For example, if the **Suspend** method is called to suspend the server and terminate all of the client connections, each client is signaled to disconnect from the server and the active client count is immediately set to zero. Once a client has been signaled to disconnect, it is no longer considered to be an active client connection even if that session does not terminate immediately. This means that you cannot use this property value to determine the number of clients in the process of disconnecting from the server or when all clients have disconnected.

To determine when all clients have disconnected from the server after the **Suspend** or **Restart** method has been called, you must implement an **OnIdle** event handler. This event occurs after the last active client session has terminated.

Data Type

Integer (Int32)

See Also

[ClientHandle Property](#), [Restart Method](#), [Suspend Method](#), [OnDisconnect Event](#), [OnIdle Event](#)

ClientHandle Property

Return the socket handle associated with a specific client session.

Syntax

object.ClientHandle(*Index*)

Remarks

The **ClientHandle** property is read-only, zero-based property array that returns the socket handle allocated for the client session specified by the *Index* parameter. An exception will be thrown if the index value exceeds the maximum number of active client sessions. To determine the number of clients that are currently connected to the server, use the **ClientCount** property.

You should always check the value of the **ClientCount** property prior to enumerating through the client connections using the **ClientHandle** property array. Never assume that a particular client session will always be found in the same position in the property array. The socket handles returned by the property array can be used in conjunction with the **Read** and **Write** methods to exchange data with a particular client session outside of an event handler.

Data Type

Integer (Int32)

See Also

[ClientHandle Property](#), [Disconnect Method](#), [FindClient Method](#), [Read Method](#), [Write Method](#), [OnConnect Event](#), [OnRead Event](#)

ClientHost Property

Return the hostname for the current client session.

Syntax

object.ClientHost

Remarks

The **ClientHost** property returns the hostname of the current client session which has established a connection with the server. This property value is only meaningful when accessed within an event handler, such as the **OnConnect** event.

Accessing this property causes the control to perform a blocking reverse DNS lookup, attempting to match the client Internet address with a hostname. Not all addresses have a reverse DNS record, in which case this property will return an empty string. It is recommended that most applications use the value of the **ClientAddress** property rather than use the **ClientHost** property to distinguish between client connections.

Data Type

String

See Also

[ClientAddress Property](#), [ClientPort Property](#), [ServerAddress Property](#), [OnAccept Event](#), [OnConnect Event](#)

ClientId Property

Return a unique identifier for the current client session.

Syntax

object.ClientId

Remarks

Each client connection that is accepted by the server is assigned a unique numeric value. This value can be used by the application to identify that client session, and is different than the socket handle allocated for the client. While it is possible for a client socket handle to be reused by the operating system, client IDs are unique throughout the life of the server session and are never duplicated.

It is important to note that the actual value of the client ID should be considered opaque. It is only guaranteed that the value will be greater than zero, and that it will be unique to the client session.

This property only returns a meaningful value when accessed from within an event handler, or a function that has been called from within an event handler.

Data Type

Integer (Int32)

See Also

[ClientAddress Property](#), [ClientHost Property](#), [ClientName Property](#), [ServerAddress Property](#), [ServerPort Property](#)

ClientName Property

Gets and sets a unique string moniker that is associated with the current client session.

Syntax

object.ClientName [= *moniker*]

Remarks

A client moniker is a string which can be used to uniquely identify a specific client session aside from its socket handle. A moniker can be assigned to the client session by setting the **ClientName** property from within a class event handler such as the **OnConnect** event.

Monikers are not case-sensitive, and they must be unique so that no client socket for a particular server can have the same moniker. The maximum length for a moniker is 127 characters.

This property only returns a meaningful value when accessed from within an event handler, or a function that has been called from within an event handler.

Data Type

String

See Also

[ClientAddress Property](#), [ClientId Property](#), [ServerAddress Property](#), [ServerPort Property](#)

ClientPort Property

Return the port number of the current client connection.

Syntax

object.ClientPort

Remarks

The **ClientPort** property returns the port number that the current client has used when establishing a connection with the server. This property value is only meaningful when accessed within an event handler such as the **OnConnect** event.

Data Type

Integer (Int32)

See Also

[ClientAddress Property](#), [ClientHost Property](#), [ServerAddress Property](#), [ServerPort Property](#)

ClientThread Property

Return the thread ID for the active client session.

Syntax

object.ClientThread

Remarks

The **ClientThread** property returns the thread ID for the current client session. Until the thread terminates, the thread identifier uniquely identifies the thread throughout the system. This property only returns a meaningful value when accessed from within an event handler, or a function that has been called from within an event handler.

The thread ID can be used with Windows API functions such as **OpenThread**. Exercise caution when using thread-related functions, interfering with the normal operation of the thread can have unexpected results. You should never use this property value to obtain a thread handle and then call the **TerminateThread** function to terminate a client session. This will prevent the thread from releasing the resources that were allocated for the session and can leave the server in an unstable state. To terminate a client session, use the **Disconnect** method.

Data Type

Integer (Int32)

See Also

[ClientId Property](#), [ServerThread Property](#)

CodePage Property

Gets and sets the code page used when reading and writing text.

Syntax

object.CodePage [= *value*]

Remarks

The **CodePage** property is an integer value which specifies how strings are encoded when data is sent or received. Any valid code page identifier may be specified. Some common values are:

Value	Description
0	Text sent and received using a string should be converted using the ANSI code page for the current locale.
1	Text sent and received using a string should be converted using the system default OEM code page. The OEM code page typically contains characters that are used by console applications and are based on character sets commonly used by MS-DOS. You should not use this code page unless you know the server is sending text which includes OEM characters.
1252	Text sent and received using a string should be converted using the Windows ANSI code page for western European languages. This code page is commonly used by legacy Windows applications for English and some other western languages. It should be noted that while this code page is similar to ISO 8859-1 character encoding, it is not identical.
28591	Text sent and received using a string should be converted using the ISO 8859-1 code page for western European languages. This code page is commonly referred to as Latin-1 and is similar to the Windows 1252 code page.
65000	Data that is sent and received using a string should be converted using UTF-7 encoding. If this code page is specified, data written to the socket will be encoded as UTF-7 encoded Unicode. All data received from the server will be converted from UTF-7. It is not recommended that you use this code page unless you know that the remote host is sending UTF-7 encoded text.
65001	Data that is sent and received using a string should be converted using UTF-8 encoding. If this code page is specified, data written to the socket will be encoded as UTF-8 encoded Unicode. All data received from the server will be converted from UTF-8 to UTF-16 Unicode. Because UTF-8 is backwards compatible with the ASCII character set, it is safe to use this encoding option when sending and receiving ASCII text.

A complete list of available [code page identifiers](#) can be found in Microsoft's documentation for the Win32 API.

All data which is exchanged over a socket is sent and received as 8-bit bytes, typically referred to as "octets" in networking terminology. However, the internal string type used by ActiveX controls are Unicode where each character is represented by 16 bits. To send and receive data using strings, these Unicode strings are converted to a stream of bytes.

By default, strings are converted to an array of bytes using the code page for the current locale, mapping the 16-bit Unicode characters to bytes. Similarly, when reading data from the socket into a

string buffer, the stream of bytes received from the remote host are converted to Unicode before they are returned to your application.

If you are exchanging text with another system and it appears to be corrupted or characters are being replaced with question marks or other symbols, it is likely the system is sending text which is using a different character encoding. Most services use UTF-8 encoding to represent non-ASCII characters and selecting the UTF-8 code page will typically resolve the issue.

Strings are only guaranteed to be safe when sending and receiving text. Using a string data type is not recommended when reading or writing binary data to a socket. If possible, you should always use a byte array as the buffer parameter for the **Read** and **Write** methods whenever you are exchanging binary data.

For backwards compatibility, the control defaults to using the code page for the current locale. This property value directly corresponds to Windows code page identifiers, and will accept any valid code page in addition to the values listed above. Setting this property to an invalid code page will result in an error.

Data Type

Integer (Int32)

See Also

[Read Method](#), [ReadLine Method](#), [Write Method](#), [WriteLine Method](#)

ExternalAddress Property

Return the external IP address for the local system.

Syntax

object.ExternalAddress

Remarks

The **ExternalAddress** property returns the IP address assigned to the router that connects the local host to the Internet. This is typically used by an application executing on a system in a local network that uses a router which performs Network Address Translation (NAT). In that network configuration, the **LocalAddress** property will only return the IP address for the local system on the LAN side of the network unless a connection has already been established to a remote host. The **ExternalAddress** property can be used to determine the IP address assigned to the router on the Internet side of the connection and can be particularly useful for servers running on a system behind a NAT router.

Using this property requires that you have an active connection to the Internet; checking the value of this property on a system that uses dial-up networking may cause the operating system to automatically connect to the Internet service provider. The control may be unable to determine the external IP address for the local host for a number of reasons, particularly if the system is behind a firewall or uses a proxy server that restricts access to external sites on the Internet. If the external address for the local host cannot be determined, the property will return an empty string.

If the control is able to obtain a valid external address for the local host, that address will be cached for sixty minutes. Because dial-up connections typically have different IP addresses assigned to them each time the system is connected to the Internet, it is recommended that this property only be used in conjunction with broadband connections using a NAT router. Checking this property value may cause the thread to block until the external IP address can be resolved.

Data Type

String

See Also

[ClientAddress Property](#), [ServerAddress Property](#)

IsActive Property

Determine if the server has been started.

Syntax

object.IsActive

Remarks

The **IsActive** property returns **True** if the server has been started using the **Start** method. If the server has not been started, the property will return **False**.

To determine if the server is accepting client connections, use the **IsListening** property. This property will only indicate if the server has been started. For example, if the server has been suspended using the **Suspend** method, this property will return a value of **True**, while the **IsListening** property will return a value of **False**.

An application should not depend on this property returning **False** immediately after the **Stop** method has been called to shutdown the server. This property will continue to return **True** until all clients have disconnected from the server and the server thread has terminated. To determine when the server has stopped, implement a handler for the **OnStop** event.

Data Type

Boolean

See Also

[IsListening Property](#), [Start Method](#), [Stop Method](#), [OnStop Event](#)

IsBlocked Property

Determine if the control is blocked performing an operation.

Syntax

object.IsBlocked

Remarks

The **IsBlocked** property returns True if the control is blocked performing an operation. If the **IsBlocked** property returns False, this means there are no blocking operations on the current thread at that time. If the property returns True, this tells you that you can't proceed with a socket operation. However, if the property returns False this does not guarantee that the next socket operation will not fail with a **swErrorOperationWouldBlock** or **swErrorOperationInProgress** error. The application should treat these errors as recoverable, and should be prepared to retry operations that result in them.

Note that this property will return True if there is *any* blocking operation being performed by the application, regardless of whether the control is responsible for the blocking operation or not.

Data Type

Boolean

See Also

[LastError Property](#)

IsClosed Property

Determine if the current client connection has been closed by the remote host.

Syntax

object.IsClosed

Remarks

The **IsClosed** property returns True if the current client connection has been closed by the remote host. The value of this property is only meaningful inside an event handler such as **OnRead**.

Data Type

Boolean

See Also

[IsReadable Property](#), [IsWritable Property](#), [OnConnect Event](#), [OnRead Event](#), [OnWrite Event](#)

IsListening Property

Determine if the server is listening for client connections.

Syntax

object.IsListening

Remarks

The **IsListening** property returns True if the server is listening for connections after the **Start** method has been called. If the server has not been started, is not yet accepting client connections or has been suspended, this property will return False.

When a server is started, the control starts a background thread which creates the listening socket and begins waiting for incoming client connections. This property will only return True once the server thread has started executing, so it may not return a value of True immediately after the **Start** method has been called. To determine the status of the server at any time, check the value of the **State** property.

Data Type

Boolean

See Also

[IsActive Property](#), [Start Method](#), [Stop Method](#)

IsLocked Property

Determine if the server has been locked using the **SyncLock** method.

This property has been deprecated and may not be included in future versions of the control.

Syntax

object.IsLocked

Remarks

The **IsLocked** property returns True if the server has been locked using the **SyncLock** method. When a server is locked, all background threads created by the server will block, waiting for the lock to be released. If this property returns a value of True, no client connections can be accepted by the server, and no network events will be generated.

The **SyncLock** method creates a critical section which prevents other threads from performing any network operation. This is useful when the program needs to update global data and wants to ensure that no network operations occur while the data is being modified. However, applications must take care to release the lock as quickly as possible. If a function locks the server, it must make sure that it releases the lock before exiting that function. Leaving the server locked across function calls or event handlers can result in the server becoming non-responsive.

Data Type

Boolean

See Also

[SyncLock Method](#)

IsReadable Property

Return if data can be read from the current client socket without blocking.

Syntax

object.IsReadable

Remarks

The **IsReadable** property returns True if data can be read from the current client socket without blocking. This property can be checked before the application attempts to read the socket, preventing an error. The value of this property is only meaningful inside an event handler such as **OnRead**.

Data Type

Boolean

See Also

[IsClosed Property](#), [IsWritable Property](#), [Peek Method](#), [Read Method](#), [OnRead Event](#)

IsWritable Property

Return if data can be written to the current client socket without blocking.

Syntax

object.IsWritable

Remarks

The **IsWritable** property returns True if data can be written to the current client socket without blocking. If the **IsWritable** property returns False, this means that the application cannot write to the socket at that time. However, if the property returns True, this does not guarantee that you will be able to write to the socket without an error. The next socket operation may result in a **swErrorOperationWouldBlock** or **swErrorOperationInProgress** error. The application should treat these errors as recoverable, and should be prepared to retry operations that result in them.

The value of this property is only meaningful inside an event handler such as **OnRead** or **OnWrite**.

Data Type

Boolean

See Also

[IsClosed Property](#), [IsReadable Property](#), [OnWrite Event](#)

KeepAlive Property

Set or return if keep-alive packets are sent to connected clients.

Syntax

object.KeepAlive [= { True | False }]

Remarks

Setting the **KeepAlive** property to a value of True indicates that packets are to be sent to connected clients when no data is being exchanged to keep the connection active.

The default interval at which these packets are sent is typically two hours and cannot be modified using the control. Consult the Windows system administration documentation for information on how to change the default keep-alive interval.

Data Type

Boolean

See Also

[NoDelay Property](#), [ReuseAddress Property](#)

LastError Property

Gets and sets the last error that occurred on the control.

Syntax

object.LastError [= *errorcode*]

Remarks

The **LastError** property can be read to determine the last error that occurred for this control. If a value is assigned to this property, it must either be zero (to clear the error) or a valid error code for the control.

Data Type

Integer (Int32)

See Also

[LastErrorString Property](#), [ThrowError Property](#), [OnError Event](#)

LastErrorString Property

Return a description of the last error that occurred.

Syntax

object.LastErrorString

Remarks

The **LastErrorString** property returns a string that contains a description of the last error that occurred.

Data Type

String

See Also

[LastError Property](#), [ThrowError Property](#), [OnError Event](#)

MaxClients Property

Gets and sets the maximum number of clients that can connect to the server.

Syntax

object.MaxClients [= *clients*]

Remarks

The **MaxClients** property specifies the maximum number of client connections that will be accepted by the server. Once the maximum number of connections has been established, the server will reject any subsequent connections until the number of active client connections drops below the specified value. A value of zero specifies that there should be no limit on the number of clients.

Changing the value of this property while a server is actively listening for connections will modify the maximum number of client connections permitted, but it will not affect connections that have already been established.

By default, there are no limits on the number of client connections or the connection rate when a server is started. Use the **Throttle** method to change the maximum number of client connections per IP address or the overall connection rate threshold for the server.

It is important to note that regardless of the maximum number of clients specified by this property, the actual number of client connections that can be managed by the server depends on the number of sockets that can be allocated from the operating system. The amount of physical memory installed on the system affects the number of connections that can be maintained because each connection allocates memory for the socket context from the non-paged memory pool.

Data Type

Integer (Int32)

See Also

[Backlog Property](#), [Timeout Property](#), [Start Method](#), [Throttle Method](#)

MemoryUsage Property

Gets the amount of memory allocated for the server and all client sessions.

Syntax

object.MemoryUsage

Remarks

This read-only property returns the amount of memory allocated by the server and all active client sessions. It enumerates all memory allocations made by the server process and client session threads, returning the total number of bytes allocated for the server process. This value reflects the amount of memory explicitly allocated by this control and does not reflect the total working set size of the process, or memory allocated by any other components or libraries.

Getting the value of this property forces the server into a locked state, and all client sessions will block while the memory usage is being calculated. Because this enumerates all heaps allocated for the server process, it can be an expensive operation, particularly when there are a large number of active clients connected to the server. Frequently checking the value of this property can significantly degrade the performance of the server. It is primarily intended for use as a debugging tool to determine if memory usage is the result of an increase in active client sessions. If the value returned by this property remains reasonably constant, but the amount of memory allocated for the process continues to grow, it could indicate a memory leak in some other area of the application.

Data Type

Double

See Also

[StackSize Property](#), [Start Method](#)

NoDelay Property

Enable or disable the Nagle algorithm.

Syntax

object.NoDelay [= { True | **False** }]

Remarks

The **NoDelay** property is used to enable or disable the Nagle algorithm, which buffers unacknowledged data and ensures that a full-size packet can be sent to the remote host. By default this property value is set to False, which enables the Nagle algorithm (in other words, the data being written may not actually be sent until it is optimal to do so). Setting this property to True disables the Nagle algorithm, minimizing the time delays between the data packets being sent.

This property should be set to True only if it is absolutely required and the implications of doing so are understood. Disabling the Nagle algorithm can have a significant negative impact on the performance of the server.

Data Type

Boolean

See Also

[KeepAlive Property](#), [ReuseAddress Property](#)

Priority Property

Gets and sets the priority assigned to the server.

Syntax

object.Priority [= *priority*]

Remarks

The **Priority** property can be used to control the processor usage, memory and network bandwidth allocated by the server for client sessions. One of the following values may be specified:

Value	Description
swPriorityBackground	This priority significantly reduces the memory, processor and network resource utilization for the server. It is typically used with lightweight services running in the background that are designed for few client connections. Each client thread will be assigned a lower scheduling priority and will be frequently forced to yield execution to other threads.
swPriorityLow	This priority lowers the overall resource utilization for the client session and meters the processor utilization for the client session. Each client thread will be assigned a lower scheduling priority and will occasionally be forced to yield execution to other threads.
swPriorityNormal	The default priority which balances resource and processor utilization. It is recommended that most applications use this priority.
swPriorityHigh	This priority increases the overall resource utilization for each client session and their threads will be given higher scheduling priority. It is not recommended that this priority be used on a system with a single processor.
swPriorityCritical	This priority can significantly increase processor, memory and network utilization. Each client thread will be given higher scheduling priority and will be more responsive to network events. It is not recommended that this priority be used on a system with a single processor.

The **swPriorityNormal** priority balances resource and network bandwidth utilization while ensuring that a single-threaded server application remains responsive to the user. Lower priorities reduce the overall resource utilization of the server at the expense of throughput.

Higher priority values increase the thread priority and processor utilization for each client session. You should only change the server priority if you understand the impact it will have on the system and have thoroughly tested your application. Configuring the server to run with a higher priority can have a negative effect on the performance of other programs running on the system.

Data Type

Integer (Int32)

See Also

ReuseAddress Property

Set or return if the local address can be reused by the server.

Syntax

`object.ReuseAddress [= { True | False } ]`

Remarks

The **ReuseAddress** property is used to determine if the local address and port number can be reused when starting a new instance of the server. Setting this property to True enables a server application to listen for connections using the specified address and port number even if they were in use recently. This is typically used to enable the server to close the listening socket and immediately reopen it without getting an error that the address is in use.

When a listening socket closed, the socket will normally go into a TIME-WAIT state where the local address and port number cannot be immediately reused. A consequence of this is that calling the **Stop** method immediately followed by the **Start** method using the same address and port number values may result in an error indicating that the specified address is already in use. By setting this property to True, that error is avoided and the listening socket can be created immediately without waiting for the TIME-WAIT period to elapse. Note that calling the **Restart** method allows the local address and port number to be reused, regardless of this property value.

If you wish to determine if a local port number is already in use by another application, set this property to false and attempt to start a server using that port number. If another application is already using that port number, an error will be generated indicating that the address is in use and the server could not be started.

Data Type

Boolean

See Also

[ServerAddress Property](#), [ServerPort Property](#), [Restart Method](#), [Start Method](#), [Stop Method](#)

Secure Property

Set or return if client connections are encrypted using the TLS protocol.

Syntax

object.**Secure** [= { True | False }]

Remarks

The **Secure** property determines if client connections are encrypted using the Transport Layer Security (TLS) protocol. The default value for this property is False, which specifies that clients will use a standard, unencrypted connection to the server. To enable secure connections, the application should set this property value to True prior to calling the **Start** method.

When secure connections are enabled, the server will accept the client connection and then wait for the client to initiate the handshake where both the client and server negotiate the various encryption options available. This process is handled automatically by the server, and all that is required is that the application specify the server certificate which should be used. This is done by setting the **CertificateName** property, and optionally the **CertificateStore** property if required.

It is recommended that the application use exception handling to catch any errors that may occur when changing the value of this property. If the control is unable to initialize the Windows security libraries, an exception will be thrown when this property value is modified.

Data Type

Boolean

See Also

[CertificateName Property](#), [CertificateStore Property](#), [SecureProtocol Property](#), [Start Method](#)

SecureProtocol Property

Gets and sets the security protocol used to accept a secure connection.

Syntax

object.SecureProtocol [= *protocol*]

Remarks

The **SecureProtocol** property can be used to specify the security protocol to be used when accepting a secure connection. By default, the control will attempt to use TLS 1.3 to establish the connection. If TLS 1.3 is not supported, TLS 1.2 will be used. The appropriate protocol is automatically selected based on the capabilities of both the client and server.

It is recommended that you only change this property value if you fully understand the implications of doing so. Assigning a value to this property will override the default and force the control to attempt to use only the protocol specified. One or more of the following values may be used:

Value	Description
stProtocolNone	No security protocol has been selected. A secure connection has not been established.
stProtocolTLS10	The TLS 1.0 protocol should be used when accepting a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
stProtocolTLS11	The TLS 1.1 protocol should be used when accepting a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
stProtocolTLS12	The TLS 1.2 protocol should be used when accepting a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
stProtocolTLS13	The TLS 1.3 protocol should be used when accepting a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

Multiple security protocols may be specified by combining them using a bitwise Or operator. Attempting to set this property after the server has been started will result in an exception being thrown. This property should only be set after setting the **Secure** property to True and before calling the **Start** method.

Data Type

Integer (Int32)

See Also

[CertificateName Property](#), [CertificateStore Property](#), [Secure Property](#), [Start Method](#)

ServerAddress Property

Gets and sets the address that will be used by the server to listen for connections.

Syntax

object.ServerAddress [= *address*]

Remarks

The **ServerAddress** property is used to specify the default address that the server will use when listening for connections. Setting this property to the value 0.0.0.0 or an empty string indicates that the server should listen for client connections using any valid network interface. If an address is specified, it must be a valid Internet address that is bound to a network adapter configured on the local system. Clients will only be able to connect to the server using that specific address.

It is common to set this property to the value 127.0.0.1 for testing purposes. It is a non-routable address that specifies the local system, and most software firewalls are configured so they do not block applications using this address.

Data Type

String

See Also

[ExternalAddress Property](#), [ServerName Property](#), [ServerPort Property](#), [Start Method](#)

ServerHandle Property

Return the handle to the socket created to listen for client connections.

Syntax

object.ServerHandle

Remarks

The **ServerHandle** read-only property returns the handle of the server socket that was created to listen for client connections. If the server has not been started, a value of -1 is returned. This property can be used in conjunction with direct calls to the Windows Sockets API.

Data Type

Integer (Int32)

See Also

[IsListening Property](#), [Start Method](#), [Stop Method](#)

ServerName Property

Return the fully qualified domain name of the local system.

Syntax

object.ServerName

Remarks

The **ServerName** read-only property returns the fully qualified domain name of the local system. This consists of the local computer name and its domain name. The actual value returned depends on the system configuration. If no domain has been specified for the system, then only the machine name will be returned.

Data Type

String

See Also

[ServerAddress Property](#), [ServerPort Property](#), [Resolve Method](#)

ServerPort Property

Gets and sets the port number that will be used by the server to listen for connections.

Syntax

object.ServerPort [= *port*]

Remarks

The **ServerPort** property is used to set the port number that server will use to listen for incoming client connections. Valid port numbers are in the range of 1 to 65535. It is recommended that most custom servers specify a port number larger than 5000 to avoid potential conflicts with standard Internet services and ephemeral ports used by client applications.

If a port number is specified that is already in use by another application, the **OnError** event will fire and the background server thread will terminate. To enable a server to be stopped and immediately restarted using the same address and port number, make sure that the **ReuseAddress** property is set to a value of True.

Data Type

Integer (Int32)

See Also

[ReuseAddress Property](#), [ServerAddress Property](#), [ServerName Property](#), [Start Method](#)

ServerThread Property

Return the thread ID for the server.

Syntax

object.ServerThread

Remarks

The **ServerThread** property returns the thread ID for the active server. Until the thread terminates, the thread identifier uniquely identifies the thread throughout the system. If there is no active server, this property will return a value of zero.

Data Type

Integer (Int32)

See Also

[ClientAddress Property](#), [ClientThread Property](#), [ServerAddress Property](#), [ServerPort Property](#)

StackSize Property

Gets and sets the size of the stack allocated for threads created by the server.

Syntax

object.**StackSize** [= *bytes*]

Remarks

The **StackSize** property returns the initial amount of memory that is committed to the stack for each thread created by the server. By default, the stack size for each thread is set to 256K. Increasing or decreasing the stack size will only affect new threads that are created by the server, it will not affect those threads that have already been created to manage active client sessions. It is recommended that most applications use the default stack size.

You should not change this value unless you understand the impact that it will have on your system and have thoroughly tested your application. Increasing the initial commit size of the stack will remove pages from the total system commit limit, and every page of memory that is reserved for stack cannot be used for any other purpose.

Data Type

Integer (Int32)

See Also

[MemoryUsage Property](#), [Start Method](#)

ThrowError Property

Enables or disables error handling by the application.

Syntax

object.ThrowError = { True | False }

Remarks

Error handling for methods can be performed using either return codes or exceptions, depending on the value of this property.

If the **ThrowError** property is set to False, methods will return a status value indicating success or failure. Applications should check the return value of each method and use the **LastError** and **LastErrorString** properties to determine the cause of any error.

If the **ThrowError** property is set to True, errors occurring within the control will be raised to the host application as ActiveX exceptions. In addition, the **OnError** event will fire. This allows applications to use language-specific exception handling mechanisms, such as Visual Basic error handling, instead of checking individual return values after each method call.

Even when the **ThrowError** property is set to True, the **LastError** and **LastErrorString** properties will still be updated with information about the most recent error.

If an error occurs while accessing a property value, an exception will be raised regardless of the value of the **ThrowError** property. However, the **OnError** event will not be fired for property access errors.

Data Type

Boolean

Example

The following example handles errors by checking the return code of a method:

```
Dim nError As Long

' The control will not raise an exception when an error occurs
Server1.ThrowError = False

' Start the server
nError = Server1.Start()

' If the method returns an error code, then display a message box
' and exit the subroutine
If nError > 0 Then
    MsgBox Server1.LastErrorString, vbExclamation
    Exit Sub
End If
```

The following example handles errors by generating an exception:

```
On Error GoTo Failed

' The control will raise an exception when an error occurs
Server1.ThrowError = True

' Start the server
Server1.Start
Exit Sub

Failed:
```

```
' If the method fails, code execution will resume at this label  
Failed:  
MsgBox Err.Description, vbExclamation  
Exit Sub
```

See Also

[LastError Property](#), [OnError Event](#)

Timeout Property

Gets and sets the amount of time until a blocking operation fails.

Syntax

object.Timeout [= *seconds*]

Remarks

Setting this property specifies the number of seconds until a blocking network operation fails and the control returns an error.

Data Type

Integer (Int32)

See Also

[LastError Property](#), [OnError Event](#), [OnTimeout Event](#)

Trace Property

Enable or disable network function level logging.

Syntax

`object.Trace [= { True | False } ]`

Remarks

The **Trace** property is used to enable or disable the logging of network function calls. When enabled, each function call is logged to a file, including the function parameters, return value and error code if applicable. This facility can be enabled and disabled at run time, and the trace log file can be specified by setting the **TraceFile** property. All function calls that are being logged are appended to the trace file, if it exists. If no log file exists when tracing is enabled, the file is created.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

Data Type

Boolean

See Also

[TraceFile Property](#), [TraceFlags Property](#)

TraceFile Property

Gets and sets the name of the file to use when logging network function calls.

Syntax

`object.TraceFile [= filename ]`

Remarks

The **TraceFile** property is used to specify the name of the file that is created when logging is enabled. If this property is set to an empty string (the default value), then a file named **SocketTools.log** is created in the current user's Documents folder. It is recommended that you always specify a complete path to the log file. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

If the file exists, the output is appended to the file, otherwise the file is created. Since logging is enabled per-process, the log file is shared by all instances of the controls being used. If you create multiple instances of the control, you only need to enable logging for a single instance. Because log files can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "0x". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxx:xxxx:xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, the control is attempting to connect to a system with the IPv4 address 192.0.0.1 on port 1234.

If the log file cannot be created, or the user does not have permission to modify an existing file, the error is silently ignored and no output will be generated.

Data Type

String

See Also

TraceFlags Property

Gets and sets the network function logging flags.

Syntax

object.TraceFlags [= *flags*]

Remarks

The **TraceFlags** property is used to specify the type of information written to the trace file when socket function tracing is enabled. The following values may be used:

Value	Description
dnsTraceInfo	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
dnsTraceError	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
dnsTraceWarning	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
dnsTraceHexDump	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
dnsTraceTruncate	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.

Since logging is enabled per-process, the trace flags are shared by all instances of the control being used. If multiple controls have tracing enabled, the **TraceFlags** property should be set to the same value for each control. Changing the trace flags for any one instance of the control will affect the logging performed for all other instances used by the application.

Warnings are generated when a non-fatal error is returned by a Windows Sockets function. For example, if data is being written through the control and an error indicating that the operation would block is returned, only a warning is logged since the application simply needs to attempt to write the data at a later time.

Data Type

Integer (Int32)

See Also

[Trace Property](#), [TraceFile Property](#)

Version Property

Return the current version of the control.

Syntax

object.**Version**

Remarks

The **Version** property returns the current version of the object. This can be used by an application for validation purposes.

Data Type

String

Internet Server Control Methods

Method	Description
Abort	Abort the specified client session, terminating its connection to the server
Broadcast	Broadcast data to all active clients connected to the server
Cancel	Cancels the current blocking network operation
Disconnect	Disconnect the specified client session from the server
FindClient	Return the socket handle for the client session with the specified moniker or client ID
Initialize	Initialize the control and validate the runtime license key
Peek	Read data from the specified client session, but do not remove it from the socket buffer
Read	Read data from the specified client session
ReadLine	Read a line of data from the specified client session, storing it in a string buffer
Reject	Reject a pending client connection
Reset	Reset the internal state of the control, stopping the server and terminating all client connections
Resolve	Resolves a host name to a host IP address
Restart	Restart the server, terminating all active client connections
Resume	Resume accepting new client connections
Start	Start listening for client connections on the specified IP address and port number
Stop	Stop listening for new client connections and terminate all client sessions
Suspend	Suspend accepting new client connections
Throttle	Limit the maximum number of client connections, connections per IP address and connection rate
Uninitialize	Uninitialize the control and release any system resources that were allocated
Write	Write data to the specified client session
WriteLine	Write a line of data to the specified client session, terminated with a carriage-return and linefeed

Abort Method

Abort the specified client session, terminating its connection to the server.

Syntax

object.Abort(Handle)

Parameters

Handle

An integer value that specifies the handle to the client session.

Return Value

A value of zero is returned if the connection was aborted successfully. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **Abort** method immediately closes the specified client socket, terminating its connection to the server. Any queued data in the socket's send and receive buffers will be discarded, and the client may terminate abnormally unless it is designed to handle aborted connections. It is not recommended that you use this method unless you understand the implications of doing so. To gracefully terminate the client connection, use the **Disconnect** method.

See Also

[Disconnect Method](#), [Stop Method](#)

Broadcast Method

Broadcast data to all active clients connected to the server.

Syntax

object.Broadcast(*Buffer*, [*Length*])

Parameters

Buffer

A buffer variable that contains the data to be written to the server. If the variable is a **String** type, then the data will be written as a string of characters. This is the most appropriate data type to use if the server expects text data that consists of printable characters. If the server is expecting binary data, it is recommended that a **Byte** array be used instead.

Length

A numeric value which specifies the number of bytes to write. Its maximum value is $2^{31}-1 = 2147483647$. If a value is specified for this argument and it is greater than the actual size of the buffer, then the **Length** argument will be ignored and the entire contents of the buffer will be written. If the argument is omitted, then the maximum number of bytes to write is determined by the size of the buffer.

Return Value

This method returns the number of clients that the data was broadcast to. A return value of -1 indicates an error condition, and the value of the **LastError** property will indicate the cause of the failure.

Remarks

The **Broadcast** method sends the data in **Buffer** to all clients connected to the server. If this method is called inside a server event handler, the message is broadcast to all clients except for the current, active client that is processing the event notification. If this method is called outside of an event handler, the data is broadcast to all connected clients.

See Also

[Read Method](#), [ReadLine Method](#), [Write Method](#), [WriteLine Method](#)

Cancel Method

Cancel a blocking socket operation.

Syntax

object.Cancel(*Handle*)

Parameters

Handle

An integer value that specifies the handle to the client session.

Return Value

None.

Remarks

The **Cancel** method cancels any blocking network operation for the specified client session. This method sets an internal flag that is periodically checked during a blocking operation, such as waiting for more data to arrive. If the client is not blocked at the time that this method is called, it will have no effect.

See Also

[Reset Method](#)

Disconnect Method

Disconnect the specified client session from the server.

Syntax

object.Disconnect(*Handle*)

Parameters

Handle

An integer value that specifies the handle to the client session.

Return Value

A value of zero is returned if the connection was terminated successfully. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

This method terminates the specified client connection, releasing the socket handle that was allocated for the session. It is only necessary to use this method if you want the server to explicitly terminate a client connection. Normally the client will close its connection to the server, the **OnDisconnect** event will fire and the server will automatically close the socket handle allocated for that client session.

See Also

[Restart Method](#), [Stop Method](#)

FindClient Method

Return the socket handle for the client session with the specified moniker or client ID.

Syntax

object.FindClient(*Client*)

Parameters

Client

An integer value that specifies the handle to the client session or a string value that specifies a client name.

Return Value

An integer value which specifies the socket handle for the client session. If the specified moniker does not match an active client session, the method will return a value of -1 and the value of the **LastError** property will indicate the cause of the failure.

Remarks

The **FindClient** method returns a handle to the client session identified either by its moniker or client ID. The handle value that is returned can be used in conjunction with other methods that require it, such as the **Read** and **Write** methods.

If the *Client* parameter is a string, it is considered to be a client moniker and the method will search the table of connected clients and return the handle for the session that matches the specified moniker. A moniker can be assigned to the client session by setting the **ClientName** property from within an event handler such as the **OnConnect** event. Monikers are not case-sensitive, and they must be unique so that no client socket for a particular server can have the same moniker. The maximum length for a moniker is 127 characters.

If the *Client* parameter is an integer, it is considered to be a client ID and the method will return the handle for the client session that matches that ID. The ID for a client session can be obtained using the **ClientId** property from within an event handler such as the **OnConnect** event. Each client connection that is accepted by the server is assigned a unique numeric value, and unlike the socket handle for the client session, a client ID will not be reused throughout the life of the server.

See Also

[ClientCount Property](#), [ClientHandle Property](#), [ClientId Property](#), [ClientName Property](#)

Initialize Method

Initialize the control and validate the runtime license key.

Syntax

```
object.Initialize( [LicenseKey] )
```

Parameters

LicenseKey

An optional string value which specifies a runtime license key used to initialize the control. If the license key is omitted or passed as an empty string, a development license must be installed on the local system.

Return Value

A value of zero is returned if the control was initialized successfully. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

This method dynamically loads other system libraries and allocates thread local storage. In most cases, it is not necessary to call this method directly because it is automatically invoked when an instance of the control is created by the container. However, if the control is created dynamically using **CreateObject** or a similar method, this must be the first method that is called before you attempt to modify any property values or invoke other methods. Failure to initialize the control may result in subsequent errors and/or cause an exception to be raised.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the control will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the control was created.

If the control is being used within another DLL, it is important that you do not attempt to create an instance of the control or call the **Initialize** method from within the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is written in C++ and it is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for any static and global C++ objects and has the same restrictions.

Example

```
Set objServer = CreateObject("SocketTools.InternetServer.11")

nError = objServer.Initialize(strLicenseKey)
If nError > 0 Then
    MsgBox "Unable to initialize the InternetServer control"
End
End If
```

See Also

[IsInitialized Property](#), [Uninitialize Method](#)

Peek Method

Return data read from the specified client session, but do not remove it from the socket buffer.

Syntax

object.Peek(Handle, Buffer, [Length])

Parameters

Handle

An integer value that specifies the handle to the client session.

Buffer

A buffer that the data will be stored in. If the variable is a **String** then the data will be returned as a string of characters. This is the most appropriate data type to use if the server is sending data that consists of printable characters. If the server is sending binary data, it is recommended that a **Byte** array be used instead. This parameter must be passed by reference.

Length

A numeric value which specifies the number of bytes to read. Its maximum value is $2^{31}-1 = 2147483647$. This argument is required to be present for string data. If a value is specified for this argument for other permissible types of data, and it is less than number of bytes that is determined by the control, then **Length** will override the internally computed value. If the argument is omitted, then the maximum number of bytes to read is determined by the size of the buffer.

Return Value

If the method succeeds, it will return the number of bytes available to read from the socket without causing the thread to block. A return value of zero indicates that there is no data available to read at that time. If an error occurs, a value of -1 is returned.

Remarks

The **Peek** method reads the specified number of bytes from the specified socket and copies them into the buffer, but it does not remove the data from the internal socket buffer. Note that it is possible for the returned data to contain embedded null characters.

The data returned by the **Peek** method is not removed from the socket buffers. It must be consumed by a subsequent call to the **Read** method. The return value indicates the number of bytes that can be read in a single operation, up to the specified buffer size. However, it is important to note that it may not indicate the total amount of data available to be read from the socket at that time.

If no data is available to be read, the method will return a value of zero. Using this method in a loop to poll a socket may cause the server application to become non-responsive. To determine if there is data available to be read, use the **IsReadable** property.

See Also

[IsReadable Property](#), [Read Method](#), [ReadLine Method](#), [Write Method](#), [WriteLine Method](#), [OnRead Event](#), [OnWrite Event](#)

Read Method

Return data read from the specified client session.

Syntax

object.Read(Handle, Buffer, [Length])

Parameters

Handle

An integer value that specifies the handle to the client session.

Buffer

A buffer that the data will be stored in. If the variable is a **String** then the data will be returned as a string of characters. This is the most appropriate data type to use if the server is sending data that consists of printable characters. If the server is sending binary data, a **Byte** array should be used instead. This parameter must be passed by reference.

Length

A numeric value which specifies the number of bytes to read. Its maximum value is $2^{31}-1 = 2147483647$. This argument is required to be present for string data. If a value is specified for this argument for other permissible types of data, and it is less than number of bytes that is determined by the control, then **Length** will override the internally computed value. If the argument is omitted, then the maximum number of bytes to read is determined by the size of the buffer.

Return Value

The number of bytes actually read from the socket is returned by this method. If an error occurs, a value of -1 is returned.

Remarks

The **Read** method returns data that has been sent by the client to the server, up to the number of bytes specified. If no data is available to be read, the application will wait until data is returned by the server or the client connection is closed.

If the data contains binary characters, particularly non-printable control characters and embedded nulls, you should always provide a **Byte** array to the **Read** method. When you provide a **String** variable as the buffer, the control will process the data as text. Binary characters may be interpreted as 8-bit ANSI character encoding and embedded null characters will corrupt the data. Reading the data into a byte array ensures that you receive the data exactly as it was sent by the server.

See Also

[CodePage Property](#), [IsReadable Property](#), [Peek Method](#), [ReadLine Method](#), [Write Method](#), [OnRead Event](#), [OnWrite Event](#)

ReadLine Method

Read up to a line of data from the socket and returns it in a string buffer.

Syntax

object.ReadLine(*Handle*, *Buffer*, [*Length*])

Parameters

Handle

An integer value that specifies the handle to the client session.

Buffer

A buffer that the data will be stored in. If the variable is a String then the data will be returned as a string of characters. This is the most appropriate data type to use if the server is sending data that consists of printable characters. If the server is sending binary data, it is recommended that a Byte array be used instead. This parameter must be passed by reference.

Length

A numeric value which specifies the number of bytes to read. Its maximum value is $2^{31}-1 = 2147483647$. This argument is required to be present for string data. If a value is specified for this argument for other permissible types of data, and it is less than number of bytes that is determined by the control, then **Length** will override the internally computed value. If the argument is omitted, then the maximum number of bytes to read is determined by the size of the buffer.

Return Value

This method will return True if a line of data has been read. If an error occurs or there is no more data available to read, then the method will return False. It is possible for data to be returned in the string buffer even if the return value is False. Applications should check the length of the string after the method returns to determine if any data was copied into the buffer. For example, if a timeout occurs while the method is waiting for more data to arrive on the socket, it will return zero; however, data may have already been copied into the string buffer prior to the error condition. It is the responsibility of the application to process that data, regardless of the function return value.

Remarks

The **ReadLine** method reads data from the socket up to the specified number of bytes or until an end-of-line character sequence is encountered. Unlike the **Read** method which reads arbitrary bytes of data, this function is specifically designed to return a single line of text data in a string variable. When an end-of-line character sequence is encountered, the function will stop and return the data up to that point; the string will not contain the carriage-return or linefeed characters.

There are some limitations when using the **ReadLine** method. The method should only be used to read text, never binary data. In particular, it will discard nulls, linefeed and carriage return control characters. This method will force the thread to block until an end-of-line character sequence is processed, the read operation times out or the remote host closes its end of the socket connection.

The **Read** and **ReadLine** methods can be intermixed, however be aware that the **Read** method will consume any data that has already been buffered by the **ReadLine** method and this may have unexpected results.

See Also

[CodePage Property](#), [IsReadable Property](#), [Peek Method](#), [Read Method](#), [Write Method](#), [WriteLine](#)

Reject Method

Rejects a connection request from a remote host.

Syntax

object.Reject

Parameters

None.

Return Value

A value of zero is returned if the rejection was successful. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **Reject** method rejects a pending client connection and the remote host will see this as the connection being aborted. If there are no pending client connections at the time, this method will immediately return with an error indicating that the operation would cause the thread to block.

This method can only be used inside the **OnAccept** event, when the server accepts the pending client connection. If this method is called outside of an event handler, it will fail.

Rejecting a client connection can cause the client to terminate abnormally unless it is designed to handle aborted connection attempts. It is not recommended that you use this method unless you understand the implications of doing so. To gracefully terminate a client connection, use the **Disconnect** method.

See Also

[Abort Method](#), [Disconnect Method](#), [Start Method](#), [OnAccept Event](#)

Reset Method

Reset the internal state of the control, stopping the server and terminating all client connections.

Syntax

object.Reset

Parameters

None.

Return Value

None.

Remarks

The **Reset** method resets the internal state of the control. Property values are initialized to their internal defaults, open network connections will be closed and any handles allocated by the control will be released. If the server is active when this method is called, the method will return immediately and the server shutdown process will proceed asynchronously in the background.

If this method is used to forcibly stop an active server, no further events will be generated by the control. The **OnDisconnect** event will not fire for each client session that is terminated and the **OnStop** event will not fire when the shutdown process has completed. If your application depends on these events, you should not use the **Reset** method to stop an active server.

See Also

[Restart Method](#), [Stop Method](#), [OnStop Event](#)

Resolve Method

Resolves a host name to a host IP address.

Syntax

object.Resolve(HostName, IpAddress)

Parameters

HostName

A string value that specifies the host name to resolve.

IpAddress

A string that will contain the IP address for the specified host name when the method returns. This parameter must be passed by reference.

Return Value

A value of zero is returned if the host name could be resolved into an IP address. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

See Also

[ClientAddress Property](#), [ClientHost Property](#), [ServerAddress Property](#), [ServerName Property](#)

Restart Method

Restart the server, terminating all active client connections

Syntax

object.Restart

Parameters

None.

Return Value

A value of zero is returned if the operation was successful, otherwise a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **Restart** method terminates all active client connections, recreates a new listening socket bound to the same address and port number, and then resumes accepting new client connections.

See Also

[IsActive Property](#), [IsListening Property](#), [ReuseAddress Property](#), [Start Method](#), [Stop Method](#),

Resume Method

Resume accepting new client connections.

Syntax

object.Restart

Parameters

None.

Return Value

A value of zero is returned if the operation was successful, otherwise a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **Resume** method instructs the server to resume accepting new client connections. Any pending client connections that were requested while the server was suspended will be accepted.

See Also

[IsActive Property](#), [IsListening Property](#), [Restart Method](#), [Start Method](#), [Stop Method](#), [Suspend Method](#)

Start Method

Start listening for client connections on the specified IP address and port number.

Syntax

object.Start([LocalAddress], [LocalPort], [Backlog], [MaxClients], [Timeout], [Options])

Parameters

LocalAddress

An optional string value that specifies the IP address of the network adapter that the control should use when listening for connection requests. If this is an empty string, the server will listen for connection on all valid network interfaces configured for the local system. If this argument is not specified, the control will accept connections on the address specified by the value of the **ServerAddress** property.

LocalPort

An optional integer value that specifies the port number to listen for connections on. If this argument is not provided, it defaults to the value specified by the **ServerPort** property.

Backlog

An optional integer value that specifies the maximum size of the queue used to manage pending connections to the service. If the argument is set to value which exceeds the maximum size for the underlying service provider, it will be silently adjusted to the nearest legal value. On Windows workstations, the maximum backlog value is 5. On Windows servers, the maximum value is 200. If this argument is not provided, the value specified by the **Backlog** property will be used.

MaxClients

An optional integer value that specifies the maximum number of clients that may connect to the server. If this argument is not provided, the value specified by the **MaxClients** property will be used. A value of zero specifies that there is no fixed limit to the number of active client connections that may be established with the server. This value can be adjusted after the server has been created by calling the **Throttle** method

Timeout

An optional integer value that specifies the number of seconds the control will wait for a network operation to complete. If this argument is not specified, the value of the **Timeout** property will be used as the default

Options

An optional integer value that specifies specifies one or more socket options which are to be used when establishing the connection. The value is created by combining the options using a bitwise Or operator. Note that if this argument is specified, it will override any property values that are related to that option.

Value	Description
swOptionDontRoute	This option specifies default routing should not be used. This option should not be specified unless absolutely necessary.
swOptionKeepAlive	This option specifies that packets are to be sent to the remote system when no data is being exchanged to keep the connection active. This is the same as setting the KeepAlive property to a value of True.

swOptionReuseAddress	This option specifies the local address can be reused when the server is stopped and immediately restarted. This is the same as setting the ReuseAddress property to a value of True.
swOptionNoDelay	This option disables the Nagle algorithm, which buffers unacknowledged data and insures that a full-size packet can be sent to the remote host. This is the same as setting the NoDelay property to a value of True.
swOptionSecure	This option specifies the server will enable the security protocols and negotiate with the client to establish an encrypted session. This is the same as setting the Secure property to a value of True.< </td>

Return Value

A value of zero is returned if the operation was successful, otherwise a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **Start** method begins listening for client connections on the specified local address and port number. The server is started in its own thread and manages the client sessions independently of the calling thread.

To listen for connections on any suitable IPv4 interface, specify the special dotted-quad address "0.0.0.0". You can accept connections from clients using either IPv4 or IPv6 on the same socket by specifying the special IPv6 address "::0", however this is only supported on Windows 7 and Windows Server 2008 R2 or later platforms. If no local address is specified, then the server will only listen for connections from clients using IPv4. This behavior is by design for backwards compatibility with systems that do not have an IPv6 TCP/IP stack installed.

See Also

[MaxClients Property](#), [ServerAddress Property](#), [ServerPort Property](#), [Timeout Property](#), [Restart Method](#), [Stop Method](#), [OnStart Event](#)

Stop Method

Stop listening for new client connections and terminate all client sessions.

Syntax

object.Stop

Parameters

None.

Return Value

A value of zero is returned if the operation was successful, otherwise a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **Stop** method instructs the server to stop accepting client connections, disconnects all active client connections and terminates the thread that is managing the server session. This method will block waiting for the clients to disconnect and the server thread to terminate. Once the server has stopped, the **OnStop** event will fire.

Clients that are disconnected using the **Stop** method are terminated immediately and will not generate an **OnDisconnect** event. If your application is using this event to perform some cleanup on a per-client basis, then you should shutdown the server by first calling the **Suspend** method to prevent new connections from being accepted and terminate all active client sessions. The **OnDisconnect** event will fire for each client as it disconnects from the server, and when the last client has disconnected, the **OnIdle** event will fire. You can then call the **Stop** method to complete the shutdown of the server.

After the server has been stopped, the closed listening socket will go into a TIME-WAIT state which prevents an application from reusing the same address and port number bound to that socket for a brief period of time, typically two to four minutes. This is normal behavior designed to prevent delayed or misrouted packets of data from being read by a subsequent connection. To immediately start a new server using the same local address and port number, set the **ReuseAddress** property to a value of True.

See Also

[IsActive Property](#), [Restart Method](#), [Start Method](#), [Suspend Method](#), [OnStop Event](#)

Suspend Method

Suspend accepting new client connections.

Syntax

object.Suspend

Parameters

None.

Return Value

A value of zero is returned if the operation was successful, otherwise a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **Suspend** method instructs the server to suspend accepting new client connections. Any incoming client connections will be queued up to the maximum backlog value specified when the server was started. To resume accepting client connections, call the **Resume** method.

It is not recommended that you leave a server in a suspended state for extended periods of time. Once the connection backlog queue has filled, subsequent incoming client connections will be rejected.

See Also

[IsActive Property](#), [IsListening Property](#), [Restart Method](#), [Resume Method](#), [Start Method](#), [Stop Method](#)

Throttle Method

Limit the maximum number of client connections, connections per IP address and connection rate.

Syntax

object.**Throttle**([*MaxClients*], [*MaxClientsPerAddress*], [*ConnectionRate*])

Parameters

MaxClients

An optional integer value that specifies the maximum number of clients that may connect to the server. A value of zero specifies that there is no fixed limit to the number of client connections.

MaxClientsPerAddress

An optional integer value that specifies the maximum number of clients that may connect to the server from the same IP address. A value of zero specifies that there is no fixed limit to the number of client connections per address. By default, there is no limit on the number of client connections per address.

ConnectionRate

An optional integer value that specifies a restriction on the rate of client connections, limiting the number of connections that will be accepted within that period of time. A value of zero specifies that there is no restriction on the rate of client connections. The higher this value, the fewer the number of connections that will be accepted within a specific period of time. By default, there is no limit on the client connection rate.

Return Value

A value of zero is returned if the operation was successful, otherwise a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **Throttle** method limits the number of connections and the connection rate to minimize the potential impact of a large number of client connections over a short period of time. This can be used to protect the server from a client application that is malfunctioning or a deliberate denial-of-service attack in which the attacker attempts to flood the server with connection attempts.

If the maximum number of client connections or maximum number of connections per address is exceeded, the server will reject subsequent connection attempts until the number of active client sessions drops below the specified threshold. Note that adjusting these values lower than the current connection limits will not affect clients that have already connected to the server. For example, if the **Start** method is called with the maximum number of clients set to 100, and then the **Throttle** method is called lowering that value to 75, no existing client connections will be affected by the change. However, the server will not accept any new connections until the number of active clients drops below 75.

Increasing the *ConnectionRate* value will force the server to slow down the rate at which it will accept incoming client connection requests. For example, setting this parameter to a value of 1000 would limit the server to accepting one client connection every second, while a value of 250 would allow the server to accept four client connections per second. Note that significantly increasing the amount of time the server must wait to accept client connections can exceed the connection backlog queue, resulting in client connections being rejected.

See Also

[MaxClients Property](#), [Timeout Property](#), [Start Method](#), [Stop Method](#),

Uninitialize Method

Uninitialize the control and release any system resources that were allocated.

Syntax

object.Uninitialize

Parameters

None.

Return Value

None.

Remarks

The **Uninitialize** method terminates any connection established by the control and resets the internal state of the control. Any active client sessions will be terminated and the server will stop listening for new client connections. Any items in the server FIFO queue will be removed and the memory allocated for the queue will be released. This method is not typically used because any resources that have been allocated by an instance of the control will automatically be released when it is destroyed.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the control will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the control was created. An application should only call the **Uninitialize** method if it has explicitly called the **Initialize** method.

See Also

[Initialize Method](#)

Write Method

Write data to the specified client session.

Syntax

object.Write(*Handle*, *Buffer*, [*Length*])

Parameters

Handle

An integer value that specifies the handle to the client session.

Buffer

A buffer variable that contains the data to be written to the server. If the variable is a **String** type, then the data will be written as a string of characters. This is the most appropriate data type to use if the server expects text data that consists of printable characters. If the server is expecting binary data, it is recommended that a **Byte** array be used instead.

Length

A numeric value which specifies the number of bytes to write. Its maximum value is $2^{31}-1 = 2147483647$. If a value is specified for this argument and it is greater than the actual size of the buffer, then the **Length** argument will be ignored and the entire contents of the buffer will be written. If the argument is omitted, then the maximum number of bytes to write is determined by the size of the buffer.

Return Value

This method returns the number of bytes actually written to the socket, or -1 if an error was encountered.

Remarks

The **Write** method sends the data in **Buffer** to the specified client socket. Typically the data is copied to an internal buffer and control is immediately returned to the calling thread. If the buffer is full, the current thread will block until the data can be sent. If the client does not acknowledge the data that is being sent to it, this method will eventually fail with an error indicating that the connection has been aborted.

If the data contains binary characters, particularly non-printable control characters and embedded nulls, you should always provide a **Byte** array to the **Write** method. When you provide a **String** variable as the buffer, the control will process the data as text. If the string contains Unicode characters, it will automatically be converted to 8-bit encoded text prior to being written. Using a byte array ensures that binary data will be sent as-is without being encoded.

See Also

[CodePage Property](#), [IsWritable Property](#), [Timeout Property](#), [Read Method](#), [Write Method](#), [OnWrite Event](#)

WriteLine Method

Write a line of data to the specified client session, terminated with a carriage-return and linefeed.

Syntax

object.WriteLine(*Handle*, [*Buffer*])

Parameters

Handle

An integer value that specifies the handle to the client session.

Buffer

An optional string which contains the data that will be sent to the remote host. The data will always be terminated with a carriage-return and linefeed control character sequence. If this argument is omitted, then a only a carriage-return and linefeed are written to the socket. Note that if the string contains a null character, any data that follows the null character will be discarded.

Return Value

This method returns True if the contents of the string have been written to the socket. If an error occurs, the method will return False.

Remarks

The **WriteLine** method writes a line of text to the remote host and terminates the line with a carriage-return and linefeed control character sequence. Unlike the **Write** method which writes arbitrary bytes of data to the socket, this method is specifically designed to write a single line of text data from a string.

The **WriteLine** method should only be used to send text, never binary data. In particular, the method will discard any data that follows a null character and will append linefeed and carriage return control characters to the data stream. Calling this this method will force the thread to block until the complete line of text has been written, the write operation times out or the remote host aborts the connection.

The **Write** and **WriteLine** function calls can be safely intermixed.

Internet Server Control Events

Event	Description
OnAccept	This event occurs when a client connects to the server
OnCancel	This event occurs when a blocking network operation is canceled
OnConnect	This event occurs when a client connection is established
OnDisconnect	This event occurs when a client connection is terminated
OnError	This event occurs when an error occurs
OnIdle	This event occurs after the last client has disconnected from the server
OnRead	This event occurs when a client has sent data to the server
OnStart	This event occurs when the server has started listening for connections
OnStop	This event occurs when the server has stopped
OnTimeout	This event occurs when a network operation times out
OnWrite	This event occurs when data can be written to the client

OnAccept Event

The **OnAccept** event is generated when a remote host connects to the server.

Syntax

Sub *object_OnAccept* ([*Index As Integer*,] **ByVal** *Handle As Variant*)

Remarks

This event occurs when a client attempts to establish a connection with the server.

The **Handle** argument specifies the socket descriptor of the server that has accepted the connection.

The **ClientAddress** property may be used to determine the IP address of the client. To prevent the client from completing the connection, call the **Reject** method.

After the client connection has been established and the worker thread for that client session has started, the **OnConnect** event will fire.

See Also

[ClientAddress Property](#), [Reject Method](#), [OnConnect Event](#)

OnCancel Event

The **OnCancel** event is generated when a blocking operation is canceled.

Syntax

Sub *object_OnCancel* ([*Index As Integer*,] **ByVal** *Handle As Variant*)

Remarks

This event occurs when a blocking operation on the socket, such as sending or receiving data, is canceled with the **Cancel** method. The *Handle* argument specifies the handle to the active client socket.

See Also

[Cancel Method](#), [OnError Event](#)

OnConnect Event

The **OnConnect** event is generated when a client connection is established.

Syntax

Sub *object_OnConnect* ([*Index As Integer*,] **ByVal** *Handle As Variant*)

Remarks

The **OnConnect** event is generated when the client connection to the server has completed. The **Handle** argument specifies the handle to the client socket that was allocated for the session. This handle can be used with methods such as **Read** and **Write** to exchange information with the client.

The **ClientAddress** property can be used to determine the IP address of the client which established the connection. To terminate the client connection, use the **Disconnect** method.

See Also

[ClientAddress Property](#), [Disconnect Method](#), [Read Method](#), [ReadLine Method](#), [Write Method](#), [WriteLine Method](#), [OnAccept Event](#), [OnDisconnect Event](#)

OnDisconnect Event

The **OnDisconnect** event is generated when a client connection is terminated.

Syntax

Sub *object_OnDisconnect* ([*Index As Integer*,] *ByVal Handle As Variant*)

Remarks

The **OnDisconnect** event is generated when the connection is terminated by the client and there is no more data available to be read. The ***Handle*** argument specifies the socket handle of the client session which has terminated. It is important to note that the client handle is provided for informational purposes only and the application should not attempt to read or write data using this handle. When this event fires, the connection to the client has already been closed and the handle is no longer valid.

It is not necessary to call the **Disconnect** method inside the **OnDisconnect** event handler because the connection has already been closed.

See Also

[OnConnect Event](#)

OnError Event

The **OnError** event is generated when a control error occurs.

Syntax

```
Sub object_OnError ( [Index As Integer,] ByVal Handle As Variant, ByVal ErrorCode As Variant,  
ByVal Description As Variant )
```

Remarks

This event occurs when an error occurs during a control action. Visual Basic errors do not generate this event.

The ***Handle*** argument specifies the handle to the server or the specific client session which is associated with the error.

The ***ErrorCode*** argument specifies the last error that has occurred. If the error is network related, the error code values returned by the control correspond to those returned by the standard Windows Sockets library.

The ***Description*** argument is a string that describes the error.

See Also

[LastError Property](#), [LastErrorString Property](#), [ThrowError Property](#)

OnIdle Event

The **OnIdle** event is generated after the last client has disconnected from the server.

Syntax

Sub *object_OnIdle* ([*Index As Integer*])

Remarks

This event will only occur after at least one client has connected to the server and then closes its connection or is disconnected. This event will not occur immediately after the server has started using the **Start** method, and will not occur when the server is stopped using the **Stop** method. Your application should implement an **OnStart** event handler for when the server first starts, and an **OnStop** event handler for when the server is stopped.

If one or more new client connections are accepted after this event occurs, the event will be generated again when those clients disconnect and the active client count drops to zero. Therefore it is to be expected that this event will occur multiple times over the lifetime of the server as it continues to listen for connections.

See Also

[IsActive Property](#), [Restart Method](#), [Start Method](#), [Stop Method](#), [OnStop Event](#)

OnRead Event

The **OnRead** event is generated when a client has sent data to the server.

Syntax

Sub *object_OnRead* ([*Index As Integer*,] *ByVal Handle As Variant*)

Remarks

The **OnRead** event is generated when the client sends data to the server. The *Handle* argument specifies the handle to the client socket which can be used with the **Read** or **ReadLine** methods to read the data that was sent.

The application should not call the **Read** method repeatedly inside the **OnRead** event handler. When this event fires, it guarantees that data can be read from the specified client without causing the program to enter a blocked state. However, calling this method multiple times inside the event handler may cause the application to block when there is no more data available to read and this can negatively impact the overall performance of the server.

The preferred approach is to call the **Read** method once inside the event handler, buffer and/or process the data received from the client and exit the event handler. If there is more data available to be read from the client, the **OnRead** event will fire again. If you must call the **Read** method multiple times within the event handler, first check the value of the **IsReadable** property to determine if there is data available to be read.

See Also

[IsReadable Property](#), [Peek Method](#), [Read Method](#), [Write Method](#), [OnWrite Event](#)

OnStart Event

The **OnStart** event is generated when the server starts listening for connections.

Syntax

Sub *object_OnStart* ([*Index As Integer*])

Remarks

This event occurs after the **Start** method has been called and the server and begins listening for connections from clients. An application can use this event to update the user interface and perform any additional initialization functions that are required by the application.

See Also

[IsActive Property](#), [Start Method](#), [Stop Method](#), [OnStop Event](#)

OnStop Event

The **OnStop** event is generated when the server has stopped.

Syntax

Sub *object_OnStop* ([*Index As Integer*])

Remarks

This event occurs after the **Stop** method has been called and all active client sessions have terminated. An application can use this event to update the user interface and perform any additional cleanup functions that are required by the application. If the server has a large number of active clients, this event may not occur immediately. The **OnDisconnect** event will fire for each client as the server is in the process of shutting down. During the shutdown process, the server is still considered to be active, however it will not accept any further connections. When the **OnStop** event is fired, the server thread has terminated and the listening socket has been closed.

This event will not occur if the server is forcibly stopped using the **Reset** method, or when the **Uninitialize** method is called prior to disposing an instance of the control. Applications that depend on this event should ensure that the server is shutdown gracefully using the **Stop** method prior to terminating the application.

See Also

[IsActive Property](#), [Start Method](#), [Stop Method](#), [OnDisconnect Event](#), [OnStart Event](#)

OnTimeout Event

The **OnTimeout** event is fired when a network operation times out.

Syntax

Sub *object_OnTimeout* ([*Index As Integer*,] **ByVal** *Handle As Variant*)

Remarks

The **OnTimeout** event is generated when a network operation, such as sending or receiving data, times out. The **Handle** property specifies the socket handle for the current client session when the timeout occurred.

The value of the **Timeout** property determines how long the control will wait for a network operation to complete.

See Also

[Timeout Property](#), [OnCancel Event](#)

OnWrite Event

The **OnWrite** event is generated when data can be written to the client.

Syntax

Sub *object_OnWrite* ([*Index As Integer*,] **ByVal** *Handle As Variant*)

Remarks

The **OnWrite** event is generated when the client can accept data from the server. The *Handle* argument specifies the handle to the client socket and can be used in conjunction with the **Write** or **WriteLine** methods.

This event is typically fired once when the client connection is established with the server, the session thread starts and the client socket enters a writable state. If the internal send buffer for the client socket becomes full, this event will fire again when more data can be written to the socket. It is important to note that this event is level-triggered and will not fire repeatedly if the client socket is writable. Under most circumstances this event fire only once for each client session after the initial connection has been established.

Internet Server Control Error Codes

Value	Constant	Description
10001	swErrorNotHandleOwner	Handle not owned by the current thread
10002	swErrorFileNotFound	The specified file or directory does not exist
10003	swErrorFileNotCreated	The specified file could not be created
10004	swErrorOperationCanceled	The blocking operation has been canceled
10005	swErrorInvalidFileType	The specified file is a block or character device, not a regular file
10006	swErrorInvalidDevice	The specified device or address does not exist
10007	swErrorTooManyParameters	The maximum number of function parameters has been exceeded
10008	swErrorInvalidFileName	The specified file name contains invalid characters or is too long
10009	swErrorInvalidFileHandle	Invalid file handle passed to function
10010	swErrorFileReadFailed	Unable to read data from the specified file
10011	swErrorFileWriteFailed	Unable to write data to the specified file
10012	swErrorOutOfMemory	Out of memory
10013	swErrorAccessDenied	Access denied
10014	swErrorInvalidParameter	Invalid argument passed to function
10015	swErrorClipboardUnavailable	The system clipboard is currently unavailable
10016	swErrorClipboardEmpty	The system clipboard is empty or does not contain any text data
10017	swErrorFileEmpty	The specified file does not contain any data
10018	swErrorFileExists	The specified file already exists
10019	swErrorEndOfFile	End of file
10020	swErrorDeviceNotFound	The specified device could not be found
10021	swErrorDirectoryNotFound	The specified directory could not be found
10022	swErrorInvalidBuffer	Invalid memory address passed to function
10024	swErrorNoHandles	No more handles available to this process
10035	swErrorOperationWouldBlock	The specified operation would block the current thread
10036	swErrorOperationInProgress	A blocking operation is currently in progress
10037	swErrorAlreadyInProgress	The specified operation is already in progress
10038	swErrorInvalidHandle	Invalid handle passed to function
10039	swErrorInvalidAddress	Invalid network address specified
10040	swErrorInvalidSize	Datagram is too large to fit in specified buffer
10041	swErrorInvalidProtocol	Invalid network protocol specified
10042	swErrorProtocolNotAvailable	The specified network protocol is not available
10043	swErrorProtocolNotSupported	The specified protocol is not supported

10044	swErrorSocketNotSupported	The specified socket type is not supported
10045	swErrorInvalidOption	The specified option is invalid
10046	swErrorProtocolFamily	The specified protocol family is not supported
10047	swErrorProtocolAddress	The specified address is invalid for this protocol family
10048	swErrorAddressInUse	The specified address is in use by another process
10049	swErrorAddressUnavailable	The specified address cannot be assigned
10050	swErrorNetworkUnavailable	The networking subsystem is unavailable
10051	swErrorNetworkUnreachable	The specified network is unreachable
10052	swErrorNetworkReset	Network dropped connection on reset
10053	swErrorConnectionAborted	Connection was aborted due to timeout or other failure
10054	swErrorConnectionReset	Connection was reset by remote network
10055	swErrorOutOfBuffers	No buffer space is available
10056	swErrorAlreadyConnected	Connection already established with remote host
10057	swErrorNotConnected	No connection established with remote host
10058	swErrorConnectionShutdown	Unable to send or receive data after connection shutdown
10060	swErrorOperationTimeout	The specified operation has timed out
10061	swErrorConnectionRefused	The connection has been refused by the remote host
10064	swErrorHostUnavailable	The specified host is unavailable
10065	swErrorHostUnreachable	The specified host is unreachable
10067	swErrorTooManyProcesses	Too many processes are using the networking subsystem
10091	swErrorNetworkNotReady	Network subsystem is not ready for communication
10092	swErrorInvalidVersion	This version of the operating system is not supported
10093	swErrorNetworkNotInitialized	The networking subsystem has not been initialized
10101	swErrorRemoteShutdown	The remote host has initiated a graceful shutdown sequence
11001	swErrorInvalidHostName	The specified hostname is invalid or could not be resolved
11002	swErrorHostNameNotFound	The specified hostname could not be found
11003	swErrorHostNameRefused	Unable to resolve hostname, request refused
11004	swErrorHostNameNotResolved	Unable to resolve hostname, no address for specified host
12001	swErrorInvalidLicense	The license for this product is invalid
12002	swErrorProductNotLicensed	This product is not licensed to perform this operation
12003	swErrorNotImplemented	This function has not been implemented on this platform
12004	swErrorUnknownLocalHost	Unable to determine local host name
12005	swErrorInvalidHostAddress	Invalid host address specified
12006	swErrorInvalidServicePort	Invalid service port number specified

12007	swErrorInvalidServiceName	Invalid or unknown service name specified
12008	swErrorInvalidEventId	Invalid event identifier specified
12009	swErrorOperationNotBlocking	No blocking operation in progress on this socket
12101	swErrorSecurityNotInitialized	Unable to initialize security interface for this process
12102	swErrorSecurityContext	Unable to establish security context for this session
12103	swErrorSecurityCredentials	Unable to open client certificate store or establish client credentials
12104	swErrorSecurityCertificate	Unable to validate the certificate chain for this session
12105	swErrorSecurityDecryption	Unable to decrypt data stream
12106	swErrorSecurityEncryption	Unable to encrypt data stream
12201	swErrorOperationNotSupported	The specified operation is not supported
12330	swErrorFeatureNotSupported	The specified feature is not supported
12337	swErrorMaximumConnections	The maximum number of client connections exceeded
12338	swErrorThreadCreationFailed	Unable to create a new thread for the current process
12339	swErrorInvalidThreadHandle	The specified thread handle is no longer valid
12340	swErrorThreadTerminated	The specified thread has been terminated
12341	swErrorThreadDeadlock	The operation would result in the current thread becoming deadlocked
12342	swErrorInvalidClientMoniker	The specified moniker is not associated with any client session
12343	swErrorClientMonikerExists	The specified moniker has been assigned to another client session
12344	swErrorServerInactive	The specified server is not listening for client connections
12345	swErrorServerSuspended	The specified server is suspended and not accepting client connections

LlmClient ActiveX Control

The **LlmClient** ActiveX control provides a simple, high-level interface for integrating large language model (LLM) capabilities into Windows applications. The control is designed for developers using COM-compatible development tools such as Visual Basic 6.0, VBA, Delphi, PowerBuilder, and scripting environments that support ActiveX automation.

The control enables developers to quickly add AI-powered functionality to existing applications without needing to directly work with REST APIs, JSON payloads, HTTP requests, or provider-specific implementation details. Using familiar COM properties, methods, and events, applications can send prompts, receive responses, manage conversation history, and interact with modern AI services using a traditional Windows programming model.

Control Information

File Name	CSLLMX12.OCX
Version	12.0.3024.1286
ProgID	SocketTools.LlmClient.12
ClassID	79FA9AF1-C367-4F24-9E8A-1886AC2581E1
Threading Model	Apartment
Help File	CST12CTL.CHM
Dependencies	None

Overview

The **LlmClient** ActiveX control is built around a session-based architecture that manages all aspects of interacting with a language model, including connection settings, provider configuration, conversation history, and model selection. It automatically maintains conversational state between requests, making it easier to create interactive applications without manually tracking prior prompts or responses. By providing a consistent interface across multiple AI providers and models, it allows applications to switch between services with minimal code changes. Developers can enumerate providers and models, query supported capabilities, configure default behavior, and adjust settings such as token limits, reasoning levels, and generation parameters at runtime.

A primary goal of the control is to simplify the integration of AI features into both modern and legacy Windows applications. Developers can work with large language models using familiar COM automation techniques while the control internally handles low-level details such as HTTPS connections, request formatting, JSON serialization, authentication, and response parsing. This allows applications to communicate with AI services using a familiar programming model that is consistent with traditional ActiveX and COM development.

The control can be added to a form at design time or created dynamically at runtime using standard

COM automation techniques. This makes it suitable for desktop applications, scripting environments, Microsoft Office automation, and other solutions that rely on COM-compatible components.

The control also includes comprehensive support for managing conversation history and session state. Applications can enumerate previous messages and responses, search message history, import or export conversation data, and automatically limit retained context to help manage token usage and provider limitations.

In addition to messaging functionality, the control includes utility features for estimating and tracking token usage, validating prompts and model names, managing cached provider information, and logging diagnostic information for debugging purposes. These capabilities help developers better understand how their applications interact with AI services and assist in identifying configuration or performance issues.

The **LlmClient** control makes it practical to add AI-powered features such as chat assistants, automated responses, content generation, text analysis, and workflow automation to existing Windows applications while preserving compatibility with your current development tools.

Requirements

The SocketTools ActiveX Edition components are self-registering controls that are compatible with any programming language that supports the Component Object Model (COM) and the ActiveX control specification. If you are using Visual Basic 6.0, Service Pack 6 (SP6) is required. We recommend installing all available updates for your development tools. Although the Visual Basic 6.0 runtime is supported on Windows 11, the IDE itself is no longer officially supported by Microsoft. Legacy IDEs and compilers may also require elevated (administrator) privileges to run properly.

The ActiveX controls are supported on Windows 7, Windows Server 2008 R2, and later versions of both desktop and server editions of Windows. For Windows 7, Service Pack 1 (SP1) is the minimum requirement. For Windows 8 systems, the 8.1 update must be installed. On ARM-based platforms, the minimum supported version is Windows 10 build 1709.

SocketTools includes components for both 32-bit (x86) and 64-bit (x64) Windows platforms. All modern versions of Windows are 64-bit, but we continue to include 32-bit components for compatibility with legacy development tools such as Visual Basic 6.0. We also provide native ARM64 ActiveX controls for systems running Windows on ARM. Note that 32-bit applications on ARM run using x86 emulation, and Microsoft no longer supports native ARM32 applications.

If you are using VBScript, Visual Basic for Applications (VBA), or another scripting environment on an ARM-based system, be aware that 64-bit hosts will require ARM64 components, while 32-bit hosts will use x86 components under emulation. This includes applications created with Visual Basic 6.0. To reduce deployment complexity and avoid confusion, SocketTools does not include ARM32 ActiveX controls in its standard redistribution packages but they are available on request for legacy or specialized scenarios.

Distribution

When you distribute an application that uses this control, you can either install the file in the same folder as your application executable or as a shared component in the appropriate system folder. If you install the control in the system folder, it is important that you distribute the correct version for the target platform and it must be registered. If you install the control in the same folder as your executable, it is recommended that you use registration-free activation or COM redirection to ensure that the correct version of the control is loaded by the application.

LlmClient Control Properties

Property	Description
ApiKey	The API key used to authenticate requests with the selected provider.
ApiVersion	The API version used when a provider requires an explicit version string.
ApplicationName	The application name used to identify the client.
BaseUrl	The base URL for the provider endpoint. Set this for local servers or custom provider endpoints.
CacheTime	The number of seconds provider and model information should remain cached.
ContextSize	The maximum context window size, in tokens, reported for the current model.
ContextUsed	The estimated number of context tokens currently used by the session history.
DefaultModel	The default model name for the current provider.
ElapsedTime	The elapsed time, in milliseconds, for the most recent request.
HistorySize	The maximum number of message exchanges retained in the client history.
HttpStatus	The HTTP status code returned by the server for the most recent request.
IdleTime	The number of seconds an idle connection can remain open before it is reconnected.
InputTokens	The number of input tokens used by the most recent prompt.
IsBlocked	Indicates whether the control is waiting for an operation to complete.
IsConnected	Indicates whether the control is currently connected to a provider.
IsInitialized	Indicates whether the control has been initialized.
IsLocal	Indicates whether the selected provider is a locally hosted service.
KeepAlive	Indicates whether persistent HTTP connections should be used when possible.
LastError	The most recent error code set by the control.
LastErrorString	A description of the most recent error code set by the control.
MaxTokens	The maximum number of tokens that may be generated for a response.
MessageCount	The number of messages currently stored in the conversation history.
MessageId	The unique message ID assigned to the most recent prompt and response.
ModelFlags	The capability flags associated with the current model.
ModelName	The name of the current model used for requests.
Options	The connection and session options used by the control.
OrganizationId	An organization or tenant identifier that may be used by the selected provider.
OutputTokens	The number of output tokens generated by the most recent response.
ProjectId	A project identifier that may be used by the selected provider.
Prompt	The most recent prompt sent to the current model.
Provider	The identifier for the current provider used to establish a connection.
ProviderFlags	The capability and requirement flags associated with the selected provider.
ProviderName	The name of the current provider used to establish a connection.

ReasoningLevel	The preferred reasoning effort level used for models that support reasoning.
Response	The response to the most recent message prompt sent to the model.
ResponseId	The provider-assigned identifier for the most recent response.
ResponseModel	The model name reported by the provider for the most recent response.
ResponseStatus	The completion status for the most recent response.
Secure	Indicates whether secure HTTPS connections are required.
SystemPrompt	The system prompt used to provide instructions for the model.
Temperature	The sampling temperature used to control response variability.
ThrowError	Indicates whether the control should raise an error event or exception when an operation fails.
Timeout	The maximum number of seconds to wait for a request to complete.
Timestamp	The date and time the last response was received.
TotalTokens	The total number of tokens used by the most recent request and response.
TopK	The top-k sampling value used by providers and models that support it.
TopP	The nucleus sampling value used to control token selection.
Trace	Indicates whether diagnostic logging is enabled.
TraceFile	The file name used to store diagnostic trace output.
TraceFlags	The options that control the type of diagnostic information written.
UserAgent	The user agent string sent with provider requests.
UserId	The provider-specific user identifier associated with requests.
Version	The current version of the control.

ApiKey Property

Sets or returns the API key used for the current session.

Syntax

object.ApiKey [= *value*]

Remarks

The **ApiKey** property is a String value that specifies the API key used to authenticate with the provider. The API key may be provided using a literal string, an environment variable, or a value stored in the Windows Credential Manager. Using an environment variable or secure credential storage is recommended for production applications to avoid exposing sensitive information in source code or application binaries.

If the selected provider requires authentication, the API key can be provided in several formats, allowing applications to provide credentials in a way that balances convenience and security:

- **Literal string**

The API key is provided directly as a string. This is the simplest approach and is convenient for testing or small internal tools, but it is not recommended for production applications. The string may be exposed in source code, configuration files, diagnostic logs or the compiled application binary.

- **Environment variable**

The name of an environment variable enclosed in percent symbols, for example **"%OPENAI_API_KEY%"**. The value of the environment variable is used as the API key. This avoids embedding the key directly in the application and is useful for development, scripts and deployment environments. However, environment variables may still be visible to the current user, inherited by child processes or exposed through system configuration, so they should still be protected appropriately.

- **Windows credential**

A credential name enclosed in braces, for example **"{MyAppName/OpenAI}"**. The API key is retrieved from the Windows Credential Manager using the specified name. This is the recommended approach for most Windows applications because the secret is stored outside the application and managed by the operating system. The credential can be created manually using Credential Manager, or programmatically by the application using the Windows Credential Management API. Applications should choose a unique credential name and document it clearly if users or administrators are expected to configure the value themselves.

For production applications, it is recommended that you avoid using literal API key strings and instead use an environment variable or a value stored in the Windows Credential Manager. If you must provide the API key as a literal string, you should take additional steps to protect it, such as storing the key in an encrypted form and limiting access to authorized users or processes. Avoid embedding API keys directly in application source code, configuration files, installers or other content that could be exposed through version control systems, logs or public repositories.

Data Type

String

See Also

ApiVersion Property

Sets or returns the API version used when a provider requires an explicit version string.

Syntax

object.**ApiVersion** [= *value*]

Remarks

The **ApiVersion** property is a String value that specifies the API version used when communicating with providers that require an explicit version identifier as part of the request. Applications should only set this property if the provider documentation specifically requires an API version. Preview or experimental API versions may introduce compatibility changes and should be used with caution in production applications.

Some providers, particularly Microsoft Foundry and Azure OpenAI deployments, require applications to specify an API version string with each request. The version identifies the format and capabilities of the service endpoint being used. The version string is typically assigned by the provider and may correspond to a specific release date or preview version. For example, a Foundry deployment may require an API version such as **"2024-05-01-preview"** or **"2024-10-21"**. If an incorrect or unsupported version is specified, the provider may reject the request or return an error indicating that the requested API version is invalid.

Providers may also use API versions internally through request headers rather than query parameters. For example, Anthropic requests include a version header that identifies the expected API behavior. In most cases, the control will automatically provide the appropriate default value and the application does not need to explicitly set this property.

Data Type

String

See Also

[BaseUrl Property](#), [Provider Property](#), [ProviderName Property](#), [Connect Method](#)

ApplicationName Property

Sets or returns the application name used to identify the client.

Syntax

object.ApplicationName [= *value*]

Remarks

The **ApplicationName** property is a String value that specifies the application name associated with requests sent by the control. This value is included as part of the default user-agent string and may be used for diagnostic and identification purposes by the provider. Setting this property allows applications to provide a more meaningful name that can help identify requests in provider dashboards, logs or diagnostic output.

A recommended format is to specify both the application name and version number using a convention similar to standard user-agent strings, for example:

"MyApplication/1.0"

The control may normalize the application name by removing unsupported characters or replacing whitespace characters to ensure the value is suitable for use in HTTP headers and diagnostic output. If the property is set to an empty string, no custom application name will be included in the default user-agent string.

Data Type

String

See Also

[UserAgent Property](#), [Connect Method](#)

BaseUrl Property

Sets or returns the base URL endpoint for the current provider.

Syntax

object.BaseUrl [= *value*]

Remarks

The **BaseUrl** property is a String value that specifies the base URL endpoint used when communicating with the selected provider. The base URL identifies the server and API endpoint that will receive requests generated by the control. If you do not change this property, it will return the default endpoint used for the service provider specified by the **Provider** property.

For most cloud providers, the control automatically uses an appropriate default endpoint and this property does not need to be explicitly set. However, applications may need to set this property when using a locally hosted model, a self-hosted service, or a custom provider deployment.

For example, locally hosted model servers such as LM Studio or Ollama commonly expose an OpenAI-compatible endpoint using a URL similar to:

```
"http://127.0.0.1:1234/v1/"
```

Applications using Microsoft Foundry or Azure OpenAI deployments must specify the endpoint URL assigned to the deployment because those services do not use a single shared public endpoint.

To determine the endpoint URL for a Microsoft Foundry or Azure OpenAI deployment, refer to the Azure portal for the resource or deployment. The portal will provide the endpoint URL and API key values associated with the deployment. In managed enterprise environments, these values may be provided by the administrator responsible for the Azure or Foundry resources.

In most cases, applications should use the default endpoint associated with the selected provider. Providing an incorrect endpoint URL may prevent the control from connecting to the service provider. If this property is set to an empty string, the control will revert to using the default endpoint associated with the selected provider.

Data Type

String

Example

```
LlmClient1.ProviderName = "Local"
LlmClient1.BaseUrl = "http://127.0.0.1:1234/v1/"
LlmClient1.ModelName = "mistralai/mistral-7b-instruct-v0.3"

' Connect to a locally hosted model using LM Studio
If LlmClient1.Connect() Then
    LlmClient1.Prompt = "How do you calculate the volume of a sphere?"

    ' Send the prompt to the model and display the response
    If LlmClient1.SendMessage() Then
        MsgBox LlmClient1.Response, vbInformation, "Message " &
LlmClient1.MessageId
    Else
        MsgBox LlmClient1.LastErrorString, vbExclamation, "Error"
    End If
```

```
LlmClient1.Disconnect
Else
    ' Unable to connect to the local server
    MsgBox LlmClient1.LastErrorString, vbExclamation, "Error"
End If
```

See Also

[ApiVersion Property](#), [ModelName Property](#), [ProviderName Property](#), [Connect Method](#), [SendMessage Method](#)

Blocking Property

Gets and sets the blocking state of the control.

Syntax

object.**Blocking** [= { True | False }]

Remarks

Setting the **Blocking** property determines if control actions complete synchronously or asynchronously. If set to True, then each control action, such as sending or receiving data, will return when the operation has completed or timed-out. If set to False, control actions will return immediately. If the operation would result in the control blocking, such as attempting to read data when none has been written, an error is generated.

Data Type

Boolean

See Also

[IsBlocked Property](#)

CacheTime Property

Sets or returns the number of seconds provider and model information should remain cached.

Syntax

object.CacheTime [= *value*]

Remarks

The **CacheTime** property is an Integer value that specifies the number of seconds provider information and model information should remain cached by the control.

The control may cache information such as provider capabilities, available models and model metadata to reduce unnecessary network requests and improve performance. Cached information may be reused until the cache interval expires.

In most cases, the default cache interval is appropriate and this property does not need to be changed. Reducing the cache time may increase network activity and provider requests, while increasing the cache time may delay visibility of changes such as newly available models or updated provider capabilities.

Setting this property to zero disables caching and forces the control to request updated provider and model information whenever needed.

Data Type

Integer (Int32)

See Also

[ModelFlags Property](#), [ModelName Property](#), [GetFirstModel Method](#), [GetNextModel Method](#)

ContextSize Property

Returns the maximum context window size, in tokens, reported for the current model.

Syntax

object.ContextSize

Remarks

The **ContextSize** property is an Integer value that specifies the maximum context window size, in tokens, reported for the current model. The context window represents the total amount of text the model can process in a single request, including prompts, responses, system instructions and retained conversation history. Models with larger context windows can generally process longer conversations, larger documents and more extensive prompts before older content must be discarded or truncated.

Most cloud-based service providers offer models which support very large context windows while limiting the maximum number of tokens that can be generated in a single response. For example, a model may support a context window of 1,000,000 tokens, allowing it to process very large conversations or documents, while limiting individual responses to 128,000 output tokens.

The context window size returned by this property is advisory. The value should be treated as general guidance and is not enforced by the control. The actual limits on the context size may vary depending on the provider, model version, deployment, enabled features and user account. A value of zero means the context size cannot be determined for the current model. For locally hosted models or cloud-based aggregators, these limits may also be configurable for a specific model.

Data Type

Integer (Int32)

See Also

[ContextUsed Property](#), [InputTokens Property](#), [MaxTokens Property](#), [ModelName Property](#), [OutputTokens Property](#), [TotalTokens Property](#)

ContextUsed Property

Returns the estimated number of context tokens currently used by the session history.

Syntax

object.ContextUsed

Remarks

The **ContextUsed** property is an Integer value that returns the estimated number of context tokens currently used by the active session history. This includes tokens associated with prompts, responses, system instructions and other retained conversation content managed by the control.

As additional messages are exchanged with the model, the amount of context used by the session will generally increase. When the accumulated context approaches the maximum context window supported by the model, older messages may need to be removed or truncated to remain within the model limits.

The value returned by this property is an estimate calculated by the control and may differ from the exact token usage reported by the service provider. Token usage can vary depending on the provider, model, tokenizer implementation and internal formatting used when constructing requests.

This property is primarily intended for informational or diagnostic purposes and should not be interpreted as an exact measurement of the provider's internal token usage.

Data Type

Integer (Int32)

See Also

[ContextSize Property](#), [HistorySize Property](#), [InputTokens Property](#), [MessageCount Property](#), [OutputTokens Property](#), [TotalTokens Property](#)

DefaultModel Property

Returns the default model name for the current provider.

Syntax

object.DefaultModel

Remarks

The **DefaultModel** property returns the default model name associated with the current provider. This is the model that will be used if a session is created or connected without explicitly specifying a model name. In most cases, the default model is selected to provide a balance of performance and cost, typically favoring smaller, faster models that are suitable for general use. For more information about providers and their default models, refer to the [Large Language Model Providers](#) section.

Applications can use this property to determine a suitable default model for a provider, or to present a default selection to the user. The default model may change over time as providers update, replace or retire existing models. Applications that require consistent behavior should explicitly specify a model name instead of relying on the provider default.

Data Type

String

See Also

[ModelName Property](#), [Provider Property](#), [ProviderName Property](#), [GetProvider Method](#)

ElapsedTime Property

Returns the elapsed time, in milliseconds, for the most recent request.

Syntax

object.ElapsedTime

Remarks

The **ElapsedTime** property is an Integer value that returns the elapsed time, in milliseconds, for the most recent request processed by the control.

The elapsed time includes the total amount of time required to send the request to the provider, wait for the response and process the returned data. The reported value may be affected by network latency, provider response time, model complexity and the size of the request or response.

This property is primarily intended for informational or diagnostic purposes and should not be interpreted as a precise performance benchmark.

Data Type

Integer (Int32)

See Also

[LastError Property](#), [HttpStatus Property](#), [ResponseStatus Property](#), [Timeout Property](#), [SendMessage Method](#)

HistorySize Property

Sets or returns the maximum number of message exchanges retained in the client history.

Syntax

`object.HistorySize [= value ]`

Remarks

The **HistorySize** property is an Integer value that specifies the maximum number of message exchanges retained in the client session history. Each message represents a single request submitted to the model and its associated response. Changing the value of this property will change how many messages the client will retain in memory. It is possible to disable the conversation history by setting the value to zero.

The conversation history is maintained on a per-session basis and reflects the sequence of interactions with the model. Messages are stored in chronological order, with new messages appended to the end of the history. When the number of messages exceeds the value of this property, the oldest messages are removed automatically. This ensures that the total number of stored messages does not exceed the configured maximum.

Reducing the history size can help limit memory usage and reduce the amount of context sent with each request, which may improve performance and reduce token usage. However, limiting the history size may also reduce the model's ability to maintain context across multiple interactions.

Disabling the conversation history does not provide additional security or privacy. It only affects whether previous messages are retained and automatically included in subsequent requests. The content of each request is still transmitted to the service provider and may be processed or stored in accordance with that provider's policies. Applications that require secure handling of sensitive information should avoid including confidential data in requests and review the data handling practices of the selected service provider.

Even when message history is disabled, the model may still produce responses that appear contextually relevant within a single interaction. This is because the current request itself may contain enough information for the model to generate an appropriate response. However, without retaining previous messages, the model does not have access to prior exchanges in the conversation and continuity across multiple requests may be limited. In most cases, retaining a moderate history size provides better results for conversational applications.

The default history size is 100 message exchanges.

Data Type

Integer (Int32)

See Also

[ContextUsed Property](#), [MessageCount Property](#), [Prompt Property](#), [Response Property](#), [ClearHistory Method](#), [SendMessage Method](#)

HttpStatus Property

Returns the HTTP status code returned by the server for the most recent request.

Syntax

`object.HttpStatus`

Remarks

The **HttpStatus** property returns the HTTP status code returned by the provider for the most recent request made by the control. This value reflects the result of the underlying HTTP operation used to communicate with the service provider.

HTTP status codes are three-digit numeric values which indicate whether a request was successful or if an error occurred. They may be interpreted using the following general ranges:

Value	Description
100-199	Informational responses. These are rarely used in practice and indicate that the request has been received and processing is continuing.
200-299	Successful responses. The request was successfully processed by the provider. A value of 200 (OK) is typically returned for successful API requests.
300-399	Redirection responses. These indicate that additional action may be required to complete the request. These responses are uncommon for API endpoints.
400-499	Client errors. The request was invalid or could not be processed by the provider. This may indicate issues such as invalid parameters, missing authentication credentials, or rate limiting.
500-599	Server errors. The provider encountered an error while processing the request. These errors are often transient and the request may succeed if the request is retried.

This property can be used with the return value of methods such as **Connect** or **SendMessage** to help determine the cause of a failure. The status code may provide additional information about why a request was rejected or processed with an error condition by the provider. For example, if a request fails and the status code is 503, this indicates the service is temporarily unavailable.

HTTP status codes are returned by the provider service and their exact meaning may vary slightly between providers. Some providers may also return additional diagnostic information in the response body which can help identify the specific cause of the error. Here are some common error status codes and what they could mean in the context of the client session:

- **400 Bad Request** - The request was malformed or contained invalid parameters. This usually indicates an internal error in the library where a request was not composed correctly. This could occur if the service provider does not support certain functionality, an invalid option was used, or an incorrect endpoint was specified.
- **401 Unauthorized** - The API key is missing, invalid, or expired. If you are using an environment variable or Windows credential, check to make sure it is defined and contains the correct value. If you continue to experience this error, check the provider account to ensure the key has not been revoked or replaced.
- **403 Forbidden** - The request was understood, but the provider refused to process it. This can

occur if the account does not have permission to use the selected model, endpoint, organization, or project. Verify that the API key has access to the requested resource and that billing or account restrictions are not preventing the request.

- **404 Not Found** - The requested resource could not be found. This commonly indicates an incorrect endpoint URL, deployment name, model name, or provider-specific path. Verify that the provider, base URL, and model name are correct for the account being used.
- **408 Request Timeout** - The provider did not complete the request before the timeout expired. This can occur because of network latency, a temporary service issue, a large prompt, or a model that requires more time to generate a response. Consider increasing the timeout value, reducing the prompt or history size, or retrying the request later.
- **409 Conflict** - The request conflicts with the current state of the service or resource. This is uncommon for simple message requests, but may occur with provider-specific operations, duplicate requests, or incompatible settings. Review the request options and retry the operation after any pending provider-side operation has completed.
- **413 Payload Too Large** - The request body is larger than the provider allows. This usually means the prompt, conversation history, attached content, or generated request JSON exceeds the model or endpoint limit. Reduce the prompt size, clear or shorten the conversation history, or select a model with a larger context size. The **TrimHistory** method can be used to reduce the amount of conversation history included with a prompt.
- **415 Unsupported Media Type** - The provider does not support the request content type or encoding. This can indicate that the request was not submitted as JSON, that the wrong endpoint was used, or that the provider does not support the submitted content format. Verify the endpoint and make sure the request format matches the provider requirements.
- **422 Unprocessable Entity** - The provider accepted the request format, but could not process the request contents. This can occur if a model option, reasoning level, response format, tool definition, or other provider-specific setting is not valid for the selected model. Review the selected model and options, and disable unsupported features.
- **429 Too Many Requests** - The provider rejected the request because a rate limit, usage limit, or account quota was exceeded. Applications should wait before retrying the request, reduce the request rate, and avoid retrying immediately in a tight loop. If the error persists, review the provider account limits, billing status, and usage quotas.
- **500 Internal Server Error** - The provider encountered an unexpected server-side error while processing the request. This usually indicates a temporary problem with the provider rather than the application. Retry the request later, and check the provider status page if the problem continues.
- **502 Bad Gateway** - A gateway or proxy received an invalid response from an upstream service. This is typically a temporary provider-side or network condition. Retry the request after a short delay, and check whether the provider is experiencing a service disruption.
- **503 Service Unavailable** - The service is temporarily unavailable because of maintenance, overload, or resource limits. Retry the request after a delay. If the provider returns a retry interval, the application should wait at least that long before trying again.
- **504 Gateway Timeout** - A gateway or proxy timed out waiting for an upstream service to complete the request. This can occur when the provider is under heavy load or when a

response takes too long to generate. Retry the request later, reduce the prompt size, or request a shorter response.

If no request has been made, or if the client has not yet received a response from the provider, the return value will be zero. The value of this property is reset with each request made to the provider and is updated when the server responds to the request, either with a successful completion status or an error condition.

Data Type

Integer (Int32)

See Also

[LastError Property](#), [LastErrorString Property](#), [ResponseStatus Property](#), [Connect Method](#), [SendMessage Method](#)

IdleTime Property

Sets or returns the number of seconds an idle connection can remain open before it is reconnected.

Syntax

`object.IdleTime [= value ]`

Remarks

The **IdleTime** property returns the current idle timeout period, in seconds, for the client session. Setting this property changes the current idle timeout for the client session. This value determines how long a connection can remain idle between requests before the control automatically closes and re-establishes the underlying HTTP connection.

Idle time is used to balance performance and reliability. Reusing an existing connection can reduce overhead and improve performance, particularly when multiple requests are made in quick succession. However, connections that remain idle for extended periods may be closed by the server or by intermediate network infrastructure. When the idle time is exceeded, the control will proactively establish a new connection before sending the next request.

This property is distinct from the **Timeout** and **CacheTime** properties. The **Timeout** property specifies how long the client will wait for a response to a request before failing, while the **CacheTime** property controls how long certain responses or metadata may be reused without making a new request. The idle time only affects how long an existing connection is retained between requests.

If this property is set to zero, a new connection is established for each request. In most cases, the default idle time provides a good balance between performance and compatibility.

It is important to note that this setting only affects client-side behavior. Increasing the idle time does not guarantee a server will keep the connection open for that duration. Many servers will close idle connections after a shorter period of time, in which case the control will automatically reconnect as needed.

Data Type

Integer (Int32)

See Also

[CacheTime Property](#), [KeepAlive Property](#), [Timeout Property](#), [Connect Method](#), [SendMessage Method](#)

InputTokens Property

Returns the number of tokens used by the most recent prompt.

Syntax

object.InputTokens

Remarks

The **InputTokens** property returns the number of input tokens used by the most recent prompt sent to the model. This value reflects the number of tokens consumed by the prompt and any associated context included with the request.

Token counts are determined by the model provider and may vary depending on the content of the prompt, the model being used and how the provider processes the request. Token counts do not directly correspond to characters or words, and the same text may produce different token counts when used with different models.

If no prompt has been sent, or if the request failed before the provider returned token usage information, this property will return zero.

Data Type

Integer (Int32)

See Also

[OutputTokens Property](#), [TotalTokens Property](#), [EstimateTokens Method](#), [SendMessage Method](#)

IsBlocked Property

Indicates whether the control is waiting for an operation to complete.

Syntax

object.IsBlocked

Remarks

The **IsBlocked** property can be used to determine whether the control is currently waiting for an operation to complete, such as establishing a connection, retrieving provider or model information, or sending a prompt to a model.

When a request is sent using the **SendMessage** method, the control will wait until the request has completed, the server has responded, or a timeout has occurred. If a request is performed in the main UI thread of the application, it is recommended that the application display some visual indication that the operation is in progress.

This property is primarily intended for applications that need to monitor the state of the control while processing other events or performing operations that may take a noticeable amount of time to complete.

Data Type

Boolean

See Also

[IsConnected Property](#), [LastError Property](#), [Timeout Property](#), [Connect Method](#), [SendMessage Method](#)

IsConnected Property

Indicates whether the control is connected to a server.

Syntax

object.IsConnected

Remarks

The **IsConnected** property indicates whether there is an active session and the client has successfully authenticated with the API server. Checking the value of this property is not simply a passive status check. The network connection to the provider may be transient and can be automatically re-established if the client session has been idle. The **IsConnected** property may cause the control to reconnect and re-authenticate with the server if necessary.

If the control must re-authenticate, it will attempt to reconnect to the server and validate the selected model for the session. If the server reports an error condition, such as an invalid API key, the connection will not be re-established and the property will return **False**.

Data Type

Boolean

See Also

[IsBlocked Property](#), [IsInitialized Property](#), [Timeout Property](#), [Connect Method](#)

IsInitialized Property

Indicates whether the control has been initialized.

Syntax

object.IsInitialized

Remarks

The **IsInitialized** property is used to determine if the current instance of the control has been initialized properly. Normally this is done automatically when the control is loaded; however, there are circumstances where the control may not be able to initialize itself. If this property returns **False**, the application must call the **Initialize** method before performing any other operation.

The most common reason that the control may not initialize correctly is that no valid license key can be found or the license key that was provided is invalid. It may also indicate a problem with the system configuration or user access rights, such as not being able to load the required networking libraries or not being able to access the system registry.

Data Type

Boolean

See Also

[Connect Method](#), [Initialize Method](#)

IsLocal Property

Indicates whether the selected provider is a locally hosted service.

Syntax

object.IsLocal

Remarks

The **IsLocal** property indicates whether the currently selected provider is a locally hosted service. This property returns **True** for providers which communicate with a service running on the local system or a private network, rather than a public cloud service.

Applications can use this property to adjust their behavior or user interface based on whether requests are processed locally or by a remote provider. For example, an application may choose to display different configuration options for local providers, allow non-secure HTTP connections for local testing, or provide different guidance regarding model availability and performance.

If no provider has been selected, this property will return **False**.

Data Type

Boolean

See Also

[BaseUrl Property](#), [Provider Property](#), [ProviderFlags Property](#), [ProviderName Property](#), [Secure Property](#), [Connect Method](#)

KeepAlive Property

Indicates whether persistent HTTP connections should be used when possible.

Syntax

object.KeepAlive [= *value*]

Remarks

The **KeepAlive** property determines whether the control will attempt to reuse existing HTTP connections when communicating with the provider. When this property is set to **True**, the control may retain an active connection between requests to reduce connection overhead and improve performance.

Persistent connections are most beneficial when multiple requests are sent within a relatively short period of time. Reusing an existing connection can reduce network latency and avoid the overhead of establishing a new connection for each request.

This property works in conjunction with the **IdleTime** property, which specifies how long an idle connection may remain open before it is closed and re-established. If **KeepAlive** is set to **False**, the idle timeout value is ignored and a new connection will be established for each request.

Idle connections are typically closed automatically by the provider or intermediate network infrastructure after a period of inactivity. If a persistent connection is no longer valid, the control will automatically reconnect as needed. Checking the **IsConnected** property may cause the control to re-establish a connection.

Data Type

Boolean

See Also

[IdleTime Property](#), [IsConnected Property](#), [Timeout Property](#), [Connect Method](#), [Disconnect Method](#), [SendMessage Method](#)

LastError Property

Returns the last error that occurred for the control.

Syntax

object.LastError [= *value*]

Remarks

The **LastError** property can be used to determine the last error that occurred for the control. If a value is assigned to this property, it should either be zero to clear the current error or a valid error code for the control. Refer to the list of [error codes](#) for information about specific errors.

Data Type

Integer (Int32)

See Also

[LastErrorString Property](#), [OnError Event](#)

LastErrorString Property

Return a description of the last error that occurred.

Syntax

object.LastErrorString

Remarks

The **LastErrorString** property returns a description of the last error that occurred. This property can be used to display a meaningful error message to the user rather than only the numeric value returned by the **LastError** property. The error descriptions returned by this property are currently provided in English and are not localized based on the system locale or user language settings.

Data Type

String

See Also

[LastError Property](#), [OnError Event](#)

MaxTokens Property

Sets or returns the maximum number of tokens that may be generated for a response.

Syntax

object.MaxTokens [= *value*]

Remarks

The **MaxTokens** property specifies the maximum number of tokens the model may generate in response to a request. This value can be used to limit the length of responses returned by the model.

This property only affects generated output tokens and does not increase the total context window supported by the selected model. Increasing the value of this property cannot force a provider or model to accept larger prompts or additional conversation history beyond the model's supported limits.

Smaller values can reduce response length, improve response times and lower token usage costs. However, values that are too small may cause responses to be truncated or incomplete. If this property is set to zero, the provider or model default will be used. Some providers may also impose their own limits on the maximum number of output tokens that can be generated for a single request.

Data Type

Integer (Int32)

See Also

[ContextSize Property](#), [ContextUsed Property](#), [InputTokens Property](#), [OutputTokens Property](#), [TotalTokens Property](#), [EstimateTokens Method](#), [SendMessage Method](#)

MessageCount Property

Returns the number of messages currently stored in the conversation history.

Syntax

object.MessageCount

Remarks

The **MessageCount** property returns the number of messages currently stored in the client conversation history. Each message represents a single prompt submitted to the model and its associated response.

The conversation history is maintained on a per-session basis and reflects the sequence of interactions performed using the control. Messages are stored in chronological order, with new messages appended to the end of the history. To retrieve the contents of a specific message and response from the history, use the **GetMessage** method.

It is possible to disable the conversation history by setting the **HistorySize** property to zero. In this case, this property will always return zero.

Data Type

Integer (Int32)

See Also

[HistorySize Property](#), [ClearHistory Method](#), [GetMessage Method](#), [TrimHistory Method](#)

MessageId Property

Returns the unique message ID assigned to the most recent prompt and response.

Syntax

object.**MessageId**

Remarks

The **MessageId** property returns a numeric identifier for the most recent prompt and response. If the control is not connected to a provider, or a prompt has not been sent, this property will return zero.

Message identifiers are session-specific and are guaranteed to be unique only within the client session in which they were created. Applications must not rely on the internal assignment strategy used to generate these identifiers. The only guaranteed behavior is that newer messages will always receive larger identifier values than older messages.

The **GetMessage** method can be used to retrieve the prompt and response for a specific message.

Data Type

Integer (Int32)

See Also

[MessageCount Property](#), [Prompt Property](#), [Response Property](#), [Timestamp Property](#), [FindMessage Method](#), [GetMessage Method](#), [SendMessage Method](#)

ModelFlags Property

Returns or changes the capability flags associated with the current model.

Syntax

`object.ModelFlags [= value ]`

Remarks

The **ModelFlags** property returns a set of bit flags that describe the capabilities supported by the current model associated with the client session. These flags can be used by applications to determine which features are available and adjust behavior accordingly. The value may be one or more of the following flags:

Constant	Value	Description
IlmModelFlagNone	&H0000	No model capabilities defined.
IlmModelFlagChat	&H0001	Supports conversational text generation.
IlmModelFlagSystemRole	&H0002	Accepts a system role message in the input.
IlmModelFlagStreaming	&H0004	Supports streaming responses.
IlmModelFlagStructured	&H0008	Supports structured output (e.g., JSON or schema).
IlmModelFlagVision	&H0010	Supports image inputs (multimodal).
IlmModelFlagTools	&H0020	Supports tool or function calling.
IlmModelFlagReasoning	&H0040	Supports reasoning-oriented generation.
IlmModelFlagResponses	&H0080	Supports the Responses API (unified endpoint).
IlmModelFlagFunctions	&H0100	Supports OpenAI-style function calling with schemas.
IlmModelFlagAudio	&H0200	Supports audio output (text-to-speech).
IlmModelFlagImage	&H0400	Supports image generation.
IlmModelFlagVideo	&H0800	Supports video generation.
IlmModelFlagTranscription	&H1000	Supports speech-to-text transcription.
IlmModelFlagInstructions	&H2000	Supports a dedicated instruction field outside message lists.
IlmModelFlagMaxCompletionTokens	&H4000	Uses max_completion_tokens instead of max_tokens in requests.
IlmModelFlagInferred	&H80000	Capabilities are inferred rather than explicitly defined.

Model capabilities may vary between providers and even between models offered by the same provider. Not all providers return complete capability information when enumerating models. In these cases, some flags may be inferred by the control based on the model name and known characteristics

of the provider.

If there is no active connection to a service provider, this property may attempt to infer the capabilities of a model based on the values of the **Provider** and **ModelName** properties. If the model name is recognized, the control will return the inferred capabilities associated with that model. If the model name is not recognized, this property will return zero (**llmModelFlagNone**).

Because capability information may be incomplete or inferred, applications should treat these flags as guidance rather than absolute guarantees of behavior. The provider ultimately determines which features are supported and how they are implemented.

The value returned by this property is a bitmask and may contain multiple flags combined using a bitwise **Or** operation. If no capabilities are defined or available for the model, the property will return zero. In practice, most supported models provide at least basic conversational capabilities, so a value of zero is uncommon and typically indicates that capability information is not available or could not be determined.

In some cases, capability information may be incomplete or inferred. If necessary, applications can override the detected capabilities by changing this property value. This can be useful when working with providers or models that require specific options which are not automatically detected. In general, applications should rely on the default capability detection unless a specific compatibility issue is encountered.

If necessary, applications can override the detected capabilities for the current model by setting this property. This can be useful when working with providers or models that require specific options which are not automatically detected. In general, applications should rely on the default capability detection unless a specific compatibility issue is encountered. Incorrect capability flags may cause requests to fail or result in undefined provider behavior.

Some flags may be reserved for internal use or represent provider-specific capabilities. Applications should not rely on undocumented flag values and should only test for defined constants.

Data Type

Integer (Int32)

Example

```
LlmClient1.ProviderName = "OpenAI"  
LlmClient1.ModelName = "gpt-5.4-nano"  
  
If (LlmClient1.ModelFlags And llmModelFlagReasoning) <> 0 Then  
    MsgBox "This model supports reasoning."  
End If
```

See Also

[ContextSize Property](#), [ModelName Property](#), [Provider Property](#), [ProviderName Property](#), [GetFirstModel Method](#), [GetNextModel Method](#)

ModelName Property

Sets or returns the name of the current model used for requests.

Syntax

`object.ModelName [= value ]`

Remarks

The **ModelName** property returns the name of the current model. If this property is changed while there is an active connection, it changes the model associated with the client session. Subsequent requests will use the new model and the client session does not need to be disconnected and reconnected.

The specified model name must be supported by the current provider. When the model name is changed, the internal model flags are reset to the default flags associated with the new model. If your application previously changed the model flags by setting the **ModelFlags** property, those flags must be set again after changing this property value.

The control does not attempt to resolve provider-specific aliases. For example, "gpt-5-mini" and "gpt-5.4-mini" would be considered different model names even if the provider considers them equivalent or aliases for the same underlying model.

If you set the value of this property to an empty string, the **ModelName** and **ModelFlags** properties will revert to the default values for the provider specified by the **Provider** property. If the current provider does not define a default model, this may result in an error indicating that a model name is required.

Changing the model name does not modify or clear the current message history. However, if conversation history is enabled, previous prompts and responses may still be included with subsequent requests sent to the new model. Because different models may interpret context differently, applications should consider calling **ClearHistory** after changing models unless preserving the existing conversation history is intentional.

Data Type

String

See Also

[DefaultModel Property](#), [HistorySize Property](#), [ModelFlags Property](#), [Provider Property](#), [ProviderName Property](#), [ClearHistory Method](#), [Connect Method](#)

Options Property

Returns or sets the connection and session options used by the control.

Syntax

object.Options [= *value*]

Remarks

The **Options** property is an Integer value which specifies one or more option flags. The property value is created by combining one or more of the following values using a bitwise **Or** operation:

Constant	Value	Description
IlmOptionNone	0	A standard connection to the server is established using the default behavior for the selected provider. No additional options are enabled, and the connection will use the provider's default protocol, caching behavior, and request headers.
IlmOptionNoCache	&H1	Disables provider and model metadata caching for the client session. When this option is specified, the control will not reuse cached metadata, and provider or model information will be retrieved from the server each time it is required. This may be useful when testing or when current data is required.
IlmOptionKeepAlive	&H2	Enables persistent HTTP connections using the keep-alive mechanism. When enabled, the underlying HTTP connection may be reused for multiple requests, reducing connection overhead and improving performance. If this option is not specified, the connection may be closed after each request.
IlmOptionProxy	&H8	Specifies that the connection should be made using the current Windows proxy server configuration. If the user does not have a proxy server configuration, this option is ignored. This option is typically used in environments where direct internet access is restricted.
IlmOptionNoUserAgent	&H20	Prevents the control from sending a User-Agent header with requests to the provider. By default, a User-Agent string is included to identify the client. This option may be used when a provider does not require a User-Agent header.
IlmOptionSecure	&H1000	Forces the use of a secure HTTPS connection when communicating with the provider. If the specified base URL or provider default would

		normally use an insecure protocol, the connection will be upgraded to HTTPS. Connections to providers such as OpenAI, Google and Anthropic will always use secure connections.
<code>llmOptionDefault</code>	<code>llmOptionNone</code>	Specifies the default option set, which is equivalent to <code>llmOptionNone</code> . No additional flags are enabled and the connection uses standard behavior.

Setting the **Options** property changes the current option flags for the current client session. These flags control how the client establishes connections and sends requests to the service provider. Applications should use care when changing options that affect the underlying connection, such as **`llmOptionSecure`** or **`llmOptionProxy`**. Changing these options while there is an active connection may result in unexpected errors. The client may need to establish a new connection using updated settings.

The **`llmOptionSecure`** option forces the client to use HTTPS when communicating with the provider. This is appropriate for public API providers, but may not be supported by locally hosted providers such as LM Studio or Ollama. Attempting to force a secure connection to a provider that does not support HTTPS will cause the connection to fail.

The **`llmOptionProxy`** option causes the client to use the configured Windows proxy settings when connecting to the provider. This may be required in managed or corporate network environments, but should generally only be enabled when proxy support is actually required.

The **`llmOptionNoUserAgent`** option does not make requests anonymously. The provider may still identify the client based on authentication credentials, IP address information, request patterns, or other HTTP headers included with the request. For more information, refer to the **UserAgent** property.

Setting or clearing the **`llmOptionNoCache`** option changes whether provider and model metadata may be cached. Applications can also set the **CacheTime** property to control caching behavior.

Data Type

Integer (Int32)

See Also

[BaseUrl Property](#), [CacheTime Property](#), [IdleTime Property](#), [KeepAlive Property](#), [Secure Property](#), [Timeout Property](#), [UserAgent Property](#), [Connect Method](#)

OrganizationId Property

Sets and returns the organization or tenant identifier that may be used by the selected provider.

Syntax

`object.OrganizationId [= value ]`

Remarks

The **OrganizationId** property specifies an optional organization, tenant or account identifier used by some providers when processing requests. The value of this property is included with requests when supported by the selected provider.

This property is primarily intended for enterprise or multi-tenant environments where a provider account may be associated with multiple organizations or projects. Most applications will not need to set this property unless specifically required by the provider. If the current provider does not support organization identifiers, the value is ignored.

Data Type

String

See Also

[ApiKey Property](#), [ApiVersion Property](#), [ModelName Property](#), [ProjectId Property](#), [Provider Property](#), [UserId Property](#)

OutputTokens Property

Returns the number of output tokens generated by the most recent response.

Syntax

object.OutputTokens

Remarks

The **OutputTokens** property returns the number of output tokens generated by the most recent response received from the provider. Output tokens represent the content generated by the model, including text, reasoning content and other generated data returned as part of the response.

Output token usage is typically reported by the provider as part of the response metadata. If token usage information is not available, the property value may be zero.

Generated output tokens are included when calculating usage limits and billing costs for most providers. Applications which generate long responses or use reasoning-oriented models may consume significantly more output tokens than expected.

To determine the estimated number of tokens currently used by the conversation history, check the value of the **ContextUsed** property.

Data Type

Integer (Int32)

See Also

[ContextUsed Property](#), [InputTokens Property](#), [MaxTokens Property](#), [TotalTokens Property](#), [SendMessage Method](#)

ProjectId Property

Sets and returns a project identifier used by providers that support project-based authentication or resource management.

Syntax

object.**ProjectId** [= *value*]

Remarks

The **ProjectId** property specifies an optional project identifier used by some providers when processing requests. The value of this property is included with requests when supported by the selected provider.

This property is primarily intended for providers which support project-based authentication, billing or resource management. Most applications will not need to set this property unless specifically required by the provider or account configuration. If the current provider does not support project identifiers, the value is ignored.

Data Type

String

See Also

[ApiKey Property](#), [ApiVersion Property](#), [ModelName Property](#), [OrganizationId Property](#), [Provider Property](#), [UserId Property](#)

Prompt Property

Sets or returns the most recent prompt sent to the current model.

Syntax

`object.Prompt [= value ]`

Remarks

The **Prompt** property specifies the message text which will be sent to the model when the **SendMessage** method is called. After a request has completed, this property returns the most recent prompt sent by the control.

Setting this property does not automatically send a request to the provider. Applications must call the **Ask** or **SendMessage** method after assigning a prompt value. Although this property may be assigned an empty string or a string which contains only whitespace, these methods will reject prompts which do not contain any text.

An application which accepts prompts provided by a user should apply appropriate validation, filtering or normalization before sending requests to the service provider. The **ValidateText** method verifies that the prompt contains valid message text and the **NormalizeText** method can be used to normalize text formatting.

The validation and normalization methods do not perform any semantic analysis of the prompt and do not provide protection against malicious or intentionally misleading input. It is the responsibility of the application to ensure that user-provided input is appropriate for its intended use. This includes considering scenarios where input may attempt to override instructions, inject unintended prompts or otherwise influence the behavior of the model.

Data Type

String

See Also

[Response Property](#), [SystemPrompt Property](#), [Ask Method](#), [NormalizeText Method](#), [SendMessage Method](#), [ValidateText Method](#)

Provider Property

Sets or returns the identifier for the current service provider.

Syntax

`object.Provider [= value ]`

Remarks

The **Provider** property returns a numeric identifier for the current provider. If no provider has been selected, this property returns zero. Changing this property selects the provider used for inference. This is used with the **ModelName** property to specify the service and model the client will use. This property cannot be changed while there is an active connection to a service provider.

Constant	Value	Description
<code>llmProviderNone</code>	0	No provider specified.
<code>llmProviderLocal</code>	1	Local inference provider, such as LM Studio or Ollama.
<code>llmProviderOpenAI</code>	2	OpenAI provider using the ChatGPT models.
<code>llmProviderAnthropic</code>	3	Anthropic provider using the Claude models.
<code>llmProviderGoogle</code>	4	Google AI provider using the Gemini models.
<code>llmProviderMicrosoft</code>	5	Microsoft Azure AI Foundry provider using OpenAI-compatible models.
<code>llmProviderMistral</code>	6	Mistral AI provider using the Mistral models.

The provider identifiers are predefined values used by the control to select an internal provider definition. In some cases, applications may be able to use a compatible provider by selecting the provider whose API format it supports, and then setting the **BaseUrl** and **ModelName** properties to the appropriate values. For example, a provider which implements an OpenAI-compatible API may be used by selecting `llmProviderOpenAI` and specifying the provider's endpoint and model name.

The **Provider** and **ProviderName** properties are reciprocal. Changing the value of one property automatically changes the value of the other.

Changing the current provider also resets the **ModelName** and **ModelFlags** properties to the default model for the selected provider, and resets the **BaseUrl** property to the default endpoint for that provider. Applications should always set the provider identifier first, and then change the model name or endpoint URL if necessary.

Setting this property to `llmProviderNone` clears the values of the **BaseUrl**, **ModelName** and **ModelFlags** properties.

Data Type

Integer (Int32)

Example

```
' Select the OpenAI provider
llmClient1.Provider = llmProviderOpenAI
llmClient1.ModelName = "gpt-5.4-nano"
llmClient1.ApiKey = "%OPENAI_API_KEY%"
```

```
If LlmClient1.Connect() Then
    LlmClient1.Prompt = "What is the capital of Denmark?"

    If LlmClient1.SendMessage() Then
        MsgBox LlmClient1.Response, vbInformation
    Else
        MsgBox LlmClient1.LastErrorString, vbExclamation
    End If

    LlmClient1.Disconnect
Else
    MsgBox LlmClient1.LastErrorString, vbExclamation
End If
```

See Also

[BaseUrl Property](#), [DefaultModel Property](#), [IsLocal Property](#), [ModelFlags Property](#), [ModelName Property](#), [ProviderFlags Property](#), [ProviderName Property](#), [Connect Method](#), [GetProvider Method](#)

ProviderFlags Property

Returns the capability and requirement flags supported by the current provider.

Syntax

object.ProviderFlags

Remarks

The **ProviderFlags** property returns the capability flags associated with the current provider. These flags describe the features and requirements supported by the provider, such as whether authentication is required or if model enumeration is available. The flags are informational only and the flags assigned to a provider cannot be changed by the application.

Constant	Value	Description
IlmProviderFlagNone	0	No provider requirements specified.
IlmProviderFlagRequireTls	&H1	Requires a secure TLS (HTTPS) connection.
IlmProviderFlagRequireAuth	&H2	Requires authentication (e.g., API key or token).
IlmProviderFlagApiVersion	&H4	Requires an explicit API version parameter.
IlmProviderFlagLocal	&H8	Locally hosted provider such as LM Studio or Ollama.
IlmProviderFlagModelList	&H10	Supports enumerating available models.
IlmProviderFlagModelInfo	&H20	Supports retrieving detailed model information.

Changing the value of the **Provider** or **ProviderName** property changes the provider associated with the current session and may change the flags returned by this property.

Data Type

Integer (Int32)

See Also

[ApiKey Property](#), [ApiVersion Property](#), [IsLocal Property](#), [Provider Property](#), [ProviderName Property](#), [Connect Method](#), [GetProvider Method](#)

ProviderName Property

Sets or returns the name of the current service provider.

Syntax

`object.ProviderName [= value ]`

Remarks

The **ProviderName** property returns a String which identifies the current provider. If no provider has been selected, this property returns an empty string. Changing this property selects the provider used for inference. This is used with the **ModelName** property to specify the service and model the client will use. This property cannot be changed while there is an active connection to a service provider.

Name	Constant	Description
Local	llmProviderLocal	Local inference provider, such as LM Studio or Ollama.
OpenAI	llmProviderOpenAI	OpenAI provider using the ChatGPT models.
Anthropic	llmProviderAnthropic	Anthropic provider using the Claude models.
Google	llmProviderGoogle	Google AI provider using the Gemini models.
Microsoft	llmProviderMicrosoft	Microsoft Foundry provider using OpenAI-compatible models.
Mistral	llmProviderMistral	Mistral AI provider using the Mistral models.

The provider names listed above are predefined values used by the control to select an internal provider definition. In some cases, applications may be able to use a compatible provider by selecting the provider whose API format it supports, and then setting the **BaseUrl** and **ModelName** properties to the appropriate values. For example, a provider which implements an OpenAI-compatible API may be used by setting this property to **"OpenAI"** and specifying the provider's endpoint and model name.

The **ProviderName** property can be used to display a human-readable provider name to a user, or as an alternative to assigning a numeric identifier to the **Provider** property. If the application assigns a value to this property, it is compared against an internal table of matching names to determine the appropriate provider. The comparison is not case-sensitive, and matches do not have to be exact. For example, if the string "Microsoft Foundry" were assigned to this property, it would recognize the provider as **llmProviderMicrosoft**.

If the specified provider name is not recognized, assigning a value to this property will fail and the control will return an invalid provider error. Assigning an empty string to this property is the same as setting the **Provider** property to **llmProviderNone**.

The **ProviderName** and **Provider** properties are reciprocal. Changing the value of one property automatically changes the value of the other.

Changing the current provider also resets the **ModelName** and **ModelFlags** properties to the default model for the selected provider, and resets the **BaseUrl** property to the default endpoint for that provider. Applications should always set the provider name first, and then change the model name or endpoint URL if necessary.

Setting this property to an empty string clears the values of the **BaseUrl**, **ModelName** and **ModelFlags** properties.

Data Type

String

Example

```
' Select the OpenAI provider
LlmClient1.ProviderName = "OpenAI"
LlmClient1.ModelName = "gpt-5.4-nano"
LlmClient1.ApiKey = "%OPENAI_API_KEY%"

If LlmClient1.Connect() Then
    LlmClient1.Prompt = "What is the capital of Denmark?"

    If LlmClient1.SendMessage() Then
        MsgBox LlmClient1.Response, vbInformation
    Else
        MsgBox LlmClient1.LastErrorString, vbExclamation
    End If

    LlmClient1.Disconnect
Else
    MsgBox LlmClient1.LastErrorString, vbExclamation
End If
```

See Also

ReasoningLevel Property

Sets or returns the preferred reasoning effort level used for models that support reasoning.

Syntax

`object.ReasoningLevel [= value ]`

Remarks

The **ReasoningLevel** property specifies the preferred reasoning effort level used for requests sent to models which support reasoning-oriented generation. Higher reasoning levels may improve response quality for complex prompts, but can also increase response time and token usage.

Constant	Value	Description
llmReasoningNone	0	No reasoning, even if it is available.
llmReasoningDefault	1	Provider or model default.
llmReasoningLow	2	Prefer faster responses; reduces usage costs.
llmReasoningMedium	3	Balanced reasoning.
llmReasoningHigh	4	Prefer quality responses; increases usage costs.
llmReasoningMaximum	5	Maximum reasoning quality.

Reasoning support and available reasoning levels depend on the selected provider and model. Some providers may ignore this property, map the requested value to a provider-specific setting, or support only a subset of the available reasoning levels. The default value is **llmReasoningDefault**, which allows the provider or model to select the appropriate reasoning behavior.

This property returns the currently selected reasoning preference. The returned value does not guarantee that the selected provider or model supports the requested reasoning level.

Data Type

Integer (Int32)

See Also

[InputTokens Property](#), [MaxTokens Property](#), [ModelFlags Property](#), [OutputTokens Property](#), [Temperature Property](#), [TotalTokens Property](#), [SendMessage Method](#)

Response Property

Returns the response to the most recent message prompt sent to the model.

Syntax

object.Response

Remarks

The **Response** property returns the most recent response from the model. If no messages have been sent, this property will return an empty string. Clearing the client history will not affect the value of this property. The control always retains the most recent prompt and response for the session.

Responses from a model which contain isolated line feed or carriage return characters are normalized to the standard Windows CRLF end-of-line sequence. This ensures consistent formatting across different providers and improves compatibility with Windows controls and user interface components.

Model responses may include Markdown formatting such as headings, lists, or code blocks. Applications are responsible for handling or filtering this formatting as appropriate. If plain text output is preferred, the application can provide a system prompt requesting the model to return plain text responses only.

The message prompt and response text returned by this property may contain Unicode characters, including international text, accented characters, symbols, or emoji characters. Internally, the control stores text as Unicode using UTF-8 encoding, and most modern development environments and controls will display these characters correctly. However, older development tools such as Visual Basic 6 and some legacy Windows common controls may not fully support Unicode text. Characters that are not available in the current system code page may appear incorrectly, be replaced with placeholder characters, or display as question marks.

The standard Visual Basic controls such as **Label1** and **TextBox** have limited support displaying Unicode characters, especially those outside the Basic Multilingual Plane (such as emoji or mathematical symbols). These controls attempt to convert Unicode strings to ANSI using the system locale, which can result in garbled or missing characters. To correctly display full Unicode text, you must use controls that support Unicode natively, such as those in the Microsoft Forms 2.0 Object Library (FM20.DLL), with appropriate font settings.

Data Type

String

Example

```
' Send a simple prompt to the model and update a multi-line
' TextBox control with the response
LlmClient1.Prompt = "What is the capital of Denmark?"

If LlmClient1.SendMessage() Then
    txtResponse.Text = LlmClient1.Response
Else
    MsgBox LlmClient1.LastErrorString, vbExclamation
End If
```

See Also

[MessageId Property](#), [Prompt Property](#), [ResponseModel Property](#), [GetFirstMessage Method](#), [GetMessage Method](#), [GetNextMessage Method](#)

ResponseId Property

Returns the provider-assigned identifier for the most recent response.

Syntax

object.ResponseId

Remarks

The **ResponseId** property returns the identifier associated with the most recent response received from the provider. This value is assigned by the provider and is typically included in the response metadata returned by the service.

The format and meaning of the response identifier are provider-specific and may vary between providers or models. Applications should treat this value as an opaque string and should not depend on a specific format or naming convention. If the provider does not include a response identifier in the response metadata, this property returns an empty string.

Data Type

String

See Also

[MessageId Property](#), [Prompt Property](#), [Response Property](#), [ResponseModel Property](#), [ResponseStatus Property](#), [SendMessage Method](#)

ResponseModel Property

Returns the model name reported by the provider for the most recent response.

Syntax

object.ResponseModel

Remarks

The **ResponseModel** property returns the model name reported by the provider for the most recent response. This value is taken directly from the response metadata returned by the provider.

The model name returned by this property may differ from the value of the **ModelName** property used when the request was sent. Some providers may internally map model aliases to different model versions, redirect requests to updated models, or return a more specific model identifier than the one originally requested by the application.

Applications should treat this value as informational. The format and naming conventions used for model identifiers are provider-specific and may change over time. If the provider does not include a model name in the response metadata, this property returns an empty string.

Data Type

String

See Also

[DefaultModel Property](#), [ModelFlags Property](#), [ModelName Property](#), [Prompt Property](#), [Response Property](#), [ResponseId Property](#), [SendMessage Method](#)

ResponseStatus Property

Returns the completion status for the most recent response.

Syntax

object.ResponseStatus

Remarks

The **ResponseStatus** property indicates how the most recent request completed. This value describes the completion state of the response returned by the model and is independent of the HTTP status returned by the provider.

For example, a request may return a successful HTTP status while the response itself is incomplete, truncated due to token limits, or cancelled before generation completed. The **HttpStatus** property returns the HTTP response status from the provider, while the **ResponseStatus** property describes the state of the generated response.

This property can return one of the following values:

Constant	Value	Description
IlmResponseUnknown	0	No completion reason was specified by the provider or the response state was not recognized.
IlmResponseComplete	1	The response completed normally without interruption.
IlmResponseLimited	2	The response was truncated because a token limit or context limit was reached.
IlmResponseAborted	3	The request was cancelled, interrupted or terminated before the response completed.
IlmResponseError	4	An error occurred while processing the request or generating the response.
IlmResponseTimeout	5	The request exceeded the configured timeout period.

A value of **IlmResponseComplete** indicates that the response was generated normally. Other values may indicate that the response was truncated due to token limits, interrupted, cancelled, timed out or terminated because of an error. Applications can use this property to determine whether the generated response is complete before processing the returned content.

Data Type

Integer (Int32)

See Also

[ElapsedTime Property](#), [HttpStatus Property](#), [LastError Property](#), [LastErrorString Property](#), [Response Property](#), [ResponseId Property](#), [ResponseStatus Property](#), [Timeout Property](#), [SendMessage Method](#)

Secure Property

Sets or returns whether secure HTTPS connections are required.

Syntax

object.Secure [= { True | False }]

Remarks

The **Secure** property specifies whether the control should require the use of a secure HTTPS connection when communicating with the provider. When this property is **True**, the control will only connect using secure HTTPS connections.

The default value of this property is **False**. However, this does not prevent the control from using secure connections. Most cloud-based providers require HTTPS connections and the control will automatically use a secure connection when required by the selected provider.

This property is primarily useful when working with locally hosted providers such as LM Studio or Ollama, where both secure and insecure connections may be available. Setting this property to **True** forces the client to use HTTPS even when the provider does not explicitly require it. If the provider or endpoint does not support secure connections, attempts to connect with this property enabled will fail.

Secure connections use TLS encryption provided by the Windows Schannel security provider, including support for strong encryption algorithms such as AES-256 when available. On modern Windows platforms, the control will use TLS 1.3 connections when available and fall back to TLS 1.2 on older systems which do not support newer protocol versions.

Data Type

Boolean

See Also

[Options Property](#), [ProviderFlags Property](#), [Connect Method](#)

SystemPrompt Property

Sets or returns the system prompt used to provide instructions for the model.

Syntax

`object.SystemPrompt [= value ]`

Remarks

The **SystemPrompt** property returns the current system prompt. If a system prompt has not been specified, this property will return an empty string. Changing the value of this property will change the system prompt included with subsequent messages sent to the model.

A system prompt provides instructions that are included with each request sent to the model. It can be used to define the expected role, tone, response style, formatting rules, or other application-specific guidance that should apply to the session. For example, an application might use a system prompt to request short responses, avoid Markdown formatting, return structured text, or answer only within the context of a specific feature or workflow.

Because conversation history is included with each request, messages generated using a previous system prompt may still influence subsequent responses. Changing or clearing the system prompt only affects future requests and does not retroactively modify existing messages in the history. If the new prompt represents a significant change in behavior, applications may want to call **ClearHistory** before sending additional messages.

The system prompt should be treated as guidance, not a guarantee. Different providers and models may interpret system instructions differently, and user messages may still influence the response. Setting this property to an empty string will clear the current system prompt and subsequent requests will not include a system prompt.

Support for system prompts may vary between providers and models. Some providers treat the system prompt as a distinct message role, while others incorporate it as part of a separate instruction field. The control will map the system prompt to the appropriate format for the selected provider, but the exact behavior and influence on the response may differ. Applications should test system prompt behavior with their selected provider to ensure it produces the desired results.

Some providers and models may not support a dedicated system role. This is more common with locally hosted models using applications such as LM Studio or Ollama. To determine if a model supports system prompts, check the value of the **ModelFlags** property for the `11mModelFlagSystemRole` flag.

Data Type

String

See Also

[ModelFlags Property](#), [Prompt Property](#), [Response Property](#), [ClearHistory Method](#), [SendMessage Method](#)

Temperature Property

Sets or returns the sampling temperature used to control response variability.

Syntax

object.Temperature [= *value*]

Remarks

The **Temperature** property returns or changes the sampling temperature used when generating responses from the current model. Temperature controls the amount of randomness used when selecting tokens during text generation. Lower values generally produce more predictable and consistent responses, while higher values can produce more varied and creative output.

A temperature value of 0.0 requests the most deterministic response possible from the model. This is typically recommended for tasks that require stable or structured output, such as code generation, classification, data extraction, or responses that must follow a specific format. Higher values, such as 1.0 or above, may produce more diverse wording, alternative phrasing, or creative responses, but can also increase the likelihood of inconsistent or inaccurate output.

Most providers support temperature values in the range of 0.0 to 2.0, although the exact supported range and behavior may vary between providers and models. Some models may ignore this property entirely or internally restrict the range of accepted values. If an unsupported value is specified, the provider may clamp the value to a supported range or reject the request.

Changing the temperature only affects subsequent requests and does not modify existing messages or responses stored in the conversation history.

In most cases, applications should adjust only the temperature setting and leave advanced sampling parameters such as **TopP** and **TopK** at their default values unless the application has specific requirements and understands how those settings affect model behavior.

The default temperature value depends on the selected provider and model. Some providers may use different default values for reasoning models, coding models, or creative writing models.

Data Type

Double

See Also

[ReasoningLevel Property](#), [TopK Property](#), [TopP Property](#)

ThrowError Property

Enables or disables error handling by the application.

Syntax

object.ThrowError = { True | False }

Remarks

Error handling for methods can be performed using either return codes or exceptions, depending on the value of this property.

If the **ThrowError** property is set to False, methods will return a status value indicating success or failure. Applications should check the return value of each method and use the **LastError** and **LastErrorString** properties to determine the cause of any error.

If the **ThrowError** property is set to True, errors occurring within the control will be raised to the host application as ActiveX exceptions. In addition, the **OnError** event will fire. This allows applications to use language-specific exception handling mechanisms, such as Visual Basic error handling, instead of checking individual return values after each method call.

Even when the **ThrowError** property is set to True, the **LastError** and **LastErrorString** properties will still be updated with information about the most recent error.

If an error occurs while accessing a property value, an exception will be raised regardless of the value of the **ThrowError** property. However, the **OnError** event will not be fired for property access errors.

Data Type

Boolean

Example

The following example handles errors by checking the return code of a method:

```
LlmClient1.ThrowError = False

If LlmClient1.Connect() Then
    MsgBox "Connected to " & LlmClient1.ProviderName
Else
    MsgBox LlmClient1.LastErrorString, vbExclamation
    Exit Sub
Endif
```

The following example handles errors by throwing them to the container:

```
On Error Resume Next: Err.Clear
LlmClient1.ThrowError = True

LlmClient1.Connect

If Err.Number <> 0
    MsgBox Err.Description, vbExclamation
    Exit Sub
End If

On Error GoTo 0
```

See Also

Timeout Property

Sets or returns the maximum number of seconds to wait for a request to complete.

Syntax

object.Timeout [= *seconds*]

Remarks

The **Timeout** property specifies the maximum number of seconds the control will wait for a connection or request to complete before returning an error.

This property determines how long the control will attempt to establish a connection when using the **Connect** method. If a connection cannot be established within the specified time period, the operation will fail and return an error.

This property also determines how long the control will wait for a response after submitting a message prompt using the **Ask** or **SendMessage** method. If the provider does not return a response within the specified time period, the request will fail and the control will report a timeout error.

Some models, particularly reasoning-oriented models or models generating lengthy responses, may require significantly more time to complete a request than traditional web service operations. Applications should avoid setting excessively short timeout values when communicating with cloud-based providers or locally hosted models running on slower hardware.

Changing the value of this property affects subsequent operations and does not modify requests that are already in progress.

Data Type

Integer (Int32)

See Also

[Ask Method](#), [Connect Method](#), [SendMessage Method](#)

Timestamp Property

Returns the date and time the last response was received.

Syntax

object.Timestamp

Remarks

The **Timestamp** property returns the local date and time the most recent response was received from the provider. The value is formatted using the current user's regional date and time settings.

This property is updated after a successful call to the **Ask** or **SendMessage** method. If no response has been received, this property will return an empty string.

The timestamp represents when the response was received by the control, not necessarily when the response was generated by the provider. Some providers may also include their own internal timestamps as part of the response metadata, but those values are not returned by this property.

Because the value returned by this property is formatted using the current user's locale settings, the exact format of the date and time string may vary between systems. Applications that require locale-independent date and time handling should store or convert the value using an appropriate date and time format.

This property only reflects the timestamp associated with the most recent response. Applications can retrieve timestamp values for messages stored in the conversation history by using the **GetFirstMessage**, **GetNextMessage** or **GetMessage** methods.

Data Type

String

Example

```
Dim strResponse As String
Dim dtResponse As Date

strResponse = LlmClient1.Ask("What is the capital of Denmark?")
If Len(strResponse) > 0 Then
    ' Display the message timestamp using a custom format
    dtResponse = CDate(LlmClient1.Timestamp)
    MsgBox Format$(dtResponse, "yyyy-mm-dd hh:nn:ss"), vbInformation
End If
```

See Also

[ElapsedTime Property](#), [MessageId Property](#), [Response Property](#), [Ask Method](#), [GetFirstMessage Method](#), [GetMessage Method](#), [GetNextMessage Method](#), [SendMessage Method](#)

TotalTokens Property

Returns the total number of tokens used by the most recent request and response.

Syntax

object.TotalTokens

Remarks

The **TotalTokens** property returns the total number of tokens used by the most recent request and response. This value includes both the input tokens associated with the prompt and conversation history, and the output tokens generated by the model.

This property is updated after a successful call to the **Ask** or **SendMessage** method. If token usage information is not available, this property will return zero. The value returned by this property is equivalent to the sum of the **InputTokens** and **OutputTokens** properties.

Token usage is reported by the provider when available. Some providers or locally hosted models may not return precise token usage information, particularly when using older models or third-party inference servers. In those cases, the values returned by this property may be estimated or unavailable.

Tokens do not directly correspond to characters or words, but as a general approximation, one token represents about 3-4 English characters. The exact number of tokens depends on the language, formatting, and content being processed.

Applications can use token usage information to estimate usage costs, monitor context usage, or help determine appropriate **MaxTokens** and **HistorySize** settings for a session.

Data Type

Integer (Int32)

See Also

[ContextSize Property](#), [ContextUsed Property](#), [HistorySize Property](#), [InputTokens Property](#), [MaxTokens Property](#), [OutputTokens Property](#), [EstimateTokens Method](#)

TopK Property

Sets or returns the top-k sampling value used by providers and models that support it.

Syntax

`object.TopK [= value ]`

Remarks

The **TopK** property returns or changes the top-k sampling value used when generating responses from the current model. Top-k sampling limits token selection to the most likely candidate tokens during text generation.

When a top-k value is specified, the model considers only the most probable *k* tokens at each step of generation before selecting the next token. Lower values generally produce more deterministic and focused output, while higher values allow more variation and diversity in generated responses.

A value of zero typically indicates that top-k sampling is disabled or that the provider should use its default behavior. The exact interpretation of this value may vary between providers and models.

Support for top-k sampling varies significantly between providers and models. Many providers either ignore this setting entirely or use provider-specific defaults that cannot be overridden. Some providers may also restrict the valid range of values or silently clamp values to supported limits.

In most cases, applications should adjust only the **Temperature** property and leave advanced sampling parameters such as **TopK** and **TopP** at their default values unless the application has specific requirements and understands how those settings affect model behavior.

Changing the value of this property only affects subsequent requests and does not modify existing messages or responses stored in the conversation history.

Data Type

Integer (Int32)

See Also

[Temperature Property](#), [TopP Property](#)

TopP Property

Sets or returns the nucleus sampling value used to control token selection.

Syntax

object.**TopP** [= *value*]

Remarks

The **TopP** property returns or changes the nucleus sampling value used when generating responses from the current model. Nucleus sampling limits token selection to a subset of the most probable tokens whose combined probability is less than or equal to the specified value.

Lower values generally produce more focused and deterministic responses by restricting token selection to a smaller set of highly probable tokens. Higher values allow a broader range of token choices and may produce more varied or creative responses.

Typical values range from 0.0 to 1.0. A value of 1.0 usually indicates that nucleus sampling restrictions are disabled and the provider should use the full probability distribution when selecting tokens. The exact interpretation of this value may vary between providers and models.

Support for nucleus sampling varies between providers and models. Some providers may ignore this property entirely, use internal defaults that cannot be overridden, or silently clamp values to a supported range.

In most cases, applications should adjust only the **Temperature** property and leave advanced sampling parameters such as **TopP** and **TopK** at their default values unless the application has specific requirements and understands how those settings affect model behavior.

Changing the value of this property only affects subsequent requests and does not modify existing messages or responses stored in the conversation history.

Data Type

Double

See Also

[Temperature Property](#), [TopK Property](#)

Trace Property

Enables or disables network function level logging.

Syntax

`object.Trace [= { True | False } ]`

Remarks

The **Trace** property is used to enable or disable the logging of network function calls. When enabled, each network function call is logged to a file, including the function parameters, return value and error code if applicable. This facility can be enabled and disabled at run time, and the trace log file can be specified by setting the **TraceFile** property. All function calls that are being logged are appended to the trace file, if it exists. If no log file exists when tracing is enabled, the file is created.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

Data Type

Boolean

See Also

[TraceFile Property](#), [TraceFlags Property](#)

TraceFile Property

Sets and returns the name of the file to use when logging network function calls.

Syntax

object.TraceFile [= *filename*]

Remarks

The **TraceFile** property is used to specify the name of the file that is created when logging is enabled. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

If the file exists, the output is appended to the file, otherwise the file is created. Since logging is enabled per-process, the log file is shared by all instances of the controls being used. If you create multiple instances of the control, you only need to enable logging for a single instance. Because log files can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as Integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "0x". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxx:xxxx:xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, the control is attempting to connect to a system with the IPv4 address 192.0.0.1 on port 1234.

If the log file cannot be created, or the user does not have permission to modify an existing file, the error is silently ignored and no output will be generated.

Data Type

String

See Also

[Trace Property](#), [TraceFlags Property](#)

TraceFlags Property

Gets and sets the network function logging flags.

Syntax

object.TraceFlags [= *flags*]

Remarks

The **TraceFlags** property is used to specify the type of information included when network logging is enabled. The following values may be used:

Constant	Value	Description
llmTraceInfo	0	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
llmTraceError	&H0001	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
llmTraceWarning	&H0002	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
llmTraceHexDump	&H0004	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
llmTraceTruncate	&H0008	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.

Since logging is enabled per-process, the trace flags are shared by all instances of the control being used. If multiple controls have tracing enabled, the **TraceFlags** property should be set to the same value for each control. Changing the trace flags for any one instance of the control will affect the logging performed for all other instances used by the application.

Warnings are generated when a non-fatal error is returned by a network function. For example, if data is being written through the control and an error indicating that the operation would block is returned,

only a warning is logged since the application simply needs to attempt to write the data at a later time.

Data Type

Integer (Int32)

See Also

[Trace Property](#), [TraceFile Property](#)

UserAgent Property

Sets or returns the user agent string sent with provider requests.

Syntax

`object.UserAgent [= value ]`

Remarks

The **UserAgent** property returns or changes the user agent string included with HTTP requests sent to the current provider. User agent strings are commonly used to identify the client application, library, operating system, or application version associated with a request.

If this property is not explicitly set, the control will use a default user agent string that identifies the Windows platform, operating system version and SocketTools version. Applications may specify a custom user-agent string to identify their application when communicating with a provider. Some providers may use the user-agent string for logging, diagnostics, analytics, compatibility checks, or rate limiting. Certain providers may reject requests that do not include a valid user agent string.

If the **ApplicationName** property has been set, that value will also be included in the user-agent string sent to the server.

Changing the value of this property affects subsequent requests and does not modify requests that are already in progress. Applications should avoid including sensitive or personally identifiable information in the user-agent string because it may be recorded in provider logs or diagnostic systems.

If the **11mOptionNoUserAgent** option flag is specified in the **Options** property, the control will not include a user-agent header with requests, regardless of the value of this property.

You should only change this property value when necessary. Removing or changing the user-agent string does not make requests anonymous. Providers may still identify requests using other information such as API keys, account identifiers, IP addresses, or other request metadata.

Data Type

String

See Also

[ApplicationName Property](#), [Options Property](#), [ProviderName Property](#), [Ask Method](#), [Connect Method](#), [SendMessage Method](#)

UserId Property

Sets or returns the provider-specific user identifier associated with requests.

Syntax

object.UserId [= *value*]

Remarks

The **UserId** property returns or changes the user identifier associated with requests sent to the current provider. If this property is set, the value will be included with requests using the provider's supported user identification field. Setting this property to an empty string disables inclusion of a user identifier with requests.

Some providers allow applications to specify a user identifier as part of the request payload for diagnostics, analytics, rate limiting, or request tracking. The control will map this value to the appropriate request field for the selected provider when supported. The interpretation and handling of this value is entirely provider-specific. Some providers may ignore the value, impose restrictions on its format or length, or use it only for internal monitoring and logging purposes.

Applications should avoid including sensitive or personally identifiable information in the user identifier value unless required by the provider. User identifier values may be stored in provider logs or retained for diagnostic and security purposes.

Changing the value of this property affects subsequent requests and does not modify requests that are already in progress.

Data Type

String

See Also

[ApiKey Property](#), [OrganizationId Property](#), [ProjectId Property](#), [ProviderName Property](#)

Version Property

Returns the current version of the ActiveX control.

Syntax

object.Version

Remarks

The **Version** property returns the current version of the control. This can be used by an application for validation purposes. The version returned is composed of four numbers, separated by periods. The first number is the major version number, the second number is the minor version number, the third is the build number and the fourth is the revision number.

Data Type

String

See Also

[Initialize Method](#)

LlmClient Control Methods

Method	Description
Ask	Sends a prompt to the current provider and returns a response.
Cancel	Cancels the current request if an operation is in progress.
ClearHeaders	Removes all custom request headers for the current session.
ClearHistory	Removes all messages and responses from the client history.
Connect	Connects to the selected provider using the specified model, credentials and connection options.
Disconnect	Disconnects from the current provider and closes the active session connection.
EstimateTokens	Returns an estimated token count for the specified message text.
ExportHistory	Exports messages from the client history to a file.
FindMessage	Searches the conversation history for a message or response that matches the specified text.
GetFirstMessage	Retrieves the first message and response from the client history.
GetFirstModel	Retrieves the first model available for the current provider.
GetHeader	Returns the value of a HTTP header from the server response.
GetMessage	Retrieves a specific message prompt and response from the client history using a message identifier.
GetNextMessage	Retrieves the next message and response from the client history.
GetNextModel	Retrieves the next model available for the current provider.
GetProvider	Returns information about a provider, including its names, endpoint, default model and flags.
ImportHistory	Imports message history from a file into the current client session.
Initialize	Initializes the control and optionally specifies a runtime license key.
NormalizeText	Normalizes message text by removing extraneous whitespace and applying consistent formatting
Reset	Resets the control to its default state and clears session-specific information.
SendMessage	Sends a prompt to the current model, returning the response and message identifier.
SetHeader	Sets a custom HTTP header value that to be included with new requests
TrimHistory	Removes older messages from the conversation history.
Uninitialize	Uninitializes the control and releases resources allocated by the current session.
ValidateModel	Validates a model name for the current provider.
ValidateText	Checks whether the specified message text is valid for use as a prompt.

Ask Method

Sends a prompt to the current model and returns the response as a String value.

Syntax

object.Ask([*Prompt*])

Parameters

Prompt

A String value which specifies the message prompt which should be sent to the current model. If the **Prompt** parameter is not specified, the method will use the current value of the **Prompt** property. A prompt cannot consist only of spaces and line break characters. If the prompt does not contain any text, the method will fail.

Return Value

If the method succeeds, the return value is a String which contains the response generated by the current model. If the method fails, the return value will be an empty string. Extended error information can be obtained using the **LastError** property.

Remarks

This method provides a simplified way to send a single prompt to a model and return the generated response. Unlike the **Connect**, **SendMessage** and **Disconnect** methods, this method manages the connection automatically and is intended for simple request and response operations.

If there is no active connection to a service provider, the method will establish a temporary connection using the current values of the **ProviderName**, **ModelName**, **BaseUrl** and **ApiKey** properties. After the response has been returned, the temporary connection will be closed automatically.

The value of the **Prompt** and **Response** properties will be updated when this method returns. See the **Response** property for additional information about text formatting and Unicode handling for model responses.

This method does not preserve conversation history between calls. Applications which require conversational context, persistent connections or advanced session management should use the **Connect**, **SendMessage** and **Disconnect** methods instead.

If the method succeeds but the model does not return any text, the return value will be an empty string and the **LastError** property will return zero.

Example

```
Dim strResponse As String

LlmClient1.ProviderName = "OpenAI"
LlmClient1.ModelName = "gpt-5.4-nano"
LlmClient1.ApiKey = "%OPENAI_API_KEY%"

strResponse = LlmClient1.Ask("How do you calculate the volume of a sphere?")

If Len(strResponse) > 0 Then
    MsgBox strResponse, vbInformation
Else
    If LlmClient1.LastError = 0 Then
        MsgBox "There was no response to this question", vbInformation
```

```
Else
    MsgBox LlmClient1.LastErrorString, vbExclamation
End If
End If
```

See Also

[ApiKey Property](#), [BaseUrl Property](#), [ModelName Property](#), [Prompt Property](#), [Provider Property](#), [ProviderName Property](#), [Response Property](#), [TotalTokens Property](#), [Connect Method](#), [SendMessage Method](#)

Cancel Method

Cancels the current blocking request.

Syntax

object.Cancel

Parameters

None.

Return Value

None.

Remarks

The **Cancel** method cancels the current blocking request by closing the active HTTP connection associated with the client session. This causes the blocking operation to fail and return control to the calling thread. The last error code for the blocking function will be set to indicate the operation was canceled.

This method cancels the request locally. It does not guarantee that the provider will stop processing a request that has already been received. The provider may still complete the request and may charge for any processing or tokens used before the connection was closed.

Canceling a request does not delete the client session or clear the conversation history. The client handle remains valid, and a new HTTP connection will be established automatically if it is needed for a subsequent request. If no blocking request is currently in progress, this method succeeds and has no effect.

See Also

[IsBlocked Property](#), [Reset Method](#), [SendMessage Method](#), [OnCancel Event](#)

ClearHeaders Method

Removes all custom request headers for the current session.

Syntax

object.ClearHeaders

Parameters

None.

Return Value

A value of **True** is returned if the method completed successfully. If the method fails, it will return **False** and the **LastError** property will contain the error code.

Remarks

The **ClearHeaders** method removes all custom request header values set using the **SetHeader** method. This is useful when you want to ensure that custom headers used for a previous call to **SendMessage** are not included with subsequent requests made during the same session.

This method does not clear authentication credentials, organization identifiers, project identifiers, or any required headers automatically generated by the control.

See Also

[ApiKey Property](#), [OrganizationId Property](#), [ProjectId Property](#), [GetHeader Method](#), [SendMessage Method](#), [SetHeader Method](#)

ClearHistory Method

The **ClearHistory** method clears the conversation history for the current client session.

Syntax

object.ClearHistory

Parameters

None.

Return Value

A value of **True** is returned if the method succeeds. If the method fails, it will return **False** and the **LastError** property will contain the error code.

Remarks

The **ClearHistory** method removes all messages and responses stored in the conversation history for the specified client session. This can be used to begin a new conversation while preserving the current connection, provider settings, model selection, timeout, system prompt and other session options.

This method only clears the local history maintained by the client. It does not reset provider-specific settings, delete cached model information or close the active HTTP connection. It also does not change the current system prompt.

After the history has been cleared, subsequent calls to **SendMessage** will not include any previous messages from the conversation history.

If you call this method while enumerating the messages in the conversation history using the **GetFirstMessage** and **GetNextMessage** methods, you must call **GetFirstMessage** again to begin a new enumeration. Calling the **GetNextMessage** method immediately after calling **ClearHistory** will result in an error.

Calling this method will not affect the current values of the **Prompt** or **Response** properties. Those properties return the most recent message prompt and model response for the client session.

See Also

[HistorySize Property](#), [MessageCount Property](#), [Prompt Property](#), [Response Property](#), [Reset Method](#), [TrimHistory Method](#)

Connect Method

The **Connect** method establishes a connection to the specified large language model service provider and creates a client session.

Syntax

`object.Connect( [Provider], [ModelName], [ApiKey], [BaseUrl], [Timeout], [Options] )`

Parameters

Provider

An optional parameter which identifies the service provider. If specified, this parameter must be one of the predefined **llmProvider** constants and cannot be zero. If the parameter is omitted, the control will use the value of the **Provider** property to establish the connection. For more information about providers, see the Remarks section below.

ModelName

An optional String that specifies the model name to use for the session. If the parameter is omitted, the value of the **ModelName** property will be used, if one is defined. If no model name is specified, the default model for the provider will be used. Providers without a default model require an explicit model name. This typically includes models accessed using the Microsoft Azure Foundry or locally hosted inference providers.

ApiKey

An optional String that specifies the API key used to authenticate with the provider. If the parameter is omitted, the value of the **ApiKey** property will be used. The API key may be provided using a literal string, an environment variable, or a value stored in the Windows Credential Manager. Using an environment variable or secure credential storage is recommended for production applications to avoid exposing sensitive information in source code or application binaries.

BaseUrl

An optional String that specifies the base URL for the provider endpoint. If this parameter is omitted, the value of the **BaseUrl** property will be used. If no base URL is specified, the method will use the default endpoint for the selected provider. Some providers, such as Microsoft Foundry or local inference services, will require you to provide a specific base URL endpoint.

Timeout

An optional Integer parameter which specifies the timeout period, in seconds, for connection and request operations. If this parameter is omitted, the value of the **Timeout** property will be used.

Options

An optional parameter which specifies one or more option flags that control how the connection is established. If this parameter is omitted, the value of the **Options** property will be used. This parameter can be zero or a combination of the following values:

Value	Description
llmOptionNone	A standard connection to the server is established using the default behavior for the selected provider. No additional options are enabled, and the connection will use the provider's default protocol, caching behavior and request headers.
llmOptionNoCache	Disables provider and model metadata caching for the client session. When this option is specified, the control will not reuse

	cached metadata, and provider or model information will be retrieved from the server each time it is required. This may be useful when testing or when current data is required.
<code>llmOptionKeepAlive</code>	Enables persistent HTTP connections using the keep-alive mechanism. When enabled, the underlying HTTP connection may be reused for multiple requests, reducing connection overhead and improving performance. If this option is not specified, the connection may be closed after each request.
<code>llmOptionProxy</code>	Specifies that the connection should be made using the current Windows proxy server configuration. If the user does not have a proxy server configuration, this option is ignored. This option is typically used in environments where direct internet access is restricted.
<code>llmOptionNoUserAgent</code>	Prevents the control from sending a User-Agent header with requests to the provider. By default, a User-Agent string is included to identify the client. This option may be used when a minimal or anonymous request is required.
<code>llmOptionSecure</code>	Forces the use of a secure HTTPS connection when communicating with the provider. If the specified base URL or provider default would normally use an insecure protocol, it will be upgraded to a secure connection. Connections to providers such as OpenAI, Google and Anthropic will always be secure.
<code>llmOptionDefault</code>	Specifies the default option set, which is equivalent to <code>llmOptionNone</code> . No additional flags are enabled and the connection uses standard behavior.

Return Value

A value of **True** is returned if the connection was successful. If the method fails, it will return **False** and the **LastError** property will contain the error code.

Remarks

The **Connect** method creates a client session that is used for all subsequent operations with the selected provider. The control maintains the connection settings, authentication information, selected model, and conversation history for the session. If you call this method without specifying any parameters, it will use the control's property values as defaults.

The **Provider** parameter specifies the service provider that will be used to establish a connection. Provider identifiers are predefined constants built into the control and uniquely identify a specific provider. Applications should use the predefined constants (such as **`llmProviderOpenAI`** or **`llmProviderMicrosoft`**) rather than hard-coding numeric values directly in source code.

Refer to the [providers](#) page for a list of supported service providers and their default models.

If the service provider requires authentication, the API key can be provided in several formats, allowing applications to provide credentials in a way that balances convenience and security:

- **Literal string**

The API key is provided directly as a string. This is the simplest approach and is convenient for testing or small internal tools, but it is not recommended for production applications. A literal key may be exposed in source code, configuration files, diagnostic logs or the compiled

application binary.

- **Environment variable**

The name of an environment variable enclosed in percent symbols, for example `"%OPENAI_API_KEY%"`. The value of the environment variable is used as the API key. This avoids embedding the key directly in the application and is useful for development, scripts and deployment environments. However, environment variables may still be visible to the current user, inherited by child processes or exposed through system configuration, so they should still be protected appropriately.

- **Windows credential**

A credential name enclosed in braces, for example `"{MyAppName/OpenAI}"`. The API key is retrieved from the Windows Credential Manager using the specified name. This is the recommended approach for most Windows applications because the secret is stored outside the application and managed by the operating system. The credential can be created manually using Credential Manager, or programmatically by the application using the Windows Credential Management API. Applications should choose a unique credential name and document it clearly if users or administrators are expected to configure the value themselves.

For production applications, it is recommended that you avoid using literal API key strings and instead use an environment variable or a value stored in the Windows Credential Manager. If you must provide the API key as a literal string, you should take additional steps to protect it, such as storing the key in an encrypted form and limiting access to authorized users or processes. Avoid embedding API keys directly in application source code, configuration files, installers or other content that could be exposed through version control systems, logs or public repositories.

This method will wait until the connection has been established or the timeout period has elapsed. The connection established by this method represents a logical session. Depending on the provider and options specified, the underlying HTTP connection may be reused across requests or recreated as needed. Properties such as **KeepAlive** and **IdleTime** can be used to control connection behavior.

If the control is already connected to another provider, this method will explicitly close that connection by calling the **Disconnect** method prior to establishing the new connection.

Applications which only need to send a single prompt and return a response may find the **Ask** method easier to use. That method automatically manages the connection and returns the generated response as a String value.

Example

```
Private Sub cmdConnect_Click()  
    LlmClient1.Provider = llmProviderOpenAI  
    LlmClient1.ModelName = "gpt-5.4-nano"  
    LlmClient1.ApiKey = "%OPENAI_API_KEY%" ' Use an environment variable  
    LlmClient1.Timeout = 60  
  
    ' Establish a connection to the selected provider  
    If LlmClient1.Connect() Then  
        MsgBox "Connected to provider successfully", vbInformation  
  
        ' Send a simple prompt to the model and update a TextBox  
        LlmClient1.Prompt = "What is the capital of Denmark?"  
  
        If LlmClient1.SendMessage() Then  
            txtResponse.Text = LlmClient1.Response  
        Else
```

```
        MsgBox LlmClient1.LastErrorString, vbExclamation
    End If
Else
    MsgBox LlmClient1.LastErrorString, vbExclamation
End If
End Sub

Private Sub Form_Unload(Cancel As Integer)
    ' Disconnect the current session when the application exits
    If LlmClient1.IsConnected Then
        LlmClient1.Disconnect
    End If
End Sub
```

See Also

[ApiKey Property](#), [BaseUrl Property](#), [ModelName Property](#), [Options Property](#), [Provider Property](#), [Timeout Property](#), [Ask Method](#), [Disconnect Method](#), [SendMessage Method](#), [OnConnect Event](#)

Disconnect Method

Terminate the connection with a server.

Syntax

object.Disconnect

Parameters

None.

Return Value

A value of **True** is returned if the method succeeds. If the method fails, it will return **False** and the **LastError** property will contain the error code.

Remarks

The **Disconnect** method closes the active connection and releases all memory and resources associated with the specified client session. This includes the conversation history, cached message and response data, provider information and any other state maintained by the control. To preserve information from the session, retrieve it before calling this method.

Avoid calling this method while a blocking request is in progress. If a request must be canceled, call the **Cancel** method first and wait for the blocking operation to return before disconnecting the client session. The **IsBlocked** property can tell you if the control is in the middle of processing a blocking operation, such as retrieving the response to a message prompt.

See Also

[IsBlocked Property](#), [IsConnected Property](#), [Connect Method](#), [OnDisconnect Event](#)

EstimateTokens Method

The **EstimateTokens** method estimates the number of tokens in a string.

Syntax

object.EstimateTokens(*MessageText*)

Parameters

MessageText

A String containing the text to be analyzed.

Return Value

If the method succeeds, the return value is the estimated number of tokens in the specified string. If there are no text characters, or the string only contains whitespace, the method will return zero. If the method fails, the return value is -1. To get extended error information, check the value of the **LastError** property.

Remarks

The **EstimateTokens** method provides an approximate count of the number of tokens that would be required to represent the specified text for the current provider. This can be useful when estimating prompt size and ensuring that requests remain within model limits. This method does not require a connection to a provider and can be used independently to estimate token usage before establishing a connection or sending a request.

The *MessageText* parameter must contain valid text and cannot contain arbitrary binary data or embedded null characters. If malformed Unicode is detected in the string, the method will fail and return -1, with the last error code set to **stErrorInvalidUnicode**. If the string consists only of whitespace characters, including non-breaking spaces, the method will return zero.

A token is a unit of text used internally by large language models. Tokens are not the same as characters or words. In general, a token may represent a single word, part of a word, or a short sequence of characters. For example, common words may be represented as a single token, while less common or longer words may be split into multiple tokens. Punctuation and whitespace may also be represented as separate tokens.

As a general rule of thumb, one token corresponds to approximately three to four characters of English text. This can vary significantly depending on the content, language, and tokenization rules used by the provider.

Most providers distinguish between input tokens (the text sent to the model) and output tokens (the text generated by the model in response). Usage and billing are typically based on the total number of tokens processed, including both the prompt and the generated response. Monitoring token usage can help applications control costs and ensure that requests remain within the limits imposed by the selected model.

The tokenization rules used by each provider can vary, and the exact number of tokens used in a request is determined by the provider at runtime. The value returned by this method is an estimate only and should not be relied on as an exact measurement. The value of the **Provider** property can affect how the method calculates the estimated number of tokens in the string.

To determine how many input and output tokens have been used in a session, use the **TotalTokens** property.

See Also

[Provider Property](#), [TotalTokens Property](#), [Ask Method](#) [SendMessage Method](#)

ExportHistory Method

The **ExportHistory** method exports the conversation history to a JSON-formatted file.

Syntax

```
object.ExportHistory( FileName, [MessageCount], [Exported] )
```

Parameters

FileName

A string which specifies the name of the file to be created or overwritten. The string may contain environment variables in the path by enclosing the variable name in percent symbols. This parameter is required and cannot be an empty string.

MessageCount

An optional Integer parameter which specifies the number of recent messages and responses which should be exported. If this parameter is omitted or the value is zero, all messages in the current conversation are exported.

Exported

An optional Integer parameter passed by reference which will receive the number of messages which were exported when the method returns. If this information is not required, this parameter may be omitted.

Return Value

A value of **True** is returned if the method succeeds. If the method fails, it will return **False** and the **LastError** property will contain the error code.

The **ExportHistory** method exports the current conversation history associated with the client session to a [JSON-formatted](#) file. The exported history includes both client messages and model responses stored in the current session history.

This method only exports conversation history currently stored in memory for the client session. It cannot be used if the conversation history has been disabled by setting the history size to zero.

If the **FileName** parameter specifies a directory or device name, the method will fail. It is permitted to use environment variables in the file name by surrounding the variable name with the percent symbol. If the file name contains any leading or trailing space characters, they will be removed. If the file already exists, the current process must have permission to overwrite the file. If the file has the read-only attribute set, the method will fail and the last error code will be set to **tErrorAccessDenied**.

If the **MessageCount** parameter is non-zero, the method exports only the most recent messages in the conversation history. Older messages are skipped. If the specified count exceeds the number of available messages, all available messages are exported. To export all messages in the conversation history, you can simply omit this parameter.

The exported file uses UTF-8 encoded JSON text and is intended to be human-readable. Applications should not depend on the exact formatting or internal structure of the file because future versions of the library may include additional metadata or fields. To help prevent data loss, the method writes the exported history to a temporary file and only replaces the destination file after the export operation has completed successfully. If the export fails, any existing file specified by the *lpszFileName* parameter is left unchanged.

The exported file is intended to provide a simple mechanism for persisting conversation state between application sessions. A previously exported history file can later be restored using the **ImportHistory**

method.

Important: The conversation history may contain sensitive or private information. Applications should take reasonable precautions to protect exported history files, such as limiting access permissions or encrypting the exported file. Applications which allow users to export conversation history should consider informing users that the exported file may contain private information.

Example

```
Dim strFileName As String
Dim nExported As Long

strFileName = "%USERPROFILE%\Documents\conversation.json"

' Export the complete conversation history to a JSON file
If LlmClient1.ExportHistory(strFileName, 0, &nExported)) Then
    MsgBox "Exported " + CStr(nExported) + " messages", vbInformation
Else
    MsgBox "Unable to export the conversation history" + vbCrLf + _
        LlmClient1.LastErrorString, vbExclamation
End If
```

[MessageCount Property](#), [ClearHistory Method](#), [ImportHistory Method](#), [TrimHistory Method](#)

FindMessage Method

Searches the conversation history for a message or response that matches the specified text.

Syntax

`object.FindMessage( Pattern, [StartMessageId], [Options] )`

Parameters

Pattern

A string which specifies the text that should be searched for. This may be a literal string or it may specify a simplified regular expression. The **Options** parameter can be used to specify if the search is case-sensitive. This parameter must be provided and it cannot be an empty string or contain only whitespace characters.

StartMessageId

An optional Integer parameter which specifies the message ID that the search should begin with. If this parameter is omitted or the value is zero, the search begins with the oldest message in the client history.

Options

An optional Integer value that specifies one or more search options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
IlmSearchDefault	Search the entire message history for matching text.
IlmSearchPrompt	Search the history of message prompts for matching text.
IlmSearchResponse	Search the history of responses for matching text.
IlmSearchCaseSensitive	The pattern match will be case-sensitive. If this option is not specified, matches are not case-sensitive.
IlmSearchLiteralMatch	Perform a literal string search instead of using a regular expression.

Return Value

If a matching message is found, the method returns the unique message identifier for the message. If no message prompts and/or responses match the search pattern, the method returns zero and the **LastError** property will contain the error code.

Remarks

The **FindMessage** method searches the message history for text that matches a specific pattern. The search can be limited to prompts, responses, or both, depending on the options specified by the **Options** parameter. The pattern you are matching against must be a null-terminated string and it cannot consist of only whitespace characters (spaces, tabs, carriage returns and linefeeds).

If the **StartMessageId** parameter is non-zero, the method will begin searching with the first message whose identifier is equal to or greater than the specified value. Message identifiers are unique within a client session and are assigned incrementally, so newer messages will always have higher identifier values than older messages.

If the **Pattern** parameter does not contain any regular expression constructs (such as ^, \$, [], or

quantifiers like `*` and `+`), the search is performed using a simple substring comparison. Regular expression matching is automatically enabled when the pattern contains recognized regular expression constructs, unless the **11mSearchLiteralMatch** option is specified.

If a regular expression pattern is specified, the method compiles the pattern and searches the message content for a match. The regular expression matching uses a simplified version which only supports anchors, wildcards, match classes (enclosed in brackets) and a limited number of escape sequences such as `\d` to match any digit or `\s` to match any space character. It does not support grouping or replacement.

Supported regular expression constructs include:

- The caret `^` and dollar symbol `$` for the beginning and end of the content.
- The period `.` to match any character.
- Character classes such as `[abc]` which would match any of the characters enclosed in brackets.
- Negated classes such as `[^abc]` which would match if none of those characters are found.
- Escaped matches such as `\d` for digits, `\w` for word characters and `\s` for whitespace characters
- The `+` quantifier can be used to match one or more occurrences.
- The `*` quantifier will match zero or more occurrences.

This method uses a minimal regular expression parser and does not include support for complex constructs such as grouping, backreferences or alternation using the pipe `|` character. If you want to search for text which may contain characters typically used in regular expressions such as `[` or `$`, you can either escape them using a backslash, or you can use the **11mSearchLiteralMatch** option which forces the method to only perform a substring search.

Applications searching for arbitrary user-entered text should usually specify the **11mSearchLiteralMatch** option to avoid unintended interpretation of regular expression characters. This will avoid situations where a user may unexpectedly enter search text which appears to be a regular expression pattern.

Regular expression matches are performed against the entire prompt or response text and are not implicitly anchored. It is also important to keep in mind that matches can span multiple lines (they do not end at line breaks) and will attempt to match as much text as possible (this is sometimes referred to as a "greedy match"). This can yield unexpected results if you use wildcards in the pattern which are overly broad, matching large sections of the prompt or response text. For example, a pattern like `".*abc"` will match everything until the last instance of "abc" is found.

If neither the **11mSearchPrompt** nor **11mSearchResponse** options are explicitly specified, the search will match against both message prompts and responses.

The **GetMessage** method can be used to obtain the contents of the prompt and/or response for a matching message.

See Also

[HistorySize Property](#), [MessageCount Property](#), [GetFirstMessage Method](#), [GetMessage Method](#), [GetNextMessage Method](#)

GetFirstMessage Method

The **GetFirstMessage** method returns the first available message in the conversation history.

Syntax

```
object.GetFirstMessage( [Prompt], [Response], [Timestamp], [MessageId] )
```

Parameters

Prompt

An optional String passed by reference. When the method returns, this parameter will contain the message prompt for the oldest message in the conversation history. If this parameter is omitted, the method will not return the message prompt text. You cannot omit both this parameter and the **Response** parameter.

Response

An optional String passed by reference. When the method returns, this parameter will contain the response for the oldest message in the conversation history. If this parameter is omitted, the method will not return the response text. You cannot omit both this parameter and the **Prompt** parameter.

Timestamp

An optional String or Date parameter passed by reference. When the method returns, this parameter will contain the local date and time the response was returned by the server. If this parameter is a String, the timestamp is returned as a local date and time formatted for the current user's locale. If the parameter is a Date, the value is returned as a local date and time. If no timestamp is available, a String parameter receives an empty string and a Date parameter receives a value of zero. If this information is not required, this parameter can be omitted.

MessageId

An optional Integer parameter passed by reference. When the method returns, this parameter will contain the message ID for the message. If this information is not required, this parameter may be omitted.

Return Value

A value of **True** is returned if the method succeeds. If there are no messages in the client history, or an error occurs, the method returns **False** and the **LastError** property will contain the error code.

Remarks

The **GetFirstMessage** method retrieves the first message prompt and associated response from the client conversation history. This method is typically used in conjunction with the **GetNextMessage** method to enumerate all messages in the current session.

Messages are returned in chronological order, beginning with the oldest message in the client history. New messages are always appended to the end of the history, and if the history is trimmed, older messages are removed first. The order of messages reflects the sequence in which they were submitted.

See the **Response** property for additional information about text formatting and Unicode handling for model responses.

To determine the number of messages in the conversation history, use the **MessageCount** property.

Example

```
Dim strPrompt As String
Dim strResponse As String
Dim strTimestamp As String
Dim nMessageId As Long

If LlmClient1.GetFirstMessage(strPrompt, strResponse, strTimestamp, nMessageId)
Then
    Do
        Debug.Print "Message ID: " & CStr(nMessageId)
        Debug.Print "Prompt: " & strPrompt
        Debug.Print "Response: " & strResponse
        Debug.Print "Timestamp: " & strTimestamp
        Debug.Print String(60, "-")

        Loop While LlmClient1.GetNextMessage( _
            strPrompt, _
            strResponse, _
            strTimestamp, _
            nMessageId)
    Else
        MsgBox "No messages are available in the conversation history.", _
            vbInformation
    End If
```

GetFirstModel Method

The **GetFirstModel** method retrieves information about the first available model for the current service provider.

Syntax

object.GetFirstModel(*ModelName*, [*MaxTokens*], [*ContextSize*], [*Flags*])

Parameters

ModelName

A String passed by reference which will contain the name of the first model when the method returns. This parameter cannot be omitted.

MaxTokens

An optional Integer passed by reference. When the method returns, this parameter will contain the maximum number of output tokens that can be generated by the model for a single response.

ContextSize

An optional Integer passed by reference. When the method returns, this parameter will contain the context size supported by the model. This is the maximum number of tokens the model can process in a single request.

Flags

An optional Integer passed by reference. When the method returns, this parameter will specify one or more bitflags that describe the capabilities of the model. If an error occurs, this value will be zero. If this information is not required, the parameter may be omitted.

Constant	Value	Description
IlmModelFlagNone	&H0000	No model capabilities defined
IlmModelFlagChat	&H0001	Supports conversational text generation
IlmModelFlagSystemRole	&H0002	Accepts a system role message in the input
IlmModelFlagStreaming	&H0004	Supports streaming responses
IlmModelFlagStructured	&H0008	Supports structured output (e.g., JSON or schema)
IlmModelFlagVision	&H0010	Supports image inputs (multimodal)
IlmModelFlagTools	&H0020	Supports tool or function calling
IlmModelFlagReasoning	&H0040	Supports reasoning-oriented generation
IlmModelFlagResponses	&H0080	Supports the Responses API (unified endpoint)
IlmModelFlagFunctions	&H0100	Supports OpenAI-style function calling with schemas
IlmModelFlagAudio	&H0200	Supports audio output (text-to-speech)
IlmModelFlagImage	&H0400	Supports image generation
IlmModelFlagVideo	&H0800	Supports video generation

llmModelFlagTranscription	&H1000	Supports speech-to-text transcription
llmModelFlagInstructions	&H2000	Supports a dedicated instruction field outside message lists
llmModelFlagMaxCompletionTokens	&H4000	Uses max_completion_tokens instead of max_tokens in requests
llmModelFlagInferred	&H80000	Capabilities are inferred rather than explicitly defined

Return Value

A value of **True** is returned if the method succeeds. If the method fails, it will return **False** and the **LastError** property will contain the error code.

Remarks

The **GetFirstModel** method begins enumeration of the models available for the provider associated with the client session. The client must be connected to a provider before calling this method. The values are based on metadata and information returned by the provider in response to a request for a list of supported inference models.

The model list may be cached for a limited period of time to avoid unnecessary requests to the provider. Use **CacheTime** property to determine or change the cache lifetime for the client session.

The model capabilities reported by this method are intended to help an application select an appropriate model. Providers may change their model availability, capabilities, or status over time.

The presence of a model in the provider's model list does not guarantee that it can be used by the current client. Access to specific models may depend on the provider account, subscription level, region, deployment configuration, or other provider-specific requirements. Applications should use **ValidateModel** before selecting a model, particularly if the model name was chosen by the user or restored from a saved configuration.

The **MaxTokens** value returned by this method represents the maximum output token limit reported for the model. This limit only applies to generated content and may be lower than the model's total context window. The client can further restrict the length of generated responses by setting the **MaxTokens** property to a smaller value. Setting the property does not increase the model's limit; it only places an additional limit on responses generated by the model.

The **ContextSize** value represents the maximum number of tokens the model can process in a single request, including the system prompt, conversation history, user messages, and generated output. Most cloud-based service providers offer models which support very large context sizes, while limiting the maximum number of tokens that can be generated in a single response. For example, a model may support a context window of 1,000,000 tokens, allowing it to process very large conversations or documents, while limiting individual responses to 128,000 output tokens.

Token counts do not directly correspond to characters or words, but as a general approximation, one token represents about 3-4 English characters. The exact number of tokens depends on the language, formatting, and content being processed. A context window of 1,000,000 tokens could hold several thousand pages of text or source code.

Example

```
Dim strModel As String
Dim nMaxTokens As Long
Dim nContextSize As Long
```

```
Dim nFlags As Long
```

```
If LlmClient1.GetFirstModel(strModel, nMaxTokens, nContextSize, nFlags) Then
    Do
        Debug.Print "Model: " & strModel
        Debug.Print "Max Tokens: " & CStr(nMaxTokens)
        Debug.Print "Context Size: " & CStr(nContextSize)

        If (nFlags And llmModelFlagReasoning) <> 0 Then
            Debug.Print "Supports reasoning"
        End If

        Debug.Print ""

        Loop While LlmClient1.GetNextModel(strModel, nMaxTokens, nContextSize, nFlags)
    Else
        MsgBox "Unable to retrieve model list. Error " & _
            CStr(LlmClient1.LastError), vbExclamation
    End If
```

[GetNextModel Method](#), [ValidateModel Method](#)

GetHeader Method

Returns the value of an HTTP header from the server response.

Syntax

object.GetHeader(*HeaderName*, *HeaderValue*)

Parameters

HeaderName

A String value which specifies the name of the HTTP response header. The header names are not case-sensitive. Header names may only contain ASCII letters, numbers and a restricted subset of punctuation characters. Header names cannot contain Unicode or ANSI multi-byte character sequences.

HeaderValue

A String passed by reference which will contain the value of the header when the method returns. This parameter is required.

Return Value

A value of **True** is returned if the method completed successfully. If the method fails, it will return **False** and the **LastError** property will contain the error code.

Remarks

The **GetHeader** method returns the value of a response header from the last request made to the service provider.

This method is intended for applications that need lower-level access to provider-specific response headers. Most applications do not need to call this method. Standard response information, such as the HTTP status code, response text, token usage, model name, and elapsed time, is available through the control's properties.

The headers returned by a service provider can vary depending on the provider, model, endpoint, account configuration, and the specific request being made. Applications should not assume that a particular header will always be present unless it is documented by the service provider.

If no response headers are available, or if the specified header was not returned by the server, the *HeaderValue* parameter will contain an empty string when the method returns.

See Also

[HttpStatus Property](#), [Options Property](#), [UserAgent Property](#), [ClearHeaders Method](#), [SendMessage Method](#), [SetHeader Method](#)

GetMessage Method

The **GetMessage** method retrieves a specific message prompt and response from the client history using a message identifier.

Syntax

```
object.GetMessage( MessageId, [Prompt], [Response], [Timestamp] )
```

Parameters

MessageId

An Integer value which identifies a specific message and response. This value must be greater than zero.

Prompt

An optional String passed by reference. When the method returns, this parameter will contain the message prompt for the specified message in the conversation history. If this parameter is omitted, the method will not return the message prompt text. You cannot omit both this parameter and the *Response* parameter.

Response

An optional String passed by reference. When the method returns, this parameter will contain the response for the specified message in the conversation history. If this parameter is omitted, the method will not return the response text. You cannot omit both this parameter and the *Prompt* parameter.

Timestamp

An optional String or Date parameter passed by reference. When the method returns, this parameter will contain the local date and time the response was returned by the server. If this parameter is a String, the timestamp is returned as a local date and time formatted for the current user's locale. If the parameter is a Date, the value is returned as a local date and time. If no timestamp is available, a String parameter receives an empty string and a Date parameter receives a value of zero. If this information is not required, this parameter can be omitted.

Return Value

A value of **True** is returned if the method succeeds. If the method fails, it will return **False** and the **LastError** property will contain the error code.

Remarks

The **GetMessage** method retrieves a specific message prompt and its associated response from the client session history. This method can be used when an application has stored a message identifier or has obtained one using methods such as **FindMessage**. Message identifiers are returned when sending requests using the **SendMessage** method.

If message history has been disabled, the control does not retain previous messages. However, the most recent prompt and response are still available and may be retrieved specifying its message identifier. Applications that need to preserve this information should make a copy of the data before issuing another request.

Message identifiers are unique only within the client session that created them. They are not guaranteed to be unique across different client sessions, processes, or future executions of the application. Applications should treat message identifiers as opaque values and should not make assumptions about how they are assigned internally. It is guaranteed, however, that newer messages

will always be assigned larger message identifier values than older messages within the same session.

If the specified message identifier does not match a message currently stored in the client history, the method fails. This can occur if the message has been removed because the history was cleared or trimmed.

See the **Response** property for additional information about text formatting and Unicode handling for model responses.

See Also

[Prompt Property](#), [Response Property](#), [FindMessage Method](#), [GetFirstMessage Method](#), [GetNextMessage Method](#), [SendMessage Method](#)

GetNextMessage Method

The **GetNextMessage** method returns the next available message in the conversation history.

Syntax

```
object.GetNextMessage( [Prompt], [Response], [Timestamp], [MessageId] )
```

Parameters

Prompt

An optional String passed by reference. When the method returns, this parameter will contain the message prompt for the next message in the conversation history. If this parameter is omitted, the method will not return the message prompt text. You cannot omit both this parameter and the **Response** parameter.

Response

An optional String passed by reference. When the method returns, this parameter will contain the response for the next message in the conversation history. If this parameter is omitted, the method will not return the response text. You cannot omit both this parameter and the **Prompt** parameter.

Timestamp

An optional String or Date parameter passed by reference. When the method returns, this parameter will contain the local date and time the response was returned by the server. If this parameter is a String, the timestamp is returned as a local date and time formatted for the current user's locale. If the parameter is a Date, the value is returned as a local date and time. If no timestamp is available, a String parameter receives an empty string and a Date parameter receives a value of zero. If this information is not required, this parameter can be omitted.

MessageId

An optional Integer parameter passed by reference. When the method returns, this parameter will contain the message ID for the message. If this information is not required, this parameter may be omitted.

Return Value

A value of **True** is returned if the method succeeds. If there are no messages in the client history, or an error occurs, the method returns **False** and the **LastError** property will contain the error code.

Remarks

The **GetNextMessage** method retrieves the next message prompt and associated response from the client conversation history.

The application must call **GetFirstMessage** before calling this method. Messages are returned in chronological order, beginning with the oldest message in the client history. New messages are always appended to the end of the history, and if the history is trimmed, older messages are removed first. The order of messages is stable and reflects the sequence in which they were submitted.

See the **Response** property for additional information about text formatting and Unicode handling for model responses.

To determine the number of messages in the conversation history, use the **MessageCount** property.

Example

```
Dim strPrompt As String
```

```

Dim strResponse As String
Dim strTimestamp As String
Dim nMessageId As Long

If LlmClient1.GetFirstMessage(strPrompt, strResponse, strTimestamp, nMessageId)
Then
    Do
        Debug.Print "Message ID: " & CStr(nMessageId)
        Debug.Print "Prompt: " & strPrompt
        Debug.Print "Response: " & strResponse
        Debug.Print "Timestamp: " & strTimestamp
        Debug.Print String(60, "-")

        Loop While LlmClient1.GetNextMessage( _
            strPrompt, _
            strResponse, _
            strTimestamp, _
            nMessageId)
    Else
        MsgBox "No messages are available in the conversation history.", _
            vbInformation
    End If

```

See Also

[HistorySize Property](#), [MessageCount Property](#), [Response Property](#), [GetFirstMessage Method](#), [GetMessage Method](#)

GetNextModel Method

The **GetNextModel** method retrieves information about the next available model for the current service provider.

Syntax

object.GetNextModel(*ModelName*, [*MaxTokens*], [*ContextSize*], [*Flags*])

Parameters

ModelName

A String passed by reference which will contain the name of the first model when the method returns. This parameter cannot be omitted.

MaxTokens

An optional Integer passed by reference. When the method returns, this parameter will contain the maximum number of output tokens that can be generated by the model for a single response.

ContextSize

An optional Integer passed by reference. When the method returns, this parameter will contain the context size supported by the model. This is the maximum number of tokens the model can process in a single request.

Flags

An optional Integer passed by reference. When the method returns, this parameter will specify one or more bitflags that describe the capabilities of the model. If an error occurs, this value will be zero. If this information is not required, the parameter may be omitted.

Constant	Value	Description
IlmModelFlagNone	&H0000	No model capabilities defined
IlmModelFlagChat	&H0001	Supports conversational text generation
IlmModelFlagSystemRole	&H0002	Accepts a system role message in the input
IlmModelFlagStreaming	&H0004	Supports streaming responses
IlmModelFlagStructured	&H0008	Supports structured output (e.g., JSON or schema)
IlmModelFlagVision	&H0010	Supports image inputs (multimodal)
IlmModelFlagTools	&H0020	Supports tool or function calling
IlmModelFlagReasoning	&H0040	Supports reasoning-oriented generation
IlmModelFlagResponses	&H0080	Supports the Responses API (unified endpoint)
IlmModelFlagFunctions	&H0100	Supports OpenAI-style function calling with schemas
IlmModelFlagAudio	&H0200	Supports audio output (text-to-speech)
IlmModelFlagImage	&H0400	Supports image generation
IlmModelFlagVideo	&H0800	Supports video generation

llmModelFlagTranscription	&H1000	Supports speech-to-text transcription
llmModelFlagInstructions	&H2000	Supports a dedicated instruction field outside message lists
llmModelFlagMaxCompletionTokens	&H4000	Uses max_completion_tokens instead of max_tokens in requests
llmModelFlagInferred	&H80000	Capabilities are inferred rather than explicitly defined

Return Value

A value of **True** is returned if the method succeeds. If the method fails, it will return **False** and the **LastError** property will contain the error code.

Remarks

The **GetNextModel** method continues enumeration of the models available for the provider associated with the client session. The **GetFirstModel** method must be called to begin the enumeration prior to calling this method. The values are based on metadata and information returned by the provider in response to a request for a list of supported inference models.

The model list may be cached for a limited period of time to avoid unnecessary requests to the provider. Use **CacheTime** property to determine or change the cache lifetime for the client session.

The model capabilities reported by this method are intended to help an application select an appropriate model. Providers may change their model availability, capabilities, or status over time.

The presence of a model in the provider's model list does not guarantee that it can be used by the current client. Access to specific models may depend on the provider account, subscription level, region, deployment configuration, or other provider-specific requirements. Applications should use **ValidateModel** before selecting a model, particularly if the model name was chosen by the user or restored from a saved configuration.

The **MaxTokens** value returned by this method represents the maximum output token limit reported for the model. This limit only applies to generated content and may be lower than the model's total context window. The client can further restrict the length of generated responses by setting the **MaxTokens** property to a smaller value. Setting the property does not increase the model's limit; it only places an additional limit on responses generated by the model.

The **ContextSize** value represents the maximum number of tokens the model can process in a single request, including the system prompt, conversation history, user messages, and generated output. Most cloud-based service providers offer models which support very large context sizes, while limiting the maximum number of tokens that can be generated in a single response.

Example

```
Dim strModel As String
Dim nMaxTokens As Long
Dim nContextSize As Long
Dim nFlags As Long

If LlmClient1.GetFirstModel(strModel, nMaxTokens, nContextSize, nFlags) Then
    Do
        Debug.Print "Model: " & strModel
        Debug.Print "Max Tokens: " & CStr(nMaxTokens)
        Debug.Print "Context Size: " & CStr(nContextSize)
```

```
    If (nFlags And llmModelFlagReasoning) <> 0 Then
        Debug.Print "Supports reasoning"
    End If

    Debug.Print ""

    Loop While LlmClient1.GetNextModel(strModel, nMaxTokens, nContextSize, nFlags)
Else
    MsgBox "Unable to retrieve model list. Error " & _
        CStr(LlmClient1.LastError), vbExclamation
End If
```

GetProvider Method

The **GetProvider** method returns information about the specified service provider.

Syntax

```
object.GetProvider( Provider, [Name], [BaseUrl], [DefaultModel], [Flags], )
```

Parameters

Provider
Specifies the service provider. This parameter must be one of the **llmProvider** constants and cannot be zero. If the provider identifier is invalid, the method will fail. For more information about providers, see the Remarks section below.

Name
An optional String parameter passed by reference. When the method returns, this will contain a canonical version of the provider's name, such as **"OpenAI"**. This String value may be used for identification or display in the user interface. If this information is not required, the parameter may be omitted.

BaseUrl
An optional String parameter passed by reference. When the method returns, this will contain the default base URL endpoint used to issue requests to the service provider. If the provider does not have a default endpoint, this string will be empty and the application will be required to provide a base URL when establishing a connection. If this information is not required, the parameter may be omitted.

DefaultModel
An optional String parameter passed by reference. When the method returns, this will contain the name of the default model used for inference. Not all providers have a default model, and in this case an empty string will be returned. If a provider does not have a default model, a model name must be provided when establishing a connection. If this information is not required, the parameter may be omitted.

Flags
An optional Integer passed by reference. When the method returns, this parameter will specify one or more bitflags that describe the requirements and capabilities of the provider. If this information is not required, the parameter may be omitted.

Constant	Value	Description
llmProviderFlagNone	0	No provider requirements specified
llmProviderFlagRequireTls	&H0001	Requires a secure TLS (HTTPS) connection
llmProviderFlagRequireAuth	&H0002	Requires authentication (e.g., API key or token)
llmProviderFlagApiVersion	&H0004	Requires an explicit API version parameter
llmProviderFlagLocal	&H0008	Locally hosted provider (LM Studio, Ollama, etc.)
llmProviderFlagModelList	&H0010	Supports enumerating available models
llmProviderFlagModelInfo	&H0020	Supports retrieving detailed model information

Return Value

A value of **True** is returned if the method succeeds. If the **Provider** parameter is invalid, the method will return **False** and the **LastError** property will contain the error code.

Remarks

The **GetProvider** method returns general information about a provider, including its name, default base URL endpoint, default model, and related configuration values.

The **ProviderId** parameter specifies the numeric identifier assigned to a supported provider. Provider identifiers are predefined constants built into the control and are assigned fixed values beginning at 1 and increasing sequentially for each provider. These identifiers are stable and are intended to uniquely identify a provider regardless of its display name. Applications should use the predefined constants (such as **llmProviderOpenAI** or **llmProviderMicrosoft**) rather than hard-coding numeric values directly in source code.

Refer to the [providers](#) page for a list of supported service providers and their default models.

This method does not require an active client session and can be used to query provider information before connecting to a provider. The information returned by this method describes the provider defaults defined by the control. A client session may use different values if the application overrides the base URL, model name or settings.

Example

```
Private Sub Form_Load()  
    Dim nProviderId As Long  
    Dim strProvider As String  
  
    ComboProviders.Clear  
  
    ' Enumerate through all the supported providers. The local  
    ' provider is always the first available service provider.  
    nProviderId = llmProviderLocal  
  
    Do While LlmClient1.GetProvider(nProviderId, strProvider)  
        ComboProviders.AddItem strProvider  
  
        ' Store the provider ID with the item  
        ComboProviders.ItemData(ComboProviders.NewIndex) = nProviderId  
  
        nProviderId = nProviderId + 1  
    Loop  
  
    ' Select the first provider by default  
    If ComboProviders.ListCount > 0 Then  
        ComboProviders.ListIndex = 0  
    End If  
End Sub
```

ImportHistory Method

Imports a conversation history from a JSON-formatted file.

Syntax

object.ImportHistory(FileName, [MessageCount], [Imported])

Parameters

lpzFileName

A String which specifies the name of the import file.

nMessageCount

The number of the most recent messages and responses which should be imported. If this value is zero, all messages in the file are imported.

lpnImported

An Integer passed by reference which will receive the number of messages which were imported when the method returns. If this information is not required, this parameter may be omitted.

Return Value

A value of **True** is returned if the method succeeds. If the method fails, it will return **False** and the **LastError** property will contain the error code.

Remarks

The **ImportHistory** method imports a previously exported conversation history file and restores it as the active conversation history for the client session. Imported messages and responses become part of the current session history and are treated the same as messages generated during the current session.

Importing conversation history replaces the existing history associated with the client session. This method does not merge imported messages with the current conversation history or append them to the existing session. It is not necessary for your application to call **ClearHistory** prior to calling this function.

If the *FileName* parameter specifies a directory or device name, the method will fail. It is permitted to use environment variables in the file name by surrounding the variable name with the percent symbol. If the file name contains any leading or trailing space characters, they will be removed. The file must exist and the current process must have permission to read the file.

If the *MessageCount* parameter is non-zero, only the most recent messages and responses in the import file are restored. If the specified count exceeds the number of available messages in the file, all available messages are imported. If the total number of messages to be imported exceeds the current history size, the function will only import the most recent messages up to that limit. For example, if the import file contains 20 messages and the value of the **HistorySize** property is 15, the most recent 15 messages will be imported.

The import file must contain valid UTF-8 encoded JSON data in a format compatible with the **ExportHistory** method. If the file does not appear to contain a valid conversation history, the import operation fails before the current session history is cleared.

After the JSON data has been successfully parsed, the current session history is cleared before the imported messages and responses are added to the client session. If an error occurs while processing imported messages or responses, the previous conversation history cannot be restored and partial

import data may remain in the current session.

If the import file contains malformed message or response data, the **LastError** property will return **stErrorInvalidMessageFormat**.

Because imported history files may contain sensitive or private information, applications should take reasonable precautions to protect them. Applications which allow users to import conversation history should consider warning users before importing untrusted or unknown files.

Initialize Method

Initialize the control and validate the runtime license key.

Syntax

```
object.Initialize( [LicenseKey] )
```

Parameters

LicenseKey

An optional String value which specifies a runtime license key used to initialize the control. If the license key is omitted or passed as an empty string, a development license must be installed on the local system.

Return Value

A value of **True** is returned if the method succeeds. If the method fails, it will return **False** and the **LastError** property will contain the error code.

Remarks

This method dynamically loads other system libraries and allocates thread local storage. In most cases, it is not necessary to call this method directly because it is automatically invoked when an instance of the control is created by the container. However, if the control is created dynamically using **CreateObject** or a similar method, this must be the first method that is called before you attempt to modify any property values or invoke other methods. Failure to initialize the control may result in subsequent errors and/or cause an exception to be raised.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the control will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the control was created.

If the control is being used within another DLL, it is important that you do not attempt to create an instance of the control or call the **Initialize** method from within the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is written in C++ and it is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for any static and global C++ objects and has the same restrictions.

Example

```
Set objClient = CreateObject("SocketTools.LlmClient.12")

If Not objClient.Initialize(strLicenseKey)
    MsgBox "Unable to initialize the SocketTools LlmClient control"
End
End If
```

NormalizeText Method

Normalizes message text by removing extraneous whitespace and applying consistent formatting.

Syntax

object.NormalizeText(*Prompt*)

Parameters

Prompt

A String which contains the text which should be normalized.

Return Value

A **String** value which contains the normalized text. If the *Prompt* parameter contains only space and line break characters, an empty string will be returned.

Remarks

The **NormalizeText** method processes the input string, Although removing unnecessary whitespace may slightly reduce token usage, the primary benefit is producing cleaner and more consistent input for the model to process.

Line break characters are normalized to use Windows end-of-line conventions. Isolated carriage return or line feed characters, Unicode line and paragraph separators, and form feed characters are converted to CRLF sequences. Multiple consecutive line breaks are reduced to improve consistency.

Normalization can be useful when comparing prompts, checking for empty or whitespace-only input, or applying simple validation rules before a request is submitted. It does not attempt to determine whether the text is safe, appropriate, or semantically valid. Applications should perform any additional validation required for their own use case.

Using this method is optional. Prompt text does not need to be normalized before it is sent to a provider, and using this method is not a required sanitization step. If preserving the exact formatting of the original text is important, such as indentation, tables, or code samples, the application should send the original text instead.

See Also

[Prompt Property](#), [Response Property](#), [EstimateTokens](#), [SendMessage](#)

Reset Method

Reset the internal state of the control.

Syntax

object.Reset

Parameters

None.

Return Value

None.

Remarks

The **Reset** method resets the control to its initial state. Any active connection to the service provider is closed, the conversation history is cleared, and token usage statistics for the session are reset. Property values are set back to their internal defaults. This includes clearing the current provider ID, model name, and any authentication tokens.

If a blocking operation is currently in progress, this method will fail. Applications should check the value of the **IsBlocked** property to determine if the client is busy before attempting to reset the session.

See Also

[IsBlocked Property](#), [IsConnected Property](#), [Cancel Method](#), [Initialize Method](#), [Uninitialize Method](#)

SendMessage Method

The **SendMessage** method sends a prompt to the current model and returns the generated response.

Syntax

object.SendMessage([*Prompt*], [*Response*], [*MessageId*])

Parameters

Prompt

An optional String which specifies the message prompt which should be sent to the model. If the **Prompt** parameter is not specified, the method will use the current value of the **Prompt** property. A prompt cannot consist only of spaces and line break characters. If the prompt does not contain any text, the method will fail.

Response

An optional String passed by reference which will contain the model's response to the prompt when the method returns. If the **Response** parameter is not specified, the application can obtain the current response by getting the value of the **Response** property. If this parameter is specified and the method fails, an empty string will be returned.

MessageId

An optional Integer passed by reference which will contain the message ID assigned to the message. If this information is not required, this parameter can be omitted.

Return Value

A value of **True** is returned if the method succeeds. If the method fails, it will return **False** and the **LastError** property will contain the error code.

Remarks

The **SendMessage** method sends a text prompt to the model and processes the response. This method performs a blocking operation. It will not return until the request has completed, an error has occurred, or the operation has timed out. It is recommended that the user interface provide visual feedback to the user while waiting for the response.

An application which accepts prompts provided by a user should apply appropriate validation, filtering, or normalization before sending requests to the service provider. The **ValidateText** method verifies that the prompt contains valid message text and the **NormalizeText** method can be used to normalize text formatting.

The validation and normalization methods do not perform any semantic analysis of the prompt and do not provide protection against malicious or intentionally misleading input. It is the responsibility of the application to ensure that user-provided input is appropriate for its intended use. This includes considering scenarios where input may attempt to override instructions, inject unintended prompts, or otherwise influence the behavior of the model.

Line breaks in the response text are normalized before being stored in the client history. Line feed and carriage return characters are converted to the standard Windows CRLF end-of-line sequence, ensuring consistent formatting across different providers and applications. This also helps ensure compatibility with Windows common controls and other user interface components.

Some models are capable of performing additional internal reasoning before generating a response.

The amount of reasoning performed and whether it is exposed by the provider is model-specific. The control returns the final response intended for the user and does not currently expose model reasoning or intermediate processing steps. This behavior ensures consistent results across providers, regardless of how individual models implement or expose reasoning capabilities.

If the ***MessageId*** parameter is specified, it will receive a unique identifier for the message within the current client session. Message identifiers are assigned sequentially, but applications should treat them as opaque values. They are only guaranteed to be unique within a single session and should not be compared across different client sessions. You can retrieve a specific message from the conversation history using the **GetMessage** method.

This method automatically adds the message to the conversation history for the session. Subsequent calls will include previous messages as context, subject to any configured history or token limits. To clear the conversation context, call the **ClearHistory** method.

The value of the **Prompt** and **Response** properties will be updated when this method returns. See the **Response** property for additional information about text formatting and Unicode handling for model responses.

For simple request and response operations, applications can use the **Ask** method instead of explicitly calling the **Connect**, **SendMessage** and **Disconnect** methods.

Example

```
LlmClient1.ProviderName = "Local"
LlmClient1.BaseUrl = "http://127.0.0.1:1234/v1/"
LlmClient1.ModelName = "mistralai/mistral-7b-instruct-v0.3"

' Connect to a locally hosted model using LM Studio
If LlmClient1.Connect() Then
    Dim strPrompt As String
    Dim strResponse As String
    Dim nMessageId As Long

    strPrompt = "How do you calculate the volume of a sphere?"

    ' Send the prompt to the model and display the response
    If LlmClient1.SendMessage(strPrompt, strResponse, nMessageId) Then
        MsgBox strResponse, vbInformation, "Message " & nMessageId
    Else
        MsgBox LlmClient1.LastErrorString, vbExclamation, "Error"
    End If

    LlmClient1.Disconnect
Else
    ' Unable to connect to the local server
    MsgBox LlmClient1.LastErrorString, vbExclamation, "Error"
End If
```

SetHeader Method

Sets the value of a custom HTTP header used with subsequent requests.

Syntax

object.SetHeader(HeaderName, HeaderValue)

Parameters

HeaderName

A String value which specifies the name of the HTTP request header. The header names are not case-sensitive.

HeaderValue

A String value which specifies the header value. Header values cannot contain carriage-return or linefeed characters. If the value contains Unicode characters, they will be UTF-8 encoded. If this parameter is an empty string, the header field is deleted from the request headers.

Return Value

A value of **True** is returned if the method completed successfully. If the method fails, it will return **False** and the **LastError** property will contain the error code.

Remarks

The **SetHeader** method assigns a custom HTTP request header that will be included with subsequent requests made using the current client session. If the specified header already exists in the custom header list, its value will be replaced. If the header value is an empty string, the header will be removed.

This method is intended for advanced applications that require lower-level access to provider-specific functionality. Most applications should not need to use custom request headers. Some headers are managed internally by the control and cannot be overridden using this method. This includes headers required for authentication, content formatting, message length, host identification, and other protocol-specific functionality required by the current provider.

Examples of headers that are managed internally by the control include:

- **Authorization**
- **Content-Length**
- **Content-Type**
- **Host**
- **User-Agent**

Custom headers remain associated with the current client session until they are removed using the **ClearHeaders** method or the control is reset or uninitialized.

TrimHistory Method

The **TrimHistory** method removes older messages from the conversation history.

Syntax

object.TrimHistory(*MessageCount*, [*MaxTokens*])

Parameters

MessageCount

The number of messages to remove from the beginning of the conversation history. If this value is zero, messages are only removed if required by the **MaxTokens** parameter. If this value is equal to or greater than the number of messages in the history, the entire history is cleared.

MaxTokens

An optional Integer parameter which specifies the maximum number of input tokens that should remain in the conversation history. If this parameter is omitted or the value is zero, token usage is not checked. If the current history exceeds this value, additional older messages may be deleted until the total input token count is below the specified limit.

Return Value

An Integer value which specifies the number of messages that were removed from the history. A value of -1 indicates an error has occurred and the **LastError** property will contain the error code. If there are no messages in the conversation history, or the history has been disabled, the method will return zero.

Remarks

The **TrimHistory** method removes messages from the beginning of the conversation history. This can be used to reduce memory usage, discard older context, or limit how much previous conversation text is included with future requests.

The **MessageCount** parameter specifies the minimum number of older messages to remove. If **MaxTokens** is greater than zero, the method also checks the total number of input tokens currently stored in the message history. If the token count exceeds the specified limit, additional older messages will be removed until the total input token count is below the specified threshold.

When both parameters are specified, the method may remove more messages than requested by **MessageCount** to reduce the token count below the limit specified by **MaxTokens**. The return value always indicates the actual number of messages removed.

If the number of messages to remove is equal to or greater than the number of messages currently stored, the entire conversation history is cleared. This is equivalent to calling the **ClearHistory** method. If you remove any messages from the history method while enumerating the messages using the **GetFirstMessage** and **GetNextMessage** methods, you must call **GetFirstMessage** again to begin a new enumeration.

This method only removes the local message and response history maintained by the client session. It does not change the current provider, model, system prompt, connection settings or cached provider metadata.

See Also

[HistorySize Property](#), [MessageCount Property](#), [ClearHistory Method](#), [GetFirstMessage Method](#), [GetNextMessage Method](#)

Uninitialize Method

Uninitialize the control and release any system resources that were allocated.

Syntax

object.Uninitialize

Parameters

None.

Return Value

None.

Remarks

The **Uninitialize** method terminates any connection established by the control and resets the internal state of the control. This method is not typically used because any resources that have been allocated by an instance of the control will automatically be released when it is destroyed.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the control will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the control was created. An application should only call the **Uninitialize** method if it has explicitly called the **Initialize** method.

[Initialize Method](#)

ValidateModel Method

The **ValidateModel** method validates that a model name is recognized or supported by the current provider.

Syntax

object.ValidateModel(*ModelName*)

Parameters

ModelName

A string which specifies the name of the model to validate. This parameter must be provided and cannot be an empty string.

Return Value

A value of **True** is returned if the method succeeds. If the method fails, it will return **False** and the **LastError** property will contain the error code.

Remarks

The **ValidateModel** method verifies that a model name appears to be valid for the current provider. Validation may be performed using locally available information or by querying the provider for a list of supported models. If the provider supports returning model information, this method may perform a lookup to confirm that the specified model name is recognized. This may require a network request and can cause the method to block while the model list is retrieved.

If the provider does not support returning model information, the method only performs basic validation of the model name. For example, it will check the name to ensure it does not contain any illegal characters and uses a format that is common for most service providers. This method is most commonly used to validate user input.

A return value of **True** from this method only indicates that the model name is syntactically valid. It does not guarantee that the selected service provider will accept or allow the model to be used. A provider may reject a valid model name for several reasons, including the model being unavailable for the current account, restricted to specific subscription tiers, region-limited, deprecated, disabled by administrative policy, or not supported by the endpoint being used. Providers may also change model availability over time without notice. Applications should be prepared to handle errors returned when establishing a connection or sending a request, even if the model name was validated successfully.

See Also

[ModelName Property](#), [GetFirstModel Method](#), [GetNextModel Method](#)

ValidateText Method

The **ValidateText** method performs basic validation on a message prompt before it is submitted to a model.

Syntax

object.ValidateText(Prompt)

Parameters

Prompt

A String which contains the prompt to evaluate.

Return Value

A value of **True** is returned if the method succeeds. If the method fails, it will return **False** and the **LastError** property will contain the error code.

Remarks

The **ValidateText** method is intended to help applications detect invalid or malformed input before sending a request to a model. It checks for common problems such as empty strings, text that consists only of spaces or linebreaks, illegal Unicode code points, non-printable characters, and input that appears to contain binary data. This method will return **False** if the string contains embedded null characters.

Applications that accept message text from users or other external sources should validate the text before submitting it to a model. This can help detect malformed or invalid input before a request is sent, reducing the chance of unexpected results or incurring unnecessary usage costs.

This method does not evaluate the quality, safety, or semantic meaning of the message. Although this method is most commonly used to check prompts sent to a model, it can be used to validate any type of text to ensure it is not malformed and contains printable characters.

LlmClient Control Events

Event	Description
OnCancel	Occurs when a pending request has been canceled.
OnConnect	Occurs when a client session has been successfully connected to the provider.
OnDisconnect	Occurs when the client session has been disconnected from the provider.
OnError	Occurs when an error is reported by the control. The event provides the error code and a description of the error.
OnTimeout	Occurs when an operation exceeds the timeout period specified for the control.

OnCancel Event

The **OnCancel** event is generated when a blocking operation is canceled.

Syntax

Sub *object_OnCancel* ([*Index As Integer*])

Remarks

This event occurs when a blocking operation is canceled with the **Cancel** method.

See Also

[Cancel Method](#), [OnError Event](#), [OnTimeout Event](#)

OnConnect Event

The **OnConnect** event is generated when a connection is established.

Syntax

Sub *object_OnConnect* ([*Index As Integer*])

Remarks

The **OnConnect** event is generated when a connection is made with a server as a result of a **Connect** method call.

See Also

[Connect Method](#), [OnDisconnect Event](#)

OnDisconnect Event

The **OnDisconnect** event is generated when a connection is terminated.

Syntax

Sub *object_OnDisconnect* ([*Index As Integer*])

Remarks

The **OnDisconnect** event is generated when the connection is terminated by the server.

See Also

[IsConnected Property](#), [Connect Method](#), [Disconnect Method](#), [OnConnect Event](#)

OnError Event

The **OnError** event is generated when a control error occurs.

Syntax

Sub *object_OnError* ([*Index As Integer*,] **ByVal** *ErrorCode As Variant*, **ByVal** *Description As Variant*)

Remarks

This event occurs when an error occurs during a control action. Errors not generated by the control itself, such as errors related to the programming language or general component errors, do not trigger this event.

The ***ErrorCode*** argument specifies the last error that has occurred. If the error is network related, the error code values returned by the control correspond to those returned by the standard Windows Sockets library.

The ***Description*** argument is a string that describes the error.

See Also

[LastError Property](#), [LastErrorString Property](#), [ThrowError Property](#)

OnTimeout Event

The **OnTimeout** event is fired when a blocking operation times out.

Syntax

Sub *object_OnTimeout* ([*Index As Integer*])

Remarks

The **OnTimeout** event is generated when a blocking operation, such as sending a message prompt or receiving a response, times out.

See Also

[Timeout Property](#), [OnCancel Event](#)

LlmClient Control Constants

Constant	Value	Description
Providers		
llmProviderNone	0	No provider specified
llmProviderLocal	1	Local inference provider (e.g., LM Studio or Ollama)
llmProviderOpenAI	2	OpenAI provider using the ChatGPT models
llmProviderAnthropic	3	Anthropic provider using the Claude models
llmProviderGoogle	4	Google AI provider using the Gemini models
llmProviderMicrosoft	5	Microsoft Foundry provider using OpenAI-compatible models
llmProviderMistral	6	Mistral AI provider using the Mistral models
llmProviderUnknown	-1	Unknown or unrecognized service provider
llmProviderDefault	llmProviderLocal	Default service provider
Options		
llmOptionNone	0	No options specified
llmOptionNoCache	&H0001	Disable provider and model caching for the session
llmOptionKeepAlive	&H0002	Enable persistent (keep-alive) HTTP connections
llmOptionProxy	&H0008	Use a configured proxy server for the connection
llmOptionNoUserAgent	&H0020	Do not send a User-Agent header with the request
llmOptionSecure	&H1000	Force use of a secure (HTTPS) connection
llmOptionDefault	llmOptionNone	Default option set (no flags enabled)
Provider Flags		
llmProviderFlagNone	0	No provider requirements specified
llmProviderFlagRequireTls	&H0001	Requires a secure TLS (HTTPS) connection
llmProviderFlagRequireAuth	&H0002	Requires authentication (e.g., API key or token)
llmProviderFlagApiVersion	&H0004	Requires an explicit API version parameter
llmProviderFlagLocal	&H0008	Locally hosted provider (LM Studio, Ollama, etc.)
llmProviderFlagModelList	&H0010	Supports enumerating available models

llmProviderFlagModelInfo	&H0020	Supports retrieving detailed model information
Model Options		
llmModelOptionDefault	&H0000	Default model filtering (no additional criteria)
llmModelOptionPreview	&H0001	Include preview or experimental models
llmModelOptionStreaming	&H0002	Include models that support streaming responses
llmModelOptionStructured	&H0004	Include models that support structured outputs
llmModelOptionReasoning	&H0008	Include reasoning-oriented models
llmModelOptionVision	&H0010	Include models that support image input
llmModelOptionAudio	&H0200	Include models that support audio output (text-to-speech)
llmModelOptionImage	&H0400	Include models that support image generation or input
llmModelOptionVideo	&H0800	Include models that support video generation
llmModelOptionTranscription	&H1000	Include models that support speech-to-text transcription
llmModelOptionDeprecated	&H8000	Include deprecated or retired models
llmModelOptionAllModels	&HFFFF	Include all available model types
Model Flags		
llmModelFlagNone	&H0000	No model capabilities defined
llmModelFlagChat	&H0001	Supports conversational text generation
llmModelFlagSystemRole	&H0002	Accepts a system role message in the input
llmModelFlagStreaming	&H0004	Supports streaming responses
llmModelFlagStructured	&H0008	Supports structured output (e.g., JSON or schema)
llmModelFlagVision	&H0010	Supports image inputs (multimodal)
llmModelFlagTools	&H0020	Supports tool or function calling
llmModelFlagReasoning	&H0040	Supports reasoning-oriented generation
llmModelFlagResponses	&H0080	Supports the Responses API (unified endpoint)
llmModelFlagFunctions	&H0100	Supports OpenAI-style function calling with schemas
llmModelFlagAudio	&H0200	Supports audio output (text-to-speech)
llmModelFlagImage	&H0400	Supports image generation
llmModelFlagVideo	&H0800	Supports video generation

llmModelFlagTranscription	&H1000	Supports speech-to-text transcription
llmModelFlagInstructions	&H2000	Supports a dedicated instruction field outside message lists
llmModelFlagMaxCompletionTokens	&H4000	Uses max_completion_tokens instead of max_tokens in requests
llmModelFlagInferred	&H80000	Capabilities are inferred rather than explicitly defined
Responses		
llmResponseUnknown	0	No stop reason specified or unrecognized response state
llmResponseComplete	1	Response completed normally
llmResponseLimited	2	Stopped due to token or context limits
llmResponseAborted	3	Request was cancelled or interrupted
llmResponseError	4	An error occurred during processing
llmResponseTimeout	5	Request timed out
Reasoning		
llmReasoningDefault	0	Provider or model default
llmReasoningNone	1	Disable reasoning if available
llmReasoningLow	2	Prefer faster responses; reduces usage costs
llmReasoningMedium	3	Balanced reasoning
llmReasoningHigh	4	Prefer quality responses; increases usage costs
llmReasoningMaximum	5	Maximum reasoning quality
Temperature		
llmTemperatureMinimum	0.0	Deterministic output (minimal randomness)
llmTemperatureConservative	0.3	Low variability, more predictable responses
llmTemperatureBalanced	0.7	Balanced creativity and coherence
llmTemperatureDefault	1.0	Standard default sampling behavior
llmTemperatureCreative	1.2	Increased creativity and variation
llmTemperatureMaximum	2.0	Maximum randomness (highly varied output)
Top-P Sampling		
llmTopPDisabled	0.0	Nucleus sampling disabled
llmTopPMinimum	0.1	Very restrictive token selection
llmTopPConservative	0.8	Conservative token selection
llmTopPBalanced	0.9	Balanced nucleus sampling

llmTopPCreative	0.95	More diverse token selection
llmTopPMaximum	1.0	Full probability distribution (no filtering)
llmTopPDefault	llmTopPDisabled	Default disables nucleus sampling
Top-K Sampling		
llmTopKDisabled	0	Top-K sampling disabled
llmTopKMinimum	0	Equivalent to disabled sampling
llmTopKConservative	10	Restrict to top 10 tokens
llmTopKBalanced	40	Balanced token selection range
llmTopKCreative	60	More diverse token selection
llmTopKMaximum	100	Wide token selection range
llmTopKDefault	llmTopKDisabled	Default disables Top-K sampling
Frequency		
llmFrequencyDisabled	0.0	No frequency penalty applied
llmFrequencyMinimum	0.0	Minimum frequency penalty
llmFrequencyMaximum	2.0	Maximum frequency penalty
llmFrequencyDefault	llmFrequencyDisabled	Default disables frequency penalty
Presence		
llmPresenceDisabled	0.0	No presence penalty applied
llmPresenceMinimum	0.0	Minimum presence penalty
llmPresenceMaximum	2.0	Maximum presence penalty
llmPresenceDefault	llmPresenceDisabled	Default disables presence penalty
Limits		
LlmMaxMessageLength	65536	Maximum length of a single input message (64 KB)
LlmMaxResponseLength	262144	Maximum expected response length (256 KB)
LlmMaxSystemPromptLength	32768	Maximum length of the system prompt (32 KB)
LlmMaxChatHistory	1000	Maximum number of messages stored per session
LlmMaxTokens	200000	Maximum token limit per request

Message History File Format

The **LlmClient** control uses a JSON-formatted message history file to support exporting and importing conversation state between application sessions. This format is used by the **ExportHistory** and **ImportHistory** methods and is intended to provide a simple, human-readable representation of the conversation history associated with a client session.

A message history file contains both the messages sent by the client application and the responses generated by the model. Together, these entries represent the conversational context for the session. The file does not contain information about the client session, aside from the provider type and model name. It does not contain user names, authorization tokens or any information related to the service account.

The history file may contain sensitive or private information, including user prompts, model responses or application-specific data. Applications should take reasonable precautions to protect these files, particularly if they are stored, transmitted or made available for users to download.

The following example shows a simplified message history file containing a single message turn:

```
{
  "version": 1,
  "provider": 1,
  "created": 1715000000,
  "messages": [
    {
      "message": {
        "role": 1,
        "reasoning": 0,
        "flags": 0,
        "id": 1,
        "timestamp": 1715000001,
        "maxTokens": 0,
        "inputTokens": 12,
        "content": "Hello"
      },
      "response": {
        "role": 2,
        "flags": 0,
        "messageId": 1,
        "status": 1,
        "elapsed": 812,
        "timestamp": 1715000002,
        "outputTokens": 24,
        "model": "gpt-5.4-nano",
        "content": "Hi there."
      }
    }
  ],
  "messageCount": 1,
  "model": "gpt-5.4-nano"
}
```

File Structure

A message history file consists of a root JSON object which contains session metadata and an array of message turns.

version

The format version number used by the exported history file.

provider

The numeric **provider identifier** associated with the session.

created

A Unix timestamp value which indicates when the history file was created.

messages

An array containing the exported message turns.

messageCount

The number of message turns stored in the history file.

model

The default model name associated with the exported session.

Message Turns

Each entry in the **messages** array represents a complete message turn consisting of two objects:

- A **message** object which contains the client input
- A **response** object which contains the model output

Applications should not depend on undocumented fields or the exact formatting of exported history files. Future versions of the control may add additional fields or metadata while maintaining compatibility with previous versions where possible.

Remarks

The message history format is intended primarily for exporting, importing and persisting conversation state between application sessions. Although the file format is human-readable JSON text, applications should avoid modifying exported history files unless they fully understand the relationship between the stored values.

Changing values such as the provider identifier, model name, message role or status values may produce undefined or unexpected results when the history is imported. Applications should not modify role identifiers or assume that numeric values used internally by the API will remain unchanged in future versions.

Modifying the message or response content may also invalidate related metadata such as token usage values. For example, changing the **content** field may result in incorrect **inputTokens** or **outputTokens** values being associated with the imported conversation history.

See Also

Large Language Model Providers

One of the first decisions you will need to make when using the SocketTools **LlmClient** ActiveX control is choosing which service provider to use. The control is designed to support a variety of providers and models, and the provider type is specified using one of following provider constants or names. The current version supports the following providers:

Constant	Value	Provider Name	Default Model	Description
<code>llmProviderLocal</code>	1	Local	None	Locally hosted models using servers like LM Studio or Ollama. This is ideal for development, testing, offline use, or avoiding usage costs. A wide range of open-source models are available; for best results, start with smaller instruction-tuned models such as qwen2.5-7b-instruct , llama-3.2-3b-instruct , or mistral-7b-instruct .
<code>llmProviderOpenAI</code>	2	OpenAI	gpt-5.4-nano	OpenAI's public API (ChatGPT) is a recommended starting point for most developers due to ease of use, strong general performance, and comprehensive documentation. For initial development and testing, lightweight models such as the GPT-5 mini series provide fast response times and lower usage costs.
<code>llmProviderAnthropic</code>	3	Anthropic	claude-haiku-4-5	Anthropic's Claude models are well suited for structured reasoning, conversational clarity, and safety-focused applications. For initial use, the Haiku models offer lower cost and faster response times while maintaining strong performance.
<code>llmProviderGoogle</code>	4	Google	gemini-2.5-flash	Google's Gemini models are a good choice for multimodal applications and integration with the Google AI ecosystem. The Flash models are recommended for getting started due to their lower latency and reduced token costs.
<code>llmProviderMicrosoft</code>	5	Microsoft	None	Microsoft Foundry OpenAI-compatible models are typically used in enterprise environments

				requiring Azure integration and regional deployment control. This option requires provisioning a model deployment within Foundry and specifying the deployment name and API version when connecting.
llmProviderMistral	6	Mistral	mistral-small-3.2	Mistral AI models provide efficient and cost-effective options for general-purpose and reasoning tasks. Smaller models are recommended when getting started due to their performance and lower cost.

To select a provider, you can either set the **Provider** or **ProviderName** property. The **Provider** property uses one of the numeric constants, such as **llmProviderOpenAI**. The **ProviderName** property accepts a String value which can be one of the names listed above, such as **"OpenAI"**. You can use either property, and changing the value of one will automatically change the value of the other. It's a matter of personal preference if you wish to use a provider name or a predefined numeric constant in your code.

Choosing a Model

Although SocketTools provides a default model for most providers, the model names and availability will change over time. The providers which do not have a default model assigned to them will always require a specific model name when establishing the connection. Some providers, notably Microsoft Foundry and locally hosted services, will explicitly require you to provide a model name to establish a connection.

It is important to note that the control is not limited only to those default models listed above. Developers are encouraged to enumerate available models and explicitly select a model that meets their requirements. The control provides methods designed to return information about all of the compatible models supported by a provider. For more information refer to the [GetFirstModel](#) and [GetNextModel](#) methods.

Most language model providers offer multiple models with different capabilities, performance characteristics, and pricing. Rather than selecting a specific model name immediately, it is often more useful to choose a general category of model based on your application's needs.

Common model categories include:

- **Lightweight.** Optimized for speed and low cost. These are ideal for simple tasks such as formatting, summarization, classification, or user interface interactions where responsiveness is important. These are the default models assigned to supported providers. In most cases, we recommend you start with a lightweight model until you determine your application could benefit from a more capable model type.
- **Balanced.** General purpose models that provide good performance across a wide range of tasks. These are typically the best default choice for most applications which need to balance between performance and capability. Examples are **gpt-5-mini**, **claude-sonnet-4-6**, **gemini-3.1** and **mistral-medium** models.
- **Reasoning.** Designed for more complex tasks such as multi-step problem solving, analysis, and code generation. These models may produce more detailed responses but typically use more

tokens and have higher latency and increased costs. Examples are **gpt-5**, **claude-opus-4-7**, **gemini-3.1-pro** and **mistral-large** models.

- **Multimodal.** Support input or output beyond plain text, such as images, audio, or structured data. These are useful when working with media content or advanced integrations.

In most cases, developers should begin with a lightweight or balanced model and only move to more advanced models when additional capability is required. The exact model names and capabilities will vary between providers, but these categories provide a useful framework for selecting an appropriate model. Applications should also avoid relying on strict token limits or attempting to precisely manage context usage. Providers ultimately determine request limits, and applications should be prepared to handle responses that are truncated or rejected when limits are exceeded.

API Keys and Authentication

Most language model providers require an API key (or authentication token) to access their services. An API key is a unique identifier associated with your account that is included with each request to authenticate the client and track usage.

When using the **LlmClient** control, the API key is typically provided by either setting the **ApiKey** property or when establishing a session using the **Connect** method. The control will include this key in requests to the selected provider using the appropriate authentication mechanism.

Because API keys grant access to external services and may incur usage charges, they should be handled carefully and not exposed unnecessarily. The control supports several methods for providing API keys, allowing applications to balance convenience and security.

Providing an API Key

The control supports the following methods for supplying an API key:

- **Literal string**
The API key can be provided directly as a string when creating a session. This is the simplest approach and is often used for testing or development, but it is not recommended for production applications because the key may be exposed in application binaries or source code.
- **Environment variable**
The API key can be stored in an environment variable and retrieved at runtime. This approach avoids embedding the key directly in the application and is commonly used in development environments, scripts, or deployment pipelines.
- **Windows Credential Manager**
The API key can be stored securely using the Windows Credential Manager and retrieved by the application at runtime. This is the recommended approach for Windows applications because it provides secure storage and helps prevent accidental exposure of sensitive credentials.

Best Practices

- Do not embed API keys directly in source code for production applications.
- Use secure storage mechanisms, such as the Windows Credential Manager, whenever possible.
- Limit access to API keys and avoid sharing them between applications or users.
- Review provider usage policies and configure usage limits or alerts where available.

Each provider has its own process for creating and managing API keys. Refer to the provider

documentation for details on generating keys, rotating credentials, and managing access.

Application Design

When designing an application that uses a language model provider, developers generally have two approaches for managing API keys:

- **Application-managed API key**

The developer provides an API key that is used by the application for all requests. This approach is simple to implement and provides a consistent user experience, but the developer is responsible for all usage and any associated costs.

- **User-provided API key (Bring Your Own Key)**

The application allows the end user to supply their own API key, typically through a configuration dialog or settings interface. In this case, the user is responsible for usage and costs, and the application acts as a client using the user's credentials.

Each approach has trade-offs. Using an application-managed key simplifies the user experience but may require safeguards such as rate limiting or usage monitoring. Allowing users to provide their own key can reduce operational costs and provide greater flexibility, but requires additional user interface considerations and clear instructions for obtaining and configuring API access.

Applications intended for a broad audience often prefer a built-in API key for ease of use, while developer-focused tools frequently support user-provided keys for flexibility.

Provider Overview

The following sections provide more detailed information about the supported providers. One of the advantages of the **LlmClient** control is that applications are not limited to a single language model service. Different providers may offer advantages related to pricing, performance, regional availability, deployment flexibility, or model capabilities.

Supporting multiple providers can also provide greater flexibility for end users. Some users or organizations may already have existing accounts, billing arrangements, or infrastructure associated with a specific provider such as OpenAI, Google, Microsoft Foundry, or a locally hosted inference service. Applications can allow users to select the provider and model which best meets their requirements without requiring significant changes to application logic.

Local

The **llmProviderLocal** provider type is used for locally hosted language model inference. This is particularly useful for development, testing, and experimentation without relying on a cloud-based provider. Local hosting allows developers to evaluate model behavior, test integrations, and work offline or within a private environment. This requires you to install and configure an application on your local system or network which will provide the inference service. For the Windows platform, we recommend one of the following applications, which are free to install and use.

LM Studio

LM Studio provides a full-featured desktop environment for running and testing language models locally. It includes model management, a built-in server, and support for OpenAI-compatible APIs, making it a strong choice for development and evaluation.

- [LM Studio](#) 
- [LM Studio Documentation](#) 

Ollama

Ollama is a lightweight local model runtime that makes it easy to download and run models on a local system. It provides a simple API interface and is well suited for basic testing and self-hosted deployments.

- [Ollama](#) 
- [Ollama Documentation](#) 

OpenAI

The **11mProviderOpenAI** provider connects to OpenAI's public API and is generally the recommended starting point for most developers. It offers a wide range of well-documented models, consistent API behavior, and strong general-purpose performance. Developers who are new to using large language models or want a reliable default should typically begin here.

To get started, developers create an API key, select a model name, and connect to the default OpenAI endpoint. The API is widely supported and serves as the baseline for compatibility with many other providers.

- [OpenAI Platform](#) 
- [OpenAI Documentation](#) 
- [Manage API Keys](#) 

Anthropic

The **11mProviderAnthropic** provider connects to Anthropic's Claude API, which focuses on conversational models designed for safety and structured reasoning. Developers must create an API key and select a supported Claude model. The API is similar in concept to OpenAI but uses its own endpoints and request formats.

- [Anthropic](#) 
- [Claude Documentation](#) 

Google

The **11mProviderGoogle** provider connects to Google's Gemini API, which provides access to multimodal models and integrates with the broader Google AI ecosystem. Developers typically obtain an API key through Google AI Studio and use it to authenticate requests to the Gemini service.

- [Google AI](#) 
- [Google Documentation](#) 

Microsoft

The **11mProviderMicrosoft** provider connects to a Microsoft Foundry OpenAI-compatible deployment. This option is often used in enterprise environments where Azure integration, regional deployment, or Microsoft-managed infrastructure is required. Unlike the public OpenAI API, Microsoft requires a resource-specific endpoint, a deployment name instead of a direct model name, and an explicit API version. Authentication is typically performed using an API key.

- [Microsoft Foundry](#) 
- [Azure OpenAI Reference](#) 

Mistral

The **11mProviderMistral** provider connects to Mistral AI's hosted API service. Mistral models are designed to provide strong general-purpose and reasoning performance while maintaining efficient

resource usage and competitive pricing. Developers who want a balance between capability, response speed, and lower operational cost may find these models to be a good alternative to larger commercial providers. Some organizations may prefer Mistral AI due to regional deployment considerations or compatibility with European-based infrastructure and services.

Mail Message Control

Compose and parse standard MIME formatted email messages.

Reference

- [Properties](#)
- [Methods](#)
- [Events](#)
- [Error Codes](#)

Control Information

Object Name	MailMessageCtl.MailMessage
File Name	CSMSGX12.OCX
Version	12.0.3024.1286
ProgID	SocketTools.MailMessage.12
ClassID	65A25CF7-655D-4223-869A-3CDBBC4FE934
Threading Model	Apartment
Help File	CST12CTL.CHM
Dependencies	None
Standards	RFC 822, RFC 2045, RFC 2046, RFC 2047, RFC 2048

Overview

The Mail Message ActiveX control provides an interface for composing and processing email messages and newsgroup articles which are structured according to the Multipurpose Internet Mail Extensions (MIME) standard. Using this control, an application can easily create complex messages which include multiple alternative content types, such as plain text and styled HTML text, file attachments and customized headers.

It is not required that the developer understand the complex MIME standard; a single method can be used to create multipart message, complete with a styled HTML text body and support for international character sets. The Mail Message control can be easily integrated with the other mail related components, making it extremely easy to create and process MIME formatted messages.

The control also includes an interface for managing a local message storage file that can be used to store and retrieve multiple messages. Methods are provided to open and create storage files, add, remove and extract messages from storage, and search the stored messages for specific header field values.

Requirements

The SocketTools ActiveX Edition components are self-registering controls that are compatible with any programming language that supports the Component Object Model (COM) and the ActiveX control specification. If you are using Visual Basic 6.0, Service Pack 6 (SP6) is required. We recommend installing all available updates for your development tools. Although the Visual Basic 6.0 runtime is supported on Windows 11, the IDE itself is no longer officially supported by Microsoft. Legacy IDEs and compilers may also require elevated (administrator) privileges to run properly.

The ActiveX controls are supported on Windows 7, Windows Server 2008 R2, and later versions of both desktop and server editions of Windows. For Windows 7, Service Pack 1 (SP1) is the minimum requirement. For Windows 8 systems, the 8.1 update must be installed. On ARM-based platforms, the minimum supported version is Windows 10 build 1709.

SocketTools includes components for both 32-bit (x86) and 64-bit (x64) Windows platforms. All modern versions of Windows are 64-bit, but we continue to include 32-bit components for compatibility with legacy development tools such as Visual Basic 6.0. We also provide native ARM64 ActiveX controls for systems running Windows on ARM. Note that 32-bit applications on ARM run using x86 emulation, and Microsoft no longer supports native ARM32 applications.

If you are using VBScript, Visual Basic for Applications (VBA), or another scripting environment on an ARM-based system, be aware that 64-bit hosts will require ARM64 components, while 32-bit hosts will use x86 components under emulation. This includes applications created with Visual Basic 6.0. To reduce deployment complexity and avoid confusion, SocketTools does not include ARM32 ActiveX controls in its standard redistribution packages but they are available on request for legacy or specialized scenarios.

Distribution

When you distribute an application that uses this control, you can either install the file in the same folder as your application executable or as a shared component in the appropriate system folder. If you install the control in the system folder, it is important that you distribute the correct version for the target platform and it must be registered. If you install the control in the same folder as your executable, it is recommended that you use registration-free activation or COM redirection to ensure that the correct version of the control is loaded by the application.

Mail Message Control Properties

Property	Description
AllHeaders	Returns the complete RFC 822 header values for the current message
AllRecipients	Returns a comma-separated list of all message recipients
Attachment	Gets and sets the name of the current file attachment
Authentication	Gets the authentication results for the current message
Bcc	Gets and sets the blind carbon-copy header field value
Boundary	Returns the boundary string used to separate parts in a multipart message
Cc	Gets and sets the carbon-copy header field value
ContentID	Return the content identifier for the selected message part
ContentLength	Returns the size of the data stored in the selected message part
ContentType	Gets and sets the content type of the selected message part
Date	Gets and sets the date for the current message
Encoding	Gets and sets the content encoding method used for the current message part
Filter	Gets and sets the flags used to filter text content in the message
FilteredText	Returns filtered text in the current message part
From	Gets and sets the address of the user who sent the message
HeaderField	Gets and sets the current header field name
HeaderValue	Gets and sets the value of the specified header field
LastError	Gets and sets the last error that occurred on the control
LastErrorString	Return a description of the last error to occur
Link	Returns a hyperlink found in the current message part
LinkCount	Returns the number of hyperlinks found in the current message part
Localize	Enable or disable message localization
Mailer	Gets and sets the name of the mailer application
Message	Gets and sets the current message headers and body
MessageID	Return the current message identifier
MimeVersion	Gets and sets the MIME version number for the current message
Organization	Gets and sets the name of the organization that originated the message
Part	Gets and sets the current message part
PartCount	Return the number of parts in the current message
Priority	Gets and sets the current message priority
Recipient	Returns the address of a message recipient

Recipients	Returns the number of recipients specified in the current message
ReplyTo	Gets and sets the address of the user who should receive replies to this message
SelLength	Gets and sets the current message body text selection length
SelStart	Gets and sets the starting position of the current message body text selection
SelText	Gets and sets the selected message body text
Sender	Gets and sets the address of the user who originated the message
StoreCount	Gets the number of messages in the current storage file, not including deleted messages
StoreFile	Gets and sets the name of the file used to store messages
StoreIndex	Gets and sets the current message index for the current storage file
StoreSize	Gets the total number of messages in the current storage file, including deleted messages
Subject	Gets and sets the subject of the current message
ThrowError	Enables or disables error handling by the application
TimeZone	Gets and sets the current timezone offset in seconds
Text	Gets and sets the body of the current message part
TextLength	Gets the number of characters in the body of the current message part
To	Gets and sets the address of the message recipient
Version	Return the current version of the control

AllHeaders Property

Returns the complete RFC 822 header values for the current message.

Syntax

object.AllHeaders

Remarks

The **AllHeaders** property will return all of the RFC 822 header values in a string. This includes the message headers that are most commonly referred to, such as the To, From and Subject headers. Each header and its value are separated by a colon, and terminated with a carriage return and linefeed (CRLF) pair.

The headers and their values returned by this property will not be identical to the header block in the original message. If a header value is split across multiple lines, the text returned by this property will be folded, with the complete header value on a single line of text and removing any extraneous whitespace. If the header value has been encoded by the mail client, this property will return the decoded value, not the original encoded value.

Data Type

String

See Also

[HeaderField](#), [HeaderValue](#), [GetHeader](#), [SetHeader](#)

AllRecipients Property

Returns a comma-separated list of all message recipients.

Syntax

object.AllRecipients

Remarks

The **AllRecipients** property returns a string value that contains a comma-separated list of all message recipients. To individually enumerate through each of the recipient addresses, you can use the **Recipient** property array and **Recipients** property.

The string returned by this property will include those addresses specified by the **Bcc** property, even though they are not included in the message header.

Data Type

String

See Also

[Bcc Property](#), [Cc Property](#), [Recipient Property](#), [Recipients Property](#), [To Property](#), [Compose Method](#)

Attachment Property

Gets and sets the name of the current file attachment.

Syntax

object.Attachment [= *filename*]

Remarks

The **Attachment** property specifies the name of the file attachment in a multipart message. When a new part is selected that contains an attached file, the **Attachment** property is updated to reflect the attached file's name.

This property is used by the attach and extract actions to specify the local file name that will be used. Changing its value does not change the attached file name in the multipart message itself.

Data Type

String

See Also

[Boundary Property](#), [FileName Property](#), [AttachFile Method](#), [ExtractFile Method](#), [FindAttachment Method](#)

Authentication Property

Return the authentication results for the current message based on the **Authentication-Results** header value.

Syntax

object.Authentication

Remarks

Modern email systems use a set of authentication mechanisms to help verify that a message was sent from a legitimate source and not forged by a spammer or attacker. The **Authentication** property enables you to easily determine which of these mechanisms have passed a check and which of them have failed. It evaluates the following authentication information reported by the mail server:

SPF
Sender Policy Framework allows the owner of a domain to specify which mail servers are authorized to send email on its behalf. If the sending server is not listed in the domain's SPF record, the message may be marked as suspicious. SPF helps prevent spoofing of the envelope sender address, which is often used in phishing attacks.

DKIM
DomainKeys Identified Mail uses public-key cryptography to sign specific parts of the email, such as headers and body content. The signature is added by the sending mail server, and receiving systems use DNS to retrieve the sender's public key to verify that the message has not been tampered with. A valid DKIM signature helps confirm that the message was truly sent by the claimed domain.

DMARC
Domain-based Message Authentication, Reporting, and Conformance builds on SPF and DKIM by defining a policy for how a domain wants email receivers to handle messages that fail authentication checks. It also ensures that the visible From: address matches the domain that passed SPF or DKIM (a concept called alignment). DMARC allows domain owners to monitor abuse and enforce stronger protection against spoofing.

Checking these authentication results can help identify spoofed or forged messages, improve filtering decisions, and increase overall mail security. While not every legitimate message will have all three, failure of all mechanisms, especially from domains that publish strict DMARC policies, should be treated as suspicious.

This property returns one or more bitflags based on the authentication results for the current message. The following flags are defined:

Value	Description
mimeAuthNone	The message does not contain an Authentication-Results header or does not include any recognizable authentication types and their associated results.
mimeAuthSpfPassed	The message passed the Sender Policy Framework (SPF) check. The sender's IP address was authorized to send mail for the domain in the envelope sender address.
mimeAuthSpfFailed	The message failed the SPF check. The sending mail server is not authorized by the domain's SPF record to send mail on its behalf.

mimeAuthDkimPassed	The message passed the DomainKeys Identified Mail (DKIM) check. The signature applied by the sender was successfully verified using the domain's public key.
mimeAuthDkimFailed	The message failed the DKIM check. The signature could not be verified or did not match the message content, suggesting it may have been altered.
mimeAuthDmarcPassed	The message passed DMARC evaluation. The message aligned with a valid SPF or DKIM result based on the sender domain's policy.
mimeAuthDmarcFailed	The message failed DMARC evaluation. It did not pass SPF or DKIM checks in a way that aligns with the domain's published policy.
mimeAuthTempError	A temporary error occurred while evaluating one or more authentication mechanisms. This may indicate a DNS lookup timeout or other transient failure.
mimeAuthPermError	A permanent error occurred during authentication checks. This may indicate a malformed DNS record or invalid message structure that prevents proper evaluation.

While these authentication methods are useful signals, failing one of them does not necessarily mean a message is malicious. Many legitimate messages, even from well-known companies, may have misconfigured SPF records, missing DKIM signatures, or inconsistent DMARC policies. Conversely, a message that passes all checks could still be unwanted or deceptive. These results should be treated as advisory signals rather than absolute indicators of legitimacy. Developers are encouraged to consider authentication status alongside other factors, such as message content, sender reputation, and user reporting.

To simplify checking authentication outcomes, the following predefined flag combinations are also available:

- mimeAuthPassed is a combination of all passing results (SPF, DKIM, DMARC).
- mimeAuthFailed is a combination of all failing results.
- mimeAuthError is a combination of temporary or permanent errors.

Data Type

Integer (32-bit)

See Also

[Filter Property](#), [FilteredText Property](#), [Link Property Array](#), [LinkCount Property](#), [GetHeader Method](#)

Bcc Property

Gets and sets the blind carbon-copy header field value.

Syntax

object.Bcc [= *addresses*]

Remarks

The **Bcc** property returns the list of addresses that are to receive blind carbon copies of the message. Setting the property creates or modifies the Bcc header field. Multiple addresses can be specified by separating them with commas.

A blind carbon copy is when a copy of a message is delivered to a recipient, but that recipient is not listed in the message headers. Because the other recipients of that same message will not see the address in the headers, they will not know it was delivered to that person. As a result, the Bcc header field is not normally exported when the **Export** method is called, or when the contents of the message are referenced using the **Message** property. To include the Bcc header in the message, use the **mimeOptionAllHeaders** option. Of course, if this option is specified, the addresses in the Bcc list will no longer be blind to the other recipients.

Data Type

String

See Also

[Cc Property](#), [From Property](#), [Message Property](#), [Recipient Property](#), [Recipients Property](#), [ReplyTo Property](#), [Sender Property](#), [To Property](#), [Export Method](#)

Boundary Property

Returns the boundary string used to separate parts in a multipart message.

Syntax

object.Boundary

Remarks

The Boundary property returns the current boundary string being used in a multipart message. When the control is used to create a multipart message, a unique boundary string is created and the Boundary property is updated to reflect it's value.

Data Type

String

See Also

[Attachment Property](#), [AttachFile Method](#), [ExtractFile Method](#)

Cc Property

Gets and sets the carbon-copy header field value.

Syntax

object.Cc [= *addresses*]

Remarks

The **Cc** property returns the list of addresses that were delivered carbon copies of the message. Setting the property creates or modifies the Cc header field. Multiple addresses can be specified by separating them with commas.

Data Type

String

See Also

[Bcc Property](#), [From Property](#), [ReplyTo Property](#), [Sender Property](#), [To Property](#)

ContentID Property

Return the content identifier for the selected message part.

Syntax

object.ContentID

Remarks

The **ContentID** property returns the unique content identifier string for the current message part. This multipart header field is not commonly used, and if undefined, will return an empty string.

Data Type

String

See Also

[ContentLength Property](#), [ContentType Property](#)

ContentLength Property

Returns the size of the data stored in the selected message part.

Syntax

object.ContentLength

Remarks

The **ContentLength** property returns the size of the content in the current message part as the number of bytes and does not account for any Unicode conversion of text. Exercise caution when using this property to determine the size of a buffer that should be allocated for the message text. If you need to know the actual length of the decoded text in the current message part, use the **TextLength** property instead. It will return the number of characters (not bytes) in the message after it has been decoded and converted to Unicode.

This property is read-only, and is updated when the current message part changes.

Data Type

Integer (Int32)

See Also

[ContentID Property](#), [ContentType Property](#), [Part Property](#), [Text Property](#), [TextLength Property](#)

ContentType Property

Gets and sets the content type of the selected message part.

Syntax

`object.ContentType [= value ]`

Remarks

The **ContentType** property returns the MIME type for the currently selected message part. The type string consists of a primary type and secondary sub-type separated by a slash, followed by one or more optional parameters delimited by semi-colons. For example, this is a common content type for text messages:

`text/plain; charset=utf-8`

The **text** designation indicates that this message part contains readable text, and the **plain** sub-type indicates that the text does not contain any special encoding. The optional parameter which follows the content type provides additional information about the content. In this example, it specifies which character set should be used to display the text. The two common character sets used are UTF-8 and US-ASCII.

There are seven predefined, standard content types, each with their own sub-types. The following table lists these types, along with some common sub-types that are found in messages:

Type	Sub-Types	Description
text	plain, richtext, html	Indicates that the message part contains text. This is the most common type found in mail messages; if no content type is explicitly defined, then it is assumed to be plain text
image	gif, jpeg	Indicates that the message part contains a graphics image
audio	basic, aiff, wav	Indicates that the message part contains audio data; the basic sub-type is 8-bit PCM encoded audio (commonly found with the .au filename extension)
video	mpeg, avi	Indicates that the message part contains a video clip in the specified format
application	octet-stream, postscript	Indicates that the message part contains application specific data, typically used with the octet-stream sub-type to indicate binary file attachments for executable programs, compressed file archives, etc.
message	rfc822	Indicates that the message part contains a complete RFC 822 compliant message, complete with headers
multipart	mixed, alternative	Indicates that this is part of a mixed message (a message that contains multiple parts of different content types)

The three most common content types that are used in applications are text/plain for the mail message body, application/octet-stream for binary file attachments and multipart/mixed for messages that contain both text and attached files. For more information about the different content types, refer to the Multipurpose Internet Mail Extensions (MIME) standards document RFC 1521.

Data Type

String

See Also

[ContentID Property](#), [ContentLength Property](#)

Date Property

Gets and sets the date for the current message.

Syntax

object.Date [= *date*]

Remarks

The **Date** property returns the value of the date field in the current message header. Setting this property causes the date field to be updated with the specified value. When setting the date, any one of the following formats may be used:

Format	Example
mm/dd/yy[yy] hh:mm[:ss]	03/01/1998 12:00:00
yy[yy]/mm/dd hh:mm[:ss]	97/03/01 12:00:00
dd mmm yy[yy] hh:mm[:ss]	01 Mar 1998 12:00:00
mmm dd yy[yy] hh:mm[:ss]	Mar 01 1998 12:00:00

Any extraneous information that may be included in the date string, such as the day of the week, is ignored. In addition to the date and time, the string may also include a time zone specification at the end. If no time zone is specified, the current time zone is used.

When specifying a time zone, the value should either be prefixed by a plus sign (+) to indicate that the time zone is to the east of GMT, or a minus sign (-) to indicates that it's to the west. Four digits follow, with the first two indicating the number of hours east or west of GMT, and the last two digits indicating the number of minutes. Therefore, a value of -0800 means that the time zone is eight hours to the west of GMT, or in other words, the Pacific time zone.

Regardless of the format of the string assigned to the property, it always returns the date in the same format (which conforms to the RFC 822 specification). Using the above examples, the date would be returned as "Sat, 01 Mar 1998 12:00:00 -0800".

The **Localize** property affects how dates are processed by the control. If enabled, dates are automatically adjusted for the local time zone. By default, localization is disabled.

Data Type

String

See Also

[Localize Property](#), [TimeZone Property](#)

Encoding Property

Gets and sets the content encoding method used for the current message part.

Syntax

`object.Encoding [= value ]`

Remarks

The **Encoding** property returns the method used for encoding the current message part. Setting this property causes the Content-Transfer-Encoding header value to be updated. The following values are commonly used:

Type	Description
7bit	The default transfer encoding type, which consists of printable ASCII characters.
8bit	Printable ASCII characters, including those characters with the high-bit set (as is common with the ISO Latin-1 character set); this encoding type is not commonly used.
binary	All characters; binary transfer encoding is rarely used.
quoted-printable	Printable ASCII characters, with non-printable or extended characters represented using their hexadecimal equivalents.
base64	The transfer encoding type commonly used to convert binary data into 7-bit ASCII characters so that it may be transported safely through the mail system.
x-uuencode	A transfer encoding type similar in function to the base64 encoding method.

Note that setting this property only updates the Content-Transfer-Encoding header value. To control the actual encoding method used for attachments, specify the encoding method when calling the **AttachFile** method.

Data Type

String

See Also

[Attachment Property](#), [ContentLength Property](#), [ContentType Property](#), [ExtractFile Method](#), [AttachFile Method](#)

FileName Property

Gets and sets the name of the file that contains the message to be processed

Syntax

object.FileName [= *filename*]

Remarks

The **FileName** property returns the name of the file that contains the message being processed. Setting this property specifies the name of a file that contains a MIME message, and is used in conjunction with the methods used to import and export messages.

Data Type

String

See Also

[AttachFile Method](#), [Export Method](#), [ExtractFile Method](#), [Import Method](#)

Filter Property

Gets and sets the flags used to filter text content in the message.

Syntax

`object.Filter [= value ]`

Remarks

The **Filter** property specifies one or more bitflags which controls what the **FilteredText** property returns. This can be used to explicitly include or exclude certain content from the filtered text, such as insecure URLs or Unicode text. The following flags are supported:

Value	Description
<code>mimeFilterDefault</code>	Perform default filtering which removes HTML markup and decodes HTML entities. No additional filtering of URLs or text is performed.
<code>mimeFilterRemoveQuery</code>	Remove query parameters from hyperlinks such as <code>?id=123</code> . Useful for stripping tracking information or session data.
<code>mimeFilterRemoveCredentials</code>	Remove embedded user credentials in URLs such as <code>user:pass@example.com</code> , preventing obfuscation or accidental disclosure.
<code>mimeFilterRemoveLinks</code>	Remove all hyperlinks from the message content. This includes both anchor tags in HTML and plain text URLs.
<code>mimeFilterRemoveUnicode</code>	Strip all non-ASCII (Unicode) characters from the message. Use this when only 7-bit clean output is required.
<code>mimeFilterRejectLocal</code>	Reject any link that refers to internal or local domains, including <code>.local</code> , <code>.lan</code> , and <code>localhost</code> .
<code>mimeFilterRejectIP</code>	Reject links that use raw IP addresses instead of hostnames, such as <code>http://192.168.1.1</code> .
<code>mimeFilterRejectPunycode</code>	Reject hyperlinks using Punycode-encoded domain names, such as those with the <code>xn--</code> prefix. This helps prevent spoofing using visually similar characters.
<code>mimeFilterRejectHttp</code>	Reject any hyperlinks that use <code>http://</code> instead of the secure <code>https://</code> protocol.
<code>mimeFilterRejectUnsafe</code>	Reject links using unsafe schemes such as <code>file:</code> , <code>data:</code> , or <code>javascript:</code> . These links are excluded by default unless overridden.
<code>mimeFilterAllowPunycode</code>	Explicitly permit Punycode domain names in URLs even when <code>mimeFilterRemoveUnicode</code> is specified. Use when legitimate IDN domains are expected.
<code>mimeFilterAllowUnsafe</code>	Allow potentially unsafe schemes such as <code>file:</code> or <code>javascript:</code> in message content. Use with caution and only when the message source is fully trusted.

mimeFilterStrict	A combination of values which removes unsafe content, stripping insecure links, query parameters and credentials from URLs. This is the recommended value for maximum safety, filtering potentially malicious or misleading content from the current message part.

Data Type

Integer (Int32)

See Also

[FilteredText Property](#), [Text Property](#), [TextLength Property](#), [NormalizeText Method](#)

FilteredText Property

Gets the filtered version of the text in the current message part.

Syntax

object.Text [= *value*]

Remarks

The **FilteredText** property returns filtered text for the current message part, removing any HTML tags and potentially unsafe content. It handles both HTML and plain text content types. For HTML, the markup is converted to plain text and decodes HTML entities. For plain text, it scans for embedded URLs and applies filtering based on the options specified with the **Filter** property. If the current message part does not contain text (for example, if the current message part is a file attachment), this property will return an empty string.

When filtering HTML markup from message content, this property changes it in the following ways:

- Removes script, style, and other non-visible or unsafe elements.
- Converts common tag structures, such as lists and headers, into readable plain text.
- Extracts and optionally filters or removes hyperlinks and image alt text.
- Decodes common HTML entities such as **&trade** and **&copy**, as well as numeric entites like **&#x20**.

The property is designed to return clean, human-readable output suitable for previewing message contents in text-only environments, logging, or performing further analysis. It ensures that embedded credentials, tracking links, or insecure resources are removed or sanitized based on filtering preferences.

By default, this property will not remove Unicode characters or strip links unless explicitly instructed via flags by setting the **Filter** property. The **mimeFilterStrict** constant is a recommended combination for maximum safety and removes potentially malicious or misleading elements.

To obtain the original message content for the current message part, use the **Text** property.

If you wish to normalize any text, not simply the text in the current message part, you can use the **NormalizeText** method. This performs multi-stage normalization on a string or byte array provided as an argument. It is important to note that the **NormalizeText** method is much stricter with how it validates the input and is designed to throw an exception on malformed text rather than filter it out.

Data Type

String

See Also

[Filter Property](#), [Text Property](#), [TextLength Property](#), [NormalizeText Method](#)

From Property

Gets and sets the address of the user who sent the message.

Syntax

object.From [= *address*]

Remarks

The **From** property returns the address of the user who sent the message. Setting the property causes the From header field to be updated with the new value.

Data Type

String

See Also

[Bcc Property](#), [Cc Property](#), [ReplyTo Property](#), [Sender Property](#), [To Property](#)

HeaderField Property

Gets and sets the current header field name.

Syntax

object.HeaderField [= *header*]

Remarks

The **HeaderField** property returns the name of the current header field. Setting this property causes the control to determine if that header field exists, and if it does, to update the **HeaderValue** property with its value. This property can be used to obtain the value of any header in the current message part, and in conjunction with the **HeaderValue** property, can be used to create new headers.

Data Type

String

See Also

[AllHeaders Property](#), [HeaderValue Property](#), [GetHeader Method](#), [SetHeader Method](#)

HeaderValue Property

Gets and sets the value of the specified header field.

Syntax

object.HeaderValue [= *value*]

Remarks

The **HeaderValue** property returns the value of the header specified by the **HeaderField** property. Setting this property updates the specified header value. If the **HeaderField** property refers to a header field that does not exist, then it is created in the current message part.

Data Type

String

See Also

[AllHeaders Property](#), [HeaderField Property](#), [GetHeader Method](#), [SetHeader Method](#)

LastError Property

Gets and sets the last error that occurred on the control.

Syntax

object.LastError [= *value*]

Remarks

The **LastError** property can be read to determine the last error that occurred for this control. If a value is assigned to this property, it must either be zero to clear the error or a valid error code for the control.

Data Type

Integer (Int32)

See Also

[LastErrorString Property](#), [OnError Event](#)

LastErrorString Property

Return a description of the last error to occur.

Syntax

object.LastErrorString

Remarks

The **LastErrorString** property returns a description of the last error that occurred. This can be used to display a meaningful error message to a user, rather than just the numeric value returned by the **LastError** property.

Data Type

String

See Also

[LastError Property](#), [OnError Event](#)

Link Property

Returns a hyperlink found in the current message part.

Syntax

object.Link(Index)

Remarks

The **Link** property array is used to enumerate the hyperlinks which were found in the current message part. This property array is zero based, meaning that the first index value is zero. The total number of links in the current message part can be determined by checking the value of the **LinkCount** property.

The message contents are decoded and converted to UTF-8 before searching for matching links. If the message content uses HTML markup, it is possible for this property to return links in the HTML header as well as the body. Messages which are composed using Outlook will typically have links to XML namespaces like <http://www.w3.org/TR/REC-html40>.

This property can only be used to extract links from message text and cannot be used with file attachments or encoded binary data. For example, if the current message part contains encoded image data, the **LinkCount** property will return zero. Links which do not reference files, such as **mailto:** or **data:** will be ignored when searching the message.

Data Type

String

See Also

[LinkCount Property](#), [Part Property](#), [Text Property](#)

LinkCount Property

Returns the number of links found in the current message part.

Syntax

object.Links

Remarks

The **LinkCount** property returns the number of hyperlinks found in the current message part. This property can be used in conjunction with the **Link** property array to enumerate all of the links found in the message.

Data Type

Integer (Int32)

See Also

[Link Property](#), [Part Property](#), [PartCount Property](#), [Text Property](#)

Localize Property

Enable or disable message localization.

Syntax

object.**Localize** [= { True | False }]

Remarks

The **Localize** property is used to enable or disable localization features of the control. Currently this only affects the way in which dates are processed by the control. If set to True, the control will adjust for the local time zone when setting and reading the **Date** property. The default value for this property is False.

Data Type

Boolean

See Also

[Date Property](#), [TimeZone Property](#)

Mailer Property

Gets and sets the name of the mailer application.

Syntax

object.**Mailer** [= *program*]

Remarks

The **Mailer** property returns the value of the X-Mailer field in the current message header. Setting this property causes the field to be updated with the specified value. This is typically used to identify the program which generated the message.

Data Type

String

See Also

[HeaderField Property](#), [HeaderValue Property](#), [GetHeader Method](#), [SetHeader Method](#)

Message Property

Gets and sets the current message headers and body.

Syntax

object.**Message** [= *value*]

Remarks

The **Message** property returns the current message, including the headers and all message parts, as a string. Setting this property will cause the current message to be cleared and replaced by the new value. The string contents must follow the standard specifications for a message. If the property is set to an empty string, the current message is cleared.

Data Type

String

See Also

[Text Property](#), [Export Method](#), [Import Method](#)

MessageID Property

Return the current message identifier.

Syntax

object.MessageID

Remarks

The read-only **MessageID** property returns the unique identifier for the current message.

Data Type

String

See Also

[HeaderField Property](#), [HeaderValue Property](#), [GetHeader Method](#)

MimeVersion Property

Gets and sets the MIME version number for the current message.

Syntax

object.MimeVersion [= *version*]

Remarks

The **MimeVersion** property returns the version number for the current message. Setting this property causes the MIME-Version header value to be changed to the specified value. An empty string causes the MIME version number to be set to the default value of "1.0".

Data Type

String

See Also

[HeaderField Property](#), [HeaderValue Property](#), [GetHeader Method](#), [SetHeader Method](#)

Organization Property

Gets and sets the name of the organization that originated the message.

Syntax

object.**Organization** [= *value*]

Remarks

The **Organization** property returns the name of the organization that originated the current message. Setting this property updates the specified header value. Note that many mailers do not generate an Organization header field, in which case the property value will be an empty string.

Data Type

String

See Also

[HeaderField Property](#), [HeaderValue Property](#), [GetHeader Method](#), [SetHeader Method](#)

Part Property

Gets and sets the current message part.

Syntax

object.**Part** [= *index*]

Remarks

Multipart email messages are structured using the MIME (Multipurpose Internet Mail Extensions) standard, which allows a single email to contain multiple content types, such as plain text, HTML, and file attachments, within a single message body. These components are organized as discrete parts, each with its own headers and body, separated by unique MIME boundaries. In a typical **multipart/alternative** message, part 0 often contains the message preamble (e.g.: "This is a multipart message in MIME format"), part 1 may contain the plain text version of the message, and part 2 may contain the HTML version. However, multipart messages are not required to include both plain text and HTML content. A message may only include an HTML part and one or more attachments, or any other combination of content types. The structure and ordering of parts depends entirely on how the original sender or mail client composed the message.

To simplify navigating these multipart structures, the **Part** property enables you to iterate through the individual parts of a message. The message parts are zero-based, with index 0 always referring to the top-level message headers and preamble. By changing the value of this property, you can change the currently selected message part, enabling methods like **GetHeader** to operate on that specific message part.

The internal MIME parser flattens multipart messages, meaning that if a message contains nested multipart sections (such as a multipart/mixed part containing a multipart/alternative part), all leaf parts are presented in a linear sequence. This simplifies access and avoids the complexity of recursive traversal. You can determine the total number of parts using the **PartCount** property and then iterate from part 0 to part N-1 to examine or extract each segment in order. This approach provides both fine-grained access to MIME message parts and an intuitive model for parsing even complex message structures.

For example, messages with file attachments typically consist of a message part which describes the contents of the attachment, followed by the attachment itself. For a message with one attached file, there would be a total of three parts. Part 0 would refer to the main message part, which contains the headers such as From, To, Subject, Date and so on. For multipart messages, part 0 typically does not have a message body, since any text is usually created as a separate part (for those messages that do not contain multiple parts, the part 0 body contains the text message). Part 1 would contain the text describing the attachment, and part 2 would contain the attachment itself. If the attached file is binary, then the transfer encoding type would usually be base64.

Data Type

Integer (Int32)

See Also

[ContentType Property](#), [ContentLength Property](#), [Encoding Property](#), [PartCount Property](#)

PartCount Property

Return the number of parts in the current message.

Syntax

object.**PartCount**

Remarks

The **PartCount** property returns the number of parts in the current message. All messages have at least one part, referenced as part 0. Multipart messages will consist of additional parts which may be accessed by setting the **Part** property.

Data Type

Integer (Int32)

See Also

[Part Property](#), [AttachFile Method](#), [Export Method](#), [ExtractFile Method](#)

Priority Property

Gets and sets the current message priority.

Syntax

object.Priority [= *value*]

Remarks

The **Priority** property returns the current priority for the message. Setting this property value causes the X-Priority header to be updated with the specified value.

There is no standard for specifying message priority. The convention is to use a number from 1-5, with 1 indicating the highest priority, 3 as normal priority and 5 as the lowest priority. Some mailers follow the number with a space and then text that describes the priority level.

Data Type

String

See Also

[HeaderField Property](#), [HeaderValue Property](#), [GetHeader Method](#), [SetHeader Method](#)

Recipient Property

Returns the address of a message recipient.

Syntax

object.Recipient(Index)

Remarks

The **Recipient** property array is used to enumerate the recipient addresses that have been specified in the current message. This includes all of the addresses listed in the To, Cc and Bcc header fields. Only the address itself will be returned, not any comments or extraneous text such as the full name of the recipient. This property array is zero based, meaning that the first index value is zero. The total number of recipients specified in the message can be determined by checking the value of the **Recipients** property.

Data Type

String

Example

The following example demonstrates how to use the **Recipient** property array and the **Recipients** property:

```
' Create a comma separated list of all of the recipient email  
' addresses currently specified in the message  
Dim strRecipients As String  
  
For nIndex = 0 To MailMessage1.Recipients - 1  
    If Len(strRecipients) > 0 Then strRecipients = strRecipients & ", "  
    strRecipients = strRecipients & MailMessage1.Recipient(nIndex)  
Next
```

See Also

[Bcc Property](#), [Cc Property](#), [Recipients Property](#), [To Property](#), [ParseAddress Method](#)

Recipients Property

Returns the number of recipients specified in the current message.

Syntax

object.Recipients

Remarks

The **Recipients** property returns the number of recipient addresses that have been specified in the current message. This includes all of the addresses listed in the To, Cc and Bcc header fields. This property can be used in conjunction with the **Recipient** property array to enumerate all of the recipient addresses in the message.

The **AllRecipients** property will return a comma-separated list of all message recipients.

Data Type

Integer (Int32)

Example

The following example demonstrates how to use the **Recipient** property array and the **Recipients** property:

```
' Create a comma separated list of all of the recipient email  
' addresses currently specified in the message  
Dim strRecipients As String  
  
For nIndex = 0 To MailMessage1.Recipients - 1  
    If Len(strRecipients) > 0 Then strRecipients = strRecipients & ", "  
    strRecipients = strRecipients & MailMessage1.Recipient(nIndex)  
Next
```

See Also

[AllRecipients Property](#), [Bcc Property](#), [Cc Property](#), [Recipient Property](#), [To Property](#)

ReplyTo Property

Gets and sets the address of the user who should receive replies to this message.

Syntax

object.ReplyTo [= *address*]

Remarks

The **ReplyTo** property returns the address of the user who should receive replies to the current message. Setting this property updates the Reply-To header with the specified value.

Data Type

String

See Also

[Bcc Property](#), [Cc Property](#), [From Property](#), [Sender Property](#), [To Property](#)

SelLength Property

Gets and sets the current message body text selection length.

Syntax

object.SelLength [= *length*]

Remarks

The **SelLength** property is used to set the length of the text selection in the current message body. When used in conjunction with the **SelStart** property, it can be used to refer to part of a message body.

Data Type

Integer (Int32)

See Also

[SelStart Property](#), [SelText Property](#), [Text Property](#)

SelStart Property

Gets and sets the starting position of the current message body text selection.

Syntax

object.SelStart [= *offset*]

Remarks

The **SelStart** property specifies a byte offset which is the starting position in the current message body. This property can be used in conjunction with the **SelLength** property to refer to part of a message body.

Data Type

Integer (Int32)

See Also

[SelLength Property](#), [SelText Property](#), [Text Property](#)

SelText Property

Gets and sets the selected message body text.

Syntax

object.SelText [= *message*]

Remarks

The **SelText** property returns the selected message body text as specified by the **SelStart** and **SelLength** properties. Setting this property replaces text in the message body starting at the byte offset specified by the **SelStart** property.

Data Type

String

See Also

[SelLength Property](#), [SelStart Property](#), [Text Property](#)

Sender Property

Gets and sets the address of the user who originated the message.

Syntax

object.Sender [= *address*]

Remarks

The **Sender** property returns the address of the user who originated the message. Setting this property updates the X-Sender header with the specified value.

Data Type

String

See Also

[Bcc Property](#), [Cc Property](#), [From Property](#), [ReplyTo Property](#), [To Property](#)

StoreCount Property

Returns the number of messages in the current storage file, not including deleted messages.

Syntax

object.StoreCount

Remarks

The **StoreCount** property returns the number of messages in the message store. It is important to note that does not count those messages which have been marked for deletion. This means that the value returned by this function will decrease as messages are deleted. To determine the total number of messages, including deleted messages, use the **StoreSize** property.

Data Type

Integer (Int32)

See Also

[StoreFile Property](#), [StoreIndex Property](#), [StoreSize Property](#), [DeleteMessage Method](#), [FindMessage Method](#), [OpenStore Method](#), [PurgeStore Method](#)

StoreFile Property

Gets and sets the name of the file used to store messages.

Syntax

object.StoreFile [= *filename*]

Remarks

The **StoreFile** property returns the name of the current storage file. Setting this property changes the default filename that is used when opening a new storage file. Note that this property value cannot be changed while a storage file is open; attempting to do so will result in an exception being thrown.

Data Type

String

See Also

[StoreCount Property](#), [StoreIndex Property](#), [OpenStore Method](#)

StoreIndex Property

Gets and sets the current message index for the current storage file.

Syntax

object.StoreIndex [= *value*]

Remarks

The **StoreIndex** property returns the current message index for the message store. Setting this property changes the current message index. When no storage file has been opened, this property will return a value of zero. After a storage file has been opened, it is changed to a value of one, the first message in the message store. The maximum value for this property is the number of messages in the store, as returned by the **StoreSize** property. Attempting to set this property to a value less than one or greater than the number of messages in the store will result in an exception being thrown.

This property value is updated whenever the **ReadStore** or **ReplaceMessage** methods are used. When the **WriteStore** method is used to store the current message in the message store, this property will be updated to reflect the message index of the newly added message.

Data Type

Integer (Int32)

See Also

[StoreCount Property](#), [StoreFile Property](#), [StoreSize Property](#), [FindMessage Method](#), [ReadStore Method](#), [WriteStore Method](#)

StoreSize Property

Returns the total number of messages in the current storage file, including deleted messages.

Syntax

object.StoreSize

Remarks

The **StoreSize** property returns the total number of messages in the message store, including those messages that have been deleted. Because the **StoreCount** property value will decrease as messages are deleted, it is recommended that you use this property value when iterating through all of the messages in the message store.

Data Type

Integer (Int32)

See Also

[StoreCount Property](#), [StoreFile Property](#), [StoreIndex Property](#), [DeleteMessage Method](#), [FindMessage Method](#), [OpenStore Method](#), [PurgeStore Method](#)

Subject Property

Gets and sets the subject of the current message.

Syntax

object.Subject [= *value*]

Remarks

The **Subject** property returns the subject of the current message. Setting this property updates the Subject header with the specified value. Note that not all messages have subjects, in which case this property will be set to an empty string.

Data Type

String

See Also

[HeaderField Property](#), [HeaderValue Property](#), [GetHeader Method](#), [SetHeader Method](#)

Text Property

Gets and sets the body of the current message part.

Syntax

object.Text [= *value*]

Remarks

The **Text** property returns the body of the current message part. Setting this property replaces the body of the current message part with the new text.

Data Type

String

See Also

[SelLength Property](#), [SelStart Property](#), [SelText Property](#)

TextLength Property

Returns the number of characters in the current message part after decoding.

Syntax

object.TextLength

Remarks

The **TextLength** property returns the actual length of the message text in the current message part. This value may be different than what is returned by the **ContentLength** property, which returns the value of the content length in bytes, as specified in the message header. The **TextLength** property returns the number of characters (not bytes) in the message text after the contents have been decoded and converted to Unicode.

Data Type

Integer (Int32)

See Also

[ContentLength Property](#), [Text Property](#)

ThrowError Property

Enables or disables error handling by the application.

Syntax

object.ThrowError = { True | False }

Remarks

Error handling for methods can be performed using either return codes or exceptions, depending on the value of this property.

If the **ThrowError** property is set to False, methods will return a status value indicating success or failure. Applications should check the return value of each method and use the **LastError** and **LastErrorString** properties to determine the cause of any error.

If the **ThrowError** property is set to True, errors occurring within the control will be raised to the host application as ActiveX exceptions. In addition, the **OnError** event will fire. This allows applications to use language-specific exception handling mechanisms, such as Visual Basic error handling, instead of checking individual return values after each method call.

Even when the **ThrowError** property is set to True, the **LastError** and **LastErrorString** properties will still be updated with information about the most recent error.

If an error occurs while accessing a property value, an exception will be raised regardless of the value of the **ThrowError** property. However, the **OnError** event will not be fired for property access errors.

Data Type

Boolean

Example

The following example handles errors by checking the return code of a method:

```
MailMessage1.ThrowError = False
nError = MailMessage1.Import(strFileName)

If nError > 0 Then
    MsgBox MailMessage1.LastErrorString, vbExclamation
    Exit Sub
End If
```

The following example handles errors by throwing them to the container:

```
On Error Resume Next: Err.Clear

MailMessage1.ThrowError = True
MailMessage1.Import strFileName

If Err.Number <> 0
    MsgBox Err.Description, vbExclamation
    Exit Sub
End If
On Error GoTo 0
```

See Also

[LastError Property](#), [LastErrorString Property](#), [OnError Event](#)

TimeZone Property

Gets and sets the current timezone offset in seconds.

Syntax

object.TimeZone [= *value*]

Remarks

The **TimeZone** property returns the current offset from UTC in seconds. Setting the property changes the current timezone offset to the specified value. The value of this property is initially determined by the date and time settings on the local system.

The **TimeZone** property value is used in conjunction with the **Localize** property to control how message date and time localization is handled.

Data Type

Integer (Int32)

Example

The following code enables localization and changes the current timezone to Eastern Standard, which is five hours (18,000 seconds) west of UTC:

```
MailMessage1.Localize = True  
MailMessage1.TimeZone = (5 * 60 * 60)
```

See Also

[Localize Property](#)

To Property

Gets and sets the address of the message recipient.

Syntax

object.**To** [= *addresses*]

Remarks

The **To** property returns the address of the message recipient. Setting this property causes the To header to be updated with the specified value. Multiple addresses can be specified by separating them with commas.

Data Type

String

See Also

[Bcc Property](#), [Cc Property](#), [From Property](#), [ReplyTo Property](#), [Sender Property](#)

Version Property

Return the current version of the control.

Syntax

object.Version

Remarks

The **Version** property returns the current version of the object. This can be used by an application for validation purposes. The version returned is composed of four numbers, separated by periods. The first number is the major version number, the second number is the minor version number, the third is the build number and the fourth is the revision number.

Data Type

String

Mail Message Control Methods

Method	Description
Append	Append text to the body of the current message part
AttachData	Attach the contents of a buffer to the current message
AttachFile	Attach the specified file to the current message
AttachImage	Attach an inline image to the current message
Clear	Clear the header and body of the current message
Close	Close the current message
CloseStore	Close the current message storage file
ComposeMessage	Compose a new mail message
CreatePart	Create a new message part in a multipart message
DecodeText	Decode a previously encoded string
DeleteHeader	Delete a header field from the current message part
DeleteMessage	Remove the specified message from the current message store
DeletePart	Delete the specified message part in the current message
EncodeText	Encode a string using base64 or quoted-printable encoding
Export	Export the current message to a file on the local system
ExtractAllFiles	Extract all file attachments from the current message
ExtractFile	Extract an attachment from the message and store it in a file
FindAttachment	Search the current message for a file attachment with the specified file name
FindMessage	Search for a message in the current message store
GetFirstHeader	Return the first header in the current message part
GetHeader	Return the value for the specified header in the current message part
GetNextHeader	Return the next header in the current message part
Import	Replace the current message with the contents of a file
Initialize	Initialize the control and validate the runtime license
NormalizeText	Normalize Unicode text, replacing confusable homoglyphs and symbols
Open	Open the specified text file and parse the contents
OpenStore	Open the specified message storage file
ParseAddress	Parse an Internet email address
Parse	Parse the specified string, adding the contents to the current message
PurgeStore	Purge all deleted messages from the current message store
ReadStore	Retrieve a message from the message store, replacing the current message

ReplaceMessage	Replace the specified message in the current message store
Reset	Reset the internal state of the control
SetHeader	Set the value for the specified header in the current message part
Uninitialize	Uninitialize the control and reset it to its default state
WriteStore	Store the current message in the message store

Append Method

Append text to the body of the current message part.

Syntax

object.Append(*MessageText*)

Parameters

MessageText

A string which specifies the message text to be appended to the current message part.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

If the current message is not a multipart message, it is marked as multipart and the attached file is appended to the message. If the message is already a multipart message, an additional part is created and the attachment is added to the message.

To attach data that is stored in a string or byte array rather than a file, use the **AttachData** method.

See Also

[Text Property](#), [Parse Method](#)

AttachData Method

Attach the contents of a buffer to the current message.

Syntax

object.AttachData(Buffer, [Length], [ContentName], [ContentType], [Options])

Parameters

Buffer

A string or byte array which specifies the data to be attached to the message. If an empty string is passed as the argument, no data is attached, but an additional empty message part will be created.

Length

An integer value which specifies the number of bytes of data in the buffer. If this value is omitted, the entire length of the string or size of the byte array is used.

ContentName

An optional string argument which specifies a name for the data being attached to the message. This typically is used as a file name by the mail client to store the data in. If this parameter is omitted or passed as an empty string then no name is defined and the data is attached as inline content. Note that if a file name is specified with a path, only the base name will be used.

ContentType

An optional string argument which specifies the type of data being attached. The value must be a valid MIME content type. If this parameter is omitted or passed as an empty string, then the buffer will be examined to determine what kind of data it contains. If there is only text characters, then the content type will be specified as "text/plain". If the buffer contains binary data, then the content type will be specified as "application/octet-stream", which is appropriate for any type of data.

Options

An optional integer value which specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
mimeAttachDefault	The data encoding is based on the content type. Text data is not encoded, and binary data is encoded using the standard base64 encoding algorithm. If this argument is omitted, this is the default value used.
mimeAttachBase64	The data is always encoded using the standard base64 algorithm, even if the buffer only contains printable text characters.
mimeAttachUcode	The data is always encoded using the uuencode algorithm, even if the buffer only contains printable text characters.
mimeAttachQuoted	The data is always encoded using the quoted-printable algorithm. This encoding should only be used if the data contains 8-bit text characters.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **AttachData** method allows an application to attach data to the message as either a file attachment or as inline content. The recipient of the message will see the attached data in the same way that they would see a file attached to the message using the **AttachFile** function.

If the specified message is not a multipart message, it is marked as multipart and the attached file is appended to the message. If the message is already a multipart message, an additional part is created and the attachment is added to the message.

Example

The following example demonstrates how to use the **AttachData** method in Visual Basic:

```
Dim hFile As Integer
Dim lpBuffer() As Byte
Dim cbBuffer As Long

' Open a file for binary access and read it into a
' byte array that will be attached to the message

hFile = FreeFile()
Open strDataFile For Binary As hFile
cbBuffer = LOF(hFile)
ReDim lpBuffer(cbBuffer)
Get hFile, , lpBuffer
Close hFile

' Compose a new message and then attach the contents
' of the buffer

MailMessage1.Compose strFrom, _
                    strTo, _
                    strCc, _
                    strSubject, _
                    strMessage

MailMessage1.AttachData lpBuffer, cbBuffer, strDataFile
```

See Also

[Attachment Property](#), [AttachFile Method](#), [ExtractFile Method](#)

AttachFile Method

Attach the specified file to the current message.

Syntax

object.AttachFile(FileName, [Options])

Parameters

FileName

A string which specifies the name of the file to be attached to the message. If the file is empty or does not exist, an error will be returned by the control.

Options

An optional integer value which specifies how the file will be attached to the message. If this argument is omitted and the file is a text file, it will not be encoded; if the file is a binary file, it will be base64 encoded. To override the default encoding used, specify one of the following options:

Value	Description
mimeAttachDefault	The file attachment encoding is based on the file content type. Text files are not encoded, and binary files are encoded using the standard base64 encoding algorithm. This is the default option for file attachments.
mimeAttachBase64	The file attachment is always encoded using the standard base64 algorithm, even if the attached file is a plain text file.
mimeAttachUucode	The file attachment is always encoded using the uuencode algorithm, even if the attached file is a plain text file.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **AttachFile** method attaches the specified file to the current message. If the message already contains one or more file attachments, then it is added to the end of the message. If the message does not contain any attached files, then it is converted to a multipart message and the file is appended to the message.

The **AttachImage** method can be used to attach an inline image to the message.

See Also

[Boundary Property](#), [ContentType Property](#), [AttachImage Method](#), [ExtractFile Method](#)

AttachImage Method

Attach an inline image to the current message.

Syntax

object.AttachImage(FileName, [ContentId])

Parameters

FileName

A string which specifies the name of the image file to be attached to the message. If the file is empty or does not exist, an error will be returned by the control.

ContentId

An optional string which specifies the content ID that is associated with the inline image. If this parameter is omitted or is an empty string, a random content ID string will be automatically generated.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **AttachImage** method attaches an inline image to the current message. Unlike a normal file attachment, this method is designed to be used with HTML formatted email messages that display images attached to the message. If the message already contains one or more images or file attachments, then it is added to the end of the message. If the message does not contain any attachments, then it is converted to a multipart message and the image is appended to the message.

The **AttachFile** method can be used to add standard file attachments to the message.

See Also

[Boundary Property](#), [ContentType Property](#), [AttachFile Method](#), [ExtractFile Method](#)

Clear Method

Clear the header and body of the current message.

Syntax

object.Clear

Parameters

None.

Return Value

A value of zero is returned if the action was successful. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **Clear** method clears the current message, releasing the memory allocated for the message and any attachments.

See Also

[SelLength Property](#), [SelStart Property](#), [SelText Property](#), [Text Property](#)

Close Method

Close the current message.

Syntax

object.Close

Parameters

None.

Return Value

A value of zero is returned if the action was successful. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **Close** method releases the memory allocated by the control when the message was opened or when a new message was composed. If this method is not explicitly called, the control will automatically close the current message when a new message is opened or when the control unloaded.

See Also

[Clear Method](#), [Compose Method](#), [Import Method](#), [Export Method](#), [Open Method](#)

CloseStore Method

Close the current message storage file.

Syntax

object.CloseStore

Parameters

None.

Return Value

A value of zero is returned if the action was successful. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **CloseStore** method closes the storage file that was previously opened, releasing all of the memory allocated for the message store and purging all deleted messages. This method must be called when the application has finished accessing the messages in the message store.

When the control instance is released by its container, the storage file will automatically be closed. To prevent deleted messages from being removed from the message store, use the **Reset** method.

See Also

[StoreFile Property](#), [OpenStore Method](#), [PurgeStore Method](#), [ReadStore Method](#), [WriteStore Method](#)

Compose Method

Compose a new mail message.

Syntax

```
object.Compose( From, To, [Cc], [Bcc], [Subject], [MessageText], [MessageHTML], [CharacterSet], [EncodingType] )
```

Parameters

From

A string argument which specifies the sender's email address. Only a single address should be specified. After the message has been composed, the **From** property will be updated with this value.

To

A string argument which specifies one or more recipient email addresses. Multiple email addresses may be specified by separating them with commas. After the message has been composed, the **To** property will be updated with this value.

Cc

An optional string which specifies one or more additional recipient addresses that will receive a copy of the message. If this argument is not specified, then no Cc header field will be created for this message. After the message has been composed, the **Cc** property will be updated with this value.

Bcc

An optional string which specifies one or more additional recipient addresses that will receive a "blind" copy of the message. If this argument is not specified, then no Bcc header field will be created for this message. After the message has been composed, the **Bcc** property will be updated with this value. Note that the Bcc header field is not normally included in the header when the message is exported.

Subject

An optional string argument which specifies the subject for the message. If the argument is not specified, then no Subject header field will be created for this message. After the message has been composed, the **Subject** property will be updated with this value.

MessageText

An optional string argument which specifies the body of the message. Each line of text contained in the string should be terminated with a carriage-return/linefeed (CRLF) pair, which is recognized as the end-of-line. If the argument is not specified, then the message will have an empty body unless the **MessageHTML** argument has been specified.

MessageHTML

An optional argument which specifies an alternate HTML formatted message. If the **MessageText** argument has been specified, then a multipart message will be created with both plain text and HTML text as the alternative. This allows mail clients to select which message body they wish to display. If the **MessageText** argument is not specified or is an empty string, then the message will only contain HTML. Although this is supported, it is not recommended because older mail clients may be unable to display the message correctly.

CharacterSet

An optional integer value which specifies the [character set](#) for the message text. If this parameter is

omitted, the default is for the message to be composed using the standard UTF-8 character set.

EncodingType

An optional integer value which specifies the content encoding to use for the message text. The default is for the control to use 8-bit encoding. One of the following values may be used:

Value	Description
mimeEncoding7Bit	Each character is encoded in one or more bytes, with each byte being 8 bits long, with the first bit cleared. This encoding is most commonly used with plain text using the US-ASCII character set, where each character is represented by a single byte in the range of 20h to 7Eh.
mimeEncoding8Bit	Each character is encoded in one or more bytes, with each byte being 8 bits long and all bits are used. 8-bit encoding is used with UTF-8 and other multi-byte character sets,
mimeEncodingQuoted	Quoted-printable encoding is designed for textual messages where most of the characters are represented by the ASCII character set and is generally human-readable. Non-printable characters or 8-bit characters with the high bit set are encoded as hexadecimal values and represented as 7-bit text. Quoted-printable encoding is typically used for messages which use character sets such as ISO-8859-1, as well as those which use HTML.
mimeEncodingBase64	Base64 encoding converts binary or text data to ASCII by translating it so each base64 digit represents 6 bits of data. This encoding method is commonly used with messages that contain binary data (such as binary file attachments), or when text uses extended characters that cannot be represented by 7-bit ASCII. It is recommended that you use base64 encoding with Unicode text.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

email addresses may be specified as simple addresses, or as commented addresses that include the sender's name or other information. For example, any one of these address formats are acceptable:

```
user@domain.tld
User Name <user@domain.tld>
user@domain.tld (User Name)
```

To specify multiple addresses, you should separate each address by a comma or semi-colon. Note that the **From** parameter cannot specify multiple addresses, however it is permitted with the **To**, **Cc** and **Bcc** parameters.

To send a message that contains HTML, it is recommended that you provide both a plain text version of the message body and an HTML formatted version. While it is permitted to send a message that only contains HTML, some older mail clients may not be capable of displaying the message correctly. In some cases, anti-spam software will increase the spam score of messages that do not contain a

plain text message body. This can result in your message being rejected or quarantined by the mail server.

Example

```
nError = MailMessage1.Compose(editFrom.Text, _  
                                editTo.Text, _  
                                editCc.Text, _  
                                editBcc.Text, _  
                                editSubject.Text, _  
                                editMessage.Text)  
  
If nError > 0 Then  
    MessageBox MailMessage1.LastErrorString, vbExclamation  
Exit Sub  
End If
```

See Also

CreatePart Method

Create a new message part in a multipart message.

Syntax

```
object.CreatePart( [MessageText], [CharacterSet], [EncodingType] )
```

Parameters

MessageText

An optional string argument which specifies the body of the new message part. Each line of text contained in the string should be terminated with a carriage-return/linefeed (CRLF) pair, which is recognized as the end-of-line. If the argument is not specified, then the message part will have an empty body.

CharacterSet

An optional integer value which specifies the [character set](#) for the message part. If this parameter is omitted, the default is for the message to be composed using the standard UTF-8 character set.

EncodingType

An optional integer value which specifies the content encoding to use for the message part. The default is for the control to use 7-bit encoding. If an 8-bit character set is specified for the **CharacterSet** argument, the default encoding type will be set to quoted-printable. One of the following values may be used:

Value	Description
mimeEncoding7Bit	Each character is encoded in one or more bytes, with each byte being 8 bits long, with the first bit cleared. This encoding is most commonly used with plain text using the US-ASCII character set, where each character is represented by a single byte in the range of 20h to 7Eh.
mimeEncoding8Bit	Each character is encoded in one or more bytes, with each byte being 8 bits long and all bits are used. 8-bit encoding may be used with UTF-8 and other multi-byte character sets.
mimeEncodingQuoted	Quoted-printable encoding is designed for textual messages where most of the characters are represented by the ASCII character set and is generally human-readable. Non-printable characters or 8-bit characters with the high bit set are encoded as hexadecimal values and represented as 7-bit text. Quoted-printable encoding is typically used for messages which use character sets such as ISO-8859-1, as well as those which use HTML.
mimeEncodingBase64	Base64 encoding converts binary or text data to ASCII by translating it so each base64 digit represents 6 bits of data. This encoding method is commonly used with messages that contain binary data (such as binary file attachments), or when text uses extended characters that cannot be represented by 7-bit ASCII. It is recommended that you use base64 encoding with Unicode text.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **CreatePart** method creates a new message part. If the current message is a simple RFC822 formatted message, then this method converts it to a MIME multipart message. The current message part will be set to the new part that was just created.

See Also

[Bcc Property](#), [Cc Property](#), [Encoding Property](#), [From Property](#), [Subject Property](#), [Text Property](#), [To Property](#)

DecodeText Method

Decode a string which was previously encoded using base64 or quoted-printable encoding.

Syntax

```
object.DecodeText( EncodedText, MessageText, [CharacterSet], [EncodingType] )
```

Parameters

EncodedText

A string which contains the encoded text which should be decoded.

MessageText

A string variable passed by reference which will contain the decoded text when the method returns.

CharacterSet

An optional integer value which specifies the [character set](#) to use when decoding the encoded text. If this value does not match the character set used when the text was originally encoded, the resulting output text may be invalid. If no character set is specified, this method will default to using UTF-8.

EncodingType

An optional integer value which specifies the content encoding to use when decoding the text. It may be one of the following values:

Value	Description
mimeEncodingQuoted	Quoted-printable encoding is designed for textual messages where most of the characters are represented by the ASCII character set and is generally human-readable. Non-printable characters or 8-bit characters with the high bit set are encoded as hexadecimal values and represented as 7-bit text. Quoted-printable encoding is typically used for messages which use character sets such as ISO-8859-1, as well as those which use HTML.
mimeEncodingBase64	Base64 encoding converts binary or text data to ASCII by translating it so each base64 digit represents 6 bits of data. This encoding method is commonly used with messages that contain binary data (such as binary file attachments), or when text uses extended characters that cannot be represented by 7-bit ASCII. It is recommended that you use base64 encoding with Unicode text. This is the default encoding type used by this method.

Return Value

The method returns the number of characters of decoded text. A return value of zero indicates no text has been decoded. If the method fails, it will return -1 and the **LastError** property can be used to determine the cause of the failure. In most cases where the method fails, it is because an invalid character set or encoding type has been specified.

Remarks

This method provides a means to decode text that was previously encoded using either base64 or

quoted-printable encoding. In most cases, it is not necessary to use this method because the message parser will detect which character set and encoding was used, then automatically decode the message text if necessary.

The value of the **CharacterSet** parameter does not affect the resulting output text, it is only used when decoding the input text. The previous contents of the **MessageText** string will be replaced by the decoded text, and the output string will always be Unicode.

If the **CharacterSet** parameter is specified as **mimeCharsetUTF16**, the encoding type must be **mimeEncodingBase64**. Other encoding methods are not supported for Unicode strings and will cause the method to fail. In most cases, it is preferable to always use **mimeEncodingBase64** as the encoding method, with quoted-printable encoding only used for legacy support. If an unsupported encoding type is specified, this method will return -1 and the output text string will be empty. This method cannot be used to decode uuencoded text.

If you are developing your application using Visual Basic 6.0, the IDE does not provide complete support for Unicode. The decoded text may appear to be corrupted when examining it in the debugger. This is because the IDE will attempt to convert the string to ANSI using the system default code page. To display Unicode text correctly, you must use controls which are Unicode aware, such as the Microsoft InkEdit control.

See Also

[Encoding Property](#), [Text Property](#), [Compose Method](#), [CreatePart Method](#), [EncodeText Method](#)

DeleteHeader Method

Delete a header field from the current message part.

Syntax

object.DeleteHeader(HeaderField)

Parameters

HeaderField

A string which specifies the header field to delete from the current message part.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **DeleteHeader** method deletes the specified header field value from the current message part.

See Also

[HeaderField Property](#), [HeaderValue Property](#), [Part Property](#), [PartCount Property](#), [GetHeader Method](#), [SetHeader Method](#)

DeleteMessage Method

Remove the specified message from the current message store.

Syntax

object.DeleteMessage([MessageIndex])

Parameters

MessageIndex

An integer value which specifies the message that is to be removed from the message store. If this parameter is omitted, the current message as specified by the value of the **StoreIndex** property will be used.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **DeleteMessage** method marks the specified message for deletion from the storage file. When the message store is closed or purged, the message is removed from the file. Once a message has been marked for deletion, it may no longer be referenced by the application. For example, you cannot access the contents of a message that has been deleted.

The message store must be opened with write access. This method will fail if you attempt to delete a message from a storage file that has been opened for read-only access. If the application needs to delete messages in the message store, it is recommended that the file be opened for exclusive access using the **mimeStoreLock** option when calling the **OpenStore** method.

See Also

[StoreCount Property](#), [StoreIndex Property](#), [PurgeStore Method](#), [ReadStore Method](#), [ReplaceMessage Method](#), [WriteStore Method](#)

DeletePart Method

Delete the specified message part in the current message.

Syntax

object.DeletePart([*MessagePart*])

Parameters

MessagePart

An optional integer value which specifies the message part to remove from a multipart message.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **DeletePart** method deletes the specified message part in the current message. If the optional message part is not specified, then the current message part is deleted. This method cannot be used to delete the main body of the message. Use the **Clear** method to clear the contents of the complete message.

See Also

[AttachFile Method](#), [Clear Method](#), [CreatePart Method](#)

EncodeText Method

Encodes a string using base64 or quoted-printable encoding.

Syntax

`object.EncodeText( MessageText, EncodedText, [CharacterSet], [EncodingType] )`

Parameters

MessageText

A string that contains the text which will be encoded.

EncodedText

A string variable passed by reference which will contain the encoded text when the method returns.

CharacterSet

An optional integer value which specifies the [character set](#) to use when encoding the text. If no character set is specified, this method will default to using UTF-8.

EncodingType

An optional integer value which specifies the content encoding type. It may be one of the following values:

Value	Description
mimeEncodingQuoted	Quoted-printable encoding is designed for textual messages where most of the characters are represented by the ASCII character set and is generally human-readable. Non-printable characters or 8-bit characters with the high bit set are encoded as hexadecimal values and represented as 7-bit text. Quoted-printable encoding is typically used for messages which use character sets such as ISO-8859-1, as well as those which use HTML.
mimeEncodingBase64	Base64 encoding converts binary or text data to ASCII by translating it so each base64 digit represents 6 bits of data. This encoding method is commonly used with messages that contain binary data (such as binary file attachments), or when text uses extended characters that cannot be represented by 7-bit ASCII. It is recommended that you use base64 encoding with Unicode text. This is the default encoding type used by this method.

Return Value

The method returns the number of characters of encoded text. A return value of zero indicates no text has been encoded. If the method fails, it will return -1 and the **LastError** property can be used to determine the cause of the failure. In most cases where the method fails, it is because an invalid character set or encoding type has been specified.

Remarks

This method provides a means to encode text using either base64 or quoted-printable encoding. It is not necessary to use this method to encode text when assigning a value to the **Text** property. The control will automatically encode message text which contains non-ASCII characters using the

character set specified when the message is created.

If the **CharacterSet** parameter is specified, the method will convert the message text using the ANSI code page associated with the character set, and then the text will be encoded. If the parameter is omitted, the message text will be converted to UTF-8 and then encoded.

If the **mimeCharsetUTF16** character set is specified, you must also specify **mimeEncodingBase64** as the encoding method. Other encoding methods are not supported and this will cause the method to fail. It is not recommended you encode text as UTF-16 unless there is a specific requirement to use that character set.

It is recommended that you use the **mimeCharsetUTF8** character set whenever possible. It is capable of encoding all Unicode code points, and is a standard for virtually all modern Internet applications. In most cases, it is preferable to use **mimeEncodingBase64** as the encoding method, with quoted-printable encoding only used for legacy support.

If you are developing your application using Visual Basic 6.0, the IDE does not provide complete support for Unicode. The decoded text may appear to be corrupted when examining it in the debugger. This is because the IDE will attempt to convert the string to ANSI using the system default code page. To display Unicode text correctly, you must use controls which are Unicode aware, such as the Microsoft InkEdit control.

[Encoding Property](#), [Text Property](#), [Compose Method](#), [CreatePart Method](#), [DecodeText Method](#)

Export Method

Export the current message to a file on the local system.

Syntax

`object.Export( FileName, [Options] )`

Parameters

FileName

A string which specifies the name of the file that will contain the message. If the file does not exist, it will be created. If it does exist, it will be overwritten with the contents of the message.

Options

An optional integer value which specifies one or more options. If this argument is omitted, the **Options** property value will be used as the default. The following values may be combined using a bitwise Or operator:

Value	Description
mimeOptionDefault	The default export options. The headers for the message are written out in a specific consistent order, with custom headers written to the end of the header block regardless of the order in which they were set or imported from another message. If the message contains Bcc, Received, Return-Path, Status or X400-Received header fields, they will not be exported.
mimeOptionAllHeaders	All headers, including the Bcc, Received, Return-Path, Status and X400-Received header fields will be exported. Normally these headers are not exported because they are only used by the mail transport system. This option can be useful when exporting a message to be stored on the local system, but should not be used when exporting a message to be delivered to another user.
mimeOptionKeepOrder	The original order in which the message header fields were set or imported are preserved when the message is exported.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

See Also

[Import Method](#)

ExtractAllFiles Method

Extract all file attachments from the current message, storing them in the specified directory.

Syntax

object.ExtractAllFiles([*Directory*])

Parameters

Directory

An optional string that specifies the name of the directory where the file attachments should be stored. If this parameter is omitted or points to an empty string, the attached files will be stored in the current working directory on the local system.

Return Value

If the method succeeds, the return value is the number of file attachments which were extracted from the current message. If the message does not contain any file attachments, this method will return a value of zero. If the method fails, the return value is -1. To get extended error information, check the value of the **LastError** property.

Remarks

This method will extract all of the files that are attached to the current message and store them in the specified directory. The directory must exist and the current user must have the appropriate permissions to create files there. If a file with the same name as the attachment already exists, it will be overwritten with the contents of the attachment. If the file attachment was encoded using base64 or uuencode, this method will automatically decode the contents of the attachment.

To store a file attachment on the local system using a name that is different than the file name of the attachment, use the **ExtractFile** method.

See Also

[Attachment Property](#), [AttachData Method](#), [AttachFile Method](#), [ExtractFile Method](#)

ExtractFile Method

Extract the contents of a file attachment and store it on the local system.

Syntax

object.ExtractFile(*FileName*, [*MessagePart*])

Parameters

FileName

A string which specifies the name of the file that the attachment will be written to. If the file does not exist, it will be created. If the file exists, it will be overwritten.

MessagePart

An optional integer value that specifies the message part number that contains the file attachment. If this parameter is omitted, the method will extract the file attachment in the current message part.

Return Value

A value of zero is returned if the action was successful. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **ExtractFile** method writes the contents of a message part, typically a file attachment, to a file on the local system. This method will automatically decode any binary file attachments. To determine if the current message part contains a file attachment, check the value of the **Attachment** property.

See Also

[Attachment Property](#), [AttachData Method](#), [AttachFile Method](#), [ExtractAllFiles Method](#), [FindAttachment Method](#)

FindAttachment Method

Search the current message for a file attachment with the specified file name.

Syntax

object.FindAttachment(*FileName*)

Parameters

FileName

A string that specifies the name of the file attachment to search for. This parameter should only specify a base file name; it should not include a file path and cannot be an empty string.

Return Value

If the method succeeds, the return value is the message part number that contains the file attachment. If the message does not contain an attachment that matches the specified file name, the return value is -1. To get extended error information, check the value of the **LastError** property.

Remarks

The **FindAttachment** method will search the current message for an attachment that matches the specified file name. The search is not case-sensitive, however it must match the attachment file name completely. This method will not match partial file names or names that include wildcard characters.

Example

```
nMessagePart = MailMessage1.FindAttachment(strFileName)

If nMessagePart > -1 Then
    MailMessage1.ExtractFile(strFileName, nMessagePart)
End If
```

See Also

[Attachment Property](#), [AttachFile Method](#), [ExtractAllFiles Method](#), [ExtractFile Method](#)

FindMessage Method

Search for a message in the current message store.

Syntax

object.FindMessage(*HeaderField*, *HeaderValue*, [*MessageIndex*], [*Options*])

Parameters

HeaderField

A string which specifies the name of the header field that should be searched. The header field name is not case sensitive.

HeaderValue

A string which specifies the header value that should be searched for. The search options can be used to specify if the search is case-sensitive, and whether the search should return partial matches to the string.

MessageIndex

An optional integer value which specifies the message number that should be used when starting the search. If this parameter is omitted, the search will begin with the first message in the message store.

Options

An optional integer value which specifies how the search will be performed. If this parameter is omitted, the default search options will be used. One or more of the following values may be specified:

Value	Description
mimeSearchDefault	Perform a complete match against the specified header value. The comparison is not case-sensitive. It is the default search option used if this parameter is omitted.
mimeSearchCaseSensitive	The header value comparison will be case-sensitive. Note that this does not affect header field names. Matches for header names are always case-insensitive.
mimeSearchPartialMatch	Perform a partial match against the specified header value. It recommended that this option be used when searching for matches to email addresses.
mimeSearchDecodeHeaders	Decode any encoded message headers before comparing them to the specified value. This option can increase the amount of time required to search the message store and should only be used when necessary.

Return Value

If the method is successful, it returns the message number which specifies the message that matches the search criteria. If no matching message could be found, the method will return zero.

Remarks

The **FindMessage** method is used to search the message store for a message which matches a specific header field value. For example, it can be used to find every message which is addressed to a

specific recipient or has a subject which matches a particular string value.

See Also

[StoreCount Property](#), [StoreIndex Property](#), [CloseStore Method](#), [OpenStore Method](#), [ReadStore Method](#), [WriteStore Method](#)

GetFirstHeader Method

Return the first header in the current message part.

Syntax

object.GetFirstHeader(*HeaderField*, *HeaderValue*)

Parameters

HeaderField

A string which will contain the name of the first header field when the method returns. This parameter must be passed by reference.

HeaderValue

A string which will contain the value of the first header field when the method returns. This parameter must be passed by reference.

Return Value

A value of True is returned if the first header value was returned. If the current message part does not contain any header fields, this method will return False.

Example

The following example enumerates all of the headers in the main part of the current message and adds them to a listbox:

```
Dim strHeader As String, strValue As String
Dim bResult As boolean

bResult = MailMessage1.GetFirstHeader(strHeader, strValue)
Do While bResult
    List1.AddItem strHeader & ": " & strValue
    bResult = MailMessage1.GetNextHeader(strHeader, strValue)
Loop
```

See Also

[Part Property](#), [GetHeader Method](#), [GetNextHeader Method](#), [SetHeader Method](#)

GetHeader Method

Return the value for the specified header in the current message part.

Syntax

object.GetHeader(*HeaderField*, *HeaderValue*)

Parameters

HeaderField

A string variable which will specifies the name of the header field to return the value of. Header field names are not case sensitive.

HeaderValue

A string variable which will contain the value of the specified header field.

Return Value

A value of True is returned if the header value was returned. If the current message part does not contain the specified header field, this method will return False.

Parameters

The **GetHeader** method is used to retrieve the value for a specific header in the current message part. If there are multiple headers with the same name, the first value will be returned. To enumerate all of the headers in a message, including duplicate header fields, use the **GetFirstHeader** and **GetNextHeader** methods.

See Also

[AllHeaders Property](#), [Part Property](#), [GetFirstHeader Method](#), [GetNextHeader Method](#), [SetHeader Method](#)

GetNextHeader Method

Return the next header in the current message part.

Syntax

object.GetNextHeader(*HeaderField*, *HeaderValue*)

Parameters

HeaderField

A string which will contain the name of the next header field when the method returns. This parameter must be passed by reference.

HeaderValue

A string which will contain the value of the next header field when the method returns. This parameter must be passed by reference.

Return Value

A value of True is returned if the next header value was returned. If there are no more header fields in the current message part, this method will return False.

Example

The following example enumerates all of the headers in the main part of the current message and adds them to a listbox:

```
Dim strHeader As String, strValue As String
Dim bResult As boolean

bResult = MailMessage1.GetFirstHeader(strHeader, strValue)
Do While bResult
    List1.AddItem strHeader & ": " & strValue
    bResult = MailMessage1.GetNextHeader(strHeader, strValue)
Loop
```

See Also

[Part Property](#), [GetFirstHeader Method](#), [GetHeader Method](#), [SetHeader Method](#)

Import Method

Replace the current message with the contents of a file.

Syntax

object.Import(FileName)

Parameters

FileName

A string which specifies the name of the text file to import.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

See Also

[Append Method](#), [Export Method](#), [Parse Method](#)

Initialize Method

Initialize the control and validate the runtime license key.

Syntax

```
object.Initialize( [LicenseKey] )
```

Parameters

LicenseKey

An optional string value which specifies a runtime license key used to initialize the control. If the license key is omitted or passed as an empty string, a development license must be installed on the local system.

Return Value

A value of zero is returned if the control was initialized successfully. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

This method dynamically loads other system libraries and allocates thread local storage. In most cases, it is not necessary to call this method directly because it is automatically invoked when an instance of the control is created by the container. However, if the control is created dynamically using **CreateObject** or a similar method, this must be the first method that is called before you attempt to modify any property values or invoke other methods. Failure to initialize the control may result in subsequent errors and/or cause an exception to be raised.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the control will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the control was created.

If the control is being used within another DLL, it is important that you do not attempt to create an instance of the control or call the **Initialize** method from within the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is written in C++ and it is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for any static and global C++ objects and has the same restrictions.

Example

```
Set objMessage = CreateObject("SocketTools.MailMessage.12")

nError = objMessage.Initialize(strLicenseKey)
If nError > 0 Then
    MsgBox "Unable to initialize SocketTools component"
End
End If
```

See Also

[Uninitialize Method](#)

NormalizeText Method

Normalize Unicode text, replacing confusable homoglyphs and symbols.

Syntax

object.**NormalizeText**(MessageText)

Parameters

MessageText

A variant type which may specify either a string or byte array. If a string type is passed to this method, the text will be normalized. If a byte array is passed to this method, it will be processed as UTF-8 encoded characters, with the result returned as a string. No other data types are accepted by this method and an exception will be thrown if an invalid data type is provided as the input text.

Return Value

If the method is successful it returns a string which contains the normalized text. If the method fails, it will return an empty string. If the text appears to be intentionally malformed, this method will throw an exception which must be handled by the application.

Remarks

The **NormalizeText** method performs a multi-stage normalization and cleanup of Unicode text, intended to simplify and standardize input that may contain visually similar (confusable) characters, diacritical marks, or inconsistent whitespace. It applies NFKD (Compatibility Decomposition) normalization converting characters into their canonical forms and then replaces any confusable Unicode characters with their ASCII equivalents based on an internal mapping table. This method is similar to calling the **NormalizeString** function in the Windows API, however it performs additional checks and is more strict with how the input is validated.

If the message text is provided as a byte array, it is validated to ensure it contains only valid UTF-8 encoding. If the text contains invalid UTF-8 sequences, this method will fail. You should never pass in a localized byte array encoded using the system code page using the **StrConv** function. If the message text is provided as a string, it is validated to ensure it contains only well-formed UTF-16. If the text includes malformed Unicode, embedded nulls, or arbitrary binary data, the method will fail.

This method helps mitigate issues with characters that are visually indistinguishable from standard Latin letters, such as using the Cyrillic "a" (U+0430) instead of the Latin "a" (U+0061). It also removes symbols (such as emojis, flags and pictographs) which can confuse pattern matching and removes combining marks that can be used to visually modify characters or obscure text. Unicode whitespace is trimmed from both ends of the string, including zero-width and non-breaking spaces.

If you want a normalized version of the text in a message, you can use the **FilteredText** property. It performs many of the same normalizations that this method does, but allows for more flexibility through options which allow you to control how the message text is processed and filtered. It is particularly useful for filtering extraneous HTML from the message, enabling you to display a version of the message that is safer for the user (such as removing unsafe links from the message contents).

The **FilteredText** property is tolerant of malformed Unicode text in a message, while the **NormalizeText** method is designed be stricter with how it processes the text. If there are any malformed characters (such as unpaired surrogates, over-long or truncated UTF-8 characters, invalid continuation sequences or characters outside of valid Unicode code points), this method will fail and throw an exception which must be handled appropriately by your application. The intent is to enable

you to detect what may be intentionally malformed text in the contents of a message or a header value.

Note that standard Visual Basic controls such as **Label** and **TextBox** do not fully support displaying Unicode characters, especially those outside the Basic Multilingual Plane (such as emoji or mathematical symbols). These controls attempt to convert Unicode strings to ANSI using the system locale, which can result in garbled or missing characters. To correctly display full Unicode text, you must use controls that support Unicode natively, such as those in the Microsoft Forms 2.0 Object Library (FM20.DLL) with appropriate font settings, or render the text using Windows API functions.

Example

A string containing bold mathematical Unicode characters is normalized to produce a simplified, plain text version. If you wanted to display the obfuscated Unicode text in this example, you would need to use a Unicode-aware control such as the **TextBox** control in the Microsoft Forms 2.0 Object Library. You would also need to select a font which is capable of displaying Unicode math symbols, such as the **Cambria Math** font. The advantage of using the **NormalizeText** method is that it will convert this type of Unicode text to something which is displayable without requiring specific UI components and fonts.

```
Dim sUnicode As String
sUnicode = ChrW(&HD835) & ChrW(&HDC07) & ChrW(&HD835) & ChrW(&HDC1E) & ChrW(&HD835)
& ChrW(&HDC25) & _
    ChrW(&HD835) & ChrW(&HDC25) & ChrW(&HD835) & ChrW(&HDC28) & "!" '
"Hello!" in math bold

' Normalize a UTF-16 Unicode string, returning a plain text version
Dim sPlainText As String
sPlainText = MailMessage1.NormalizeText(sUnicode)
MsgBox sPlainText, vbInformation, "Normalized Text"
```

See Also

[Filter Property](#), [FilteredText Property](#), [Text Property](#), [TextLength Property](#)

Open Method

Open the specified text file and parse the contents.

Syntax

object.Open(FileName)

Parameters

FileName

A string which specifies the name of the file.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

This method opens the specified file, reads the contents into memory and then parses the message. The file must be a text file which uses the standard MIME message structure. It may contain multiple parts, including file attachments and alternative representations of the same message. This function cannot be used to open messages stored in a binary format.

The maximum size of an individual message is 2 GiB (approximately 2 billion characters). This limitation is implemented as a safety check to prevent opening very large files which are unlikely to contain a valid MIME formatted message. Most services impose much lower limits on the maximum size of an individual mail message.

Note: This method can only be used to open and parse messages structured according to the MIME (Multipurpose Internet Mail Extensions) standard, such as plain text **.eml** or **.txt** files. It cannot open messages stored in proprietary or binary formats used by certain email clients. For example, it does not support Microsoft Outlook message files such as **.msg** or mailbox files like **.pst** and **.ost**, nor does it support formats used by other clients such as Thunderbird's **.msf** (mail summary files) or the mbox family (**.mbx**, **.mbox**) when stored as binary containers. Attempting to open these file types will result in an error. If you need to work with messages exported from Outlook or other proprietary clients, first save or export them in the standard text format before using this method.

If another message was previously opened or created using the same instance of the control, the internal handle which references the previous message will be closed. If you wish to preserve any changes made to the current message, use the **Export** method prior to calling this method.

See Also

[Close Method](#), [Export Method](#), [Import Method](#)

OpenStore Method

Open the specified message storage file.

Syntax

object.OpenStore(*FileName*, [*OpenMode*])

Parameters

FileName

A string which specifies the name of the storage file.

OpenMode

An optional integer value which specifies how the storage file will be opened. If this parameter is omitted, the file will be opened for read-only access. One or more of the following values may be specified:

Value	Description
mimeStoreRead	The message store will be opened for read access. The contents of the message store can be accessed, but cannot be modified by the process unless it has also been opened for writing.
mimeStoreWrite	The message store will be opened for writing. This mode also implies read access and must be specified if the application needs to modify the contents of the message store.
mimeStoreCreate	The message store will be created if the storage file does not exist. If the file exists, it will be truncated. This mode implies read and write access.
mimeStoreLock	The message store will be opened so that it may only be accessed and modified by the current process.
mimeStoreCompress	The contents of the message store are compressed. This option is automatically enabled if a compressed message store is opened for reading or writing.
mimeStoreMailbox	The message store should use the UNIX mbox format when reading and storing messages. This option is provided for backwards compatibility and is not recommended for general use.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **OpenStore** method opens a message storage file which contains one or more messages. If the storage file is opened for read access, the application can search the message store and extract messages but it cannot add or delete messages. To add new messages or delete existing messages from the store, it must be opened with write access.

The message store is designed to be a simple, effective way to store multiple messages together in a single file. When the message store is opened, the contents are indexed in memory. Although there is no specific limit to the number of messages that can be stored, there must be sufficient memory

available to build an index of each message and its headers. If the application must store and manage a very large number of messages, it is recommended that you use a database rather than a flat-file message store.

Message Store Format

Each message is prefixed by a control sequence of five ASCII 01 characters followed by an ASCII 10 and ASCII 13 character. The messages themselves are stored unmodified in their original text format. The length of each message is calculated based on the location of the control sequence that delimits each message, and explicit message lengths are not stored in the file. This means that it is safe to manually change the message contents, as long as the message delimiters are preserved.

If the message store is compressed, the contents of the storage file are expanded when the file is opened and then re-compressed when the storage file is closed. Using the **mimeStoreCompress** option reduces the size of the storage file and prevents the contents of the message store from being read using a text file editor. However, enabling compression will increase the amount of memory allocated by the control and can increase the amount of time that it takes to open and close the storage file.

The control also has a backwards compatibility mode where it will recognize storage files that use the UNIX mbox format. While this format is supported for accessing existing files, it is not recommended that you use it when creating new message stores or adding messages to an existing store. There are a number of different variants on the mbox format that have been used by different Mail Transfer Agents (MTAs) on the UNIX platform. For example, the mboxrd variant looks identical to the mboxcl2 variant, and they are programmatically indistinguishable from one another, but they are not compatible. For this reason, the use of the mbox format is strongly discouraged.

ParseAddress Method

Parse an Internet email address.

Syntax

object.ParseAddress(*Address*)

Parameters

Address

A string which specifies the email address to be parsed.

Return Value

A string containing the parsed address is returned if method was successful, otherwise an empty string is returned.

Remarks

The **ParseAddress** method parses a string which contains an email address and returns only the address portion, excluding any comments. An address may contain comments enclosed in parenthesis, or may specify a name along with the address in which case the address is enclosed in angle brackets. For example, consider the following header field value:

"User Name" <user@domain.com> (This is a comment)

The **ParseAddress** method would return "user@domain.com" if passed the above string, removing the name and any comments. Note that the **ParseAddress** method will only parse a single address. If multiple addresses are specified, they must be comma delimited and split prior to calling this method.

Example

The following example parses all of the recipient email addresses in the current message, storing them in the *strAddresses* string array.

```
Dim strAddresses() As String, strAddress As String
Dim nIndex As Integer, nAddresses As Integer

nAddresses = 0
strAddresses = Split(MailMessage1.To & "," & MailMessage1.Cc, ",")

For nIndex = 0 To UBound(strAddresses)
    If Len(Trim(strAddresses(nIndex))) > 0 Then
        strAddress = MailMessage1.ParseAddress(strAddresses(nIndex))
        If Len(strAddress) > 0 Then
            strAddresses(nAddresses) = strAddress
            nAddresses = nAddresses + 1
        End If
    End If
Next
```

See Also

[Cc Property](#), [From Property](#), [To Property](#)

Parse Method

Parse the specified string, adding the contents to the current message.

Syntax

object.Parse(*MessageText*)

Parameters

MessageText

A string that contains the message text to be parsed.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **Parse** method parses a string which contains message data, adding it to the current message. This method is useful when the application needs to parse an arbitrary block of text and add it to the current message. If the string contains header fields, the values will be added to the message header. Once the end of the header block is detected, all subsequent text is added to the body of the message.

Note that unlike the **Import** method, the **Parse** method does not clear the contents of the current message and may be called multiple times. Use the **Clear** method to clear the current message before calling **Parse** if necessary.

Example

The following example demonstrates the use of **Parse** to parse multiple blocks of data from a file. This example effectively does the same thing as calling the **Import** method:

MailMessage1.Clear

```
hFile = FreeFile()
Open strFileName For Input As hFile
nFileLength = LOF(hFile)

Do While nFileLength > 0
    '
    ' Read the contents of the file in 1K blocks; note that
    ' this is intentionally inefficient to demonstrate
    ' multiple calls to the Parse method.
    '
    cbBuffer = nFileLength: If cbBuffer > 1024 Then cbBuffer = 1024
    nFileLength = nFileLength - cbBuffer
    strBuffer = Input(cbBuffer, hFile)
    '
    ' Parse the string, adding to the current message
    '
    nError = MailMessage1.Parse(strBuffer)
    If nError > 0 Then
        MsgBox MailMessage1.LastErrorString, vbExclamation
        Exit Do
    End If
Loop
```

Close hFile

See Also

[Clear Method](#), [Import Method](#)

PurgeStore Method

Purge all deleted messages from the current message store.

Syntax

object.PurgeStore

Parameters

None.

Return Value

A value of zero is returned if the action was successful. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **PurgeStore** method purges all deleted messages from the message store. If the storage file has been opened in read-only mode or there are no messages marked for deletion, this method will take no action.

When the **CloseStore** method is called, the storage file will automatically be purged. To prevent deleted messages from being removed from the message store, use the **Reset** method.

See Also

[StoreFile Property](#), [CloseStore Method](#), [DeleteMessage Method](#), [OpenStore Method](#), [ReadStore Method](#), [WriteStore Method](#)

ReadStore Method

Retrieve a message from the message store, replacing the current message.

Syntax

object.ReadStore(*MessageIndex*)

Parameters

MessageIndex

An integer value which specifies the message that is to be removed from the message store. If this parameter is omitted, the current message as specified by the value of the **StoreIndex** property will be used.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **ReadStore** method reads the specified message from the message store, and the contents of that message will replace the current message. This method will update the current message index in the storage file.

See Also

[StoreCount Property](#), [StoreFile Property](#), [StoreIndex Property](#), [CloseStore Method](#), [DeleteMessage Method](#), [FindMessage Method](#), [ReplaceMessage Method](#), [WriteStore Method](#)

ReplaceMessage Method

Replace the specified message in the current message store.

Syntax

object.ReplaceMessage([*MessageIndex*])

Parameters

MessageIndex

An integer value which specifies the message that is to be replaced in the message store. If this parameter is omitted, the current message as specified by the value of the **StoreIndex** property will be used.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **ReplaceMessage** method replaces the specified message with a new message. The message number may be a message that has been previously marked for deletion. It is important to note that the change will not be reflected in the physical storage file until it has been closed. This method will update the current message index in the storage file.

The message store must be opened with write access. This method will fail if you attempt to replace a message from a storage file that has been opened for read-only access. If the application needs to replace messages in the message store, it is recommended that the file be opened for exclusive access using the **mimeStoreLock** option when calling the **OpenStore** method.

See Also

[StoreCount Property](#), [StoreIndex Property](#), [DeleteMessage Method](#), [PurgeStore Method](#), [ReadStore Method](#), [WriteStore Method](#)

Reset Method

Reset the internal state of the control.

Syntax

object.Reset

Parameters

None.

Return Value

None.

Remarks

The **Reset** method resets the internal state of the control. Property values are initialized to their internal defaults and any handles allocated by the control will be released. If a message store has been opened, it will be closed. If messages had been flagged for deletion from the current message store, they will not be purged.

See Also

[Initialize Method](#), [Uninitialize Method](#)

SetHeader Method

Set the value for the specified header in the current message part.

Syntax

object.SetHeader(*HeaderField*, *HeaderValue*)

Parameters

HeaderField

A string which specifies the name of the header field to create or modify. If the header field does not exist, then it will be created. If the header field exists, the current value will be overwritten.

HeaderValue

A string which specifies the value of the specified header field.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

See Also

[AllHeaders Property](#), [Part Property](#), [GetFirstHeader Method](#), [GetHeader Method](#), [GetNextHeader Method](#)

Uninitialize Method

Uninitialize the control and reset it to its default state.

Syntax

object.Uninitialize

Parameters

None.

Return Value

None.

Remarks

The **Uninitialize** method frees the memory allocated for the current message and resets the internal state of the control. This method is not typically used because any resources that have been allocated by an instance of the control will automatically be released when it is destroyed.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the control will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the control was created. An application should only call the **Uninitialize** method if it has explicitly called the **Initialize** method.

See Also

[Initialize Method](#)

WriteStore Method

Store the current message in the message store.

Syntax

object.WriteStore

Parameters

None.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **WriteStore** method will always append the current message to the storage file. If you want to replace a message in the message store, you should use the **ReplaceMessage** method. This method will update the value of the **StoreIndex** property to specify the message number for the new message that has been added to the storage file.

See Also

[StoreCount Property](#), [StoreFile Property](#), [StoreIndex Property](#), [CloseStore Method](#), [DeleteMessage Method](#), [FindMessage Method](#), [ReadStore Method](#), [ReplaceMessage Method](#)

Mail Message Control Events

Event	Description
OnError	This event occurs when a control error occurs

OnError Event

The **OnError** event is generated when a control error occurs.

Syntax

```
Sub object_OnError ( [Index As Integer,] ByVal ErrorCode As Variant, ByVal Description As Variant )
```

Remarks

This event occurs when an error occurs during a control action. Errors not generated by the control itself, such as errors related to the programming language or general component errors, do not trigger this event.

The ***ErrorCode*** argument specifies the last error that has occurred. If the error is network related, the error code values returned by the control correspond to those returned by the standard Windows Sockets library.

The ***Description*** argument is a string that describes the error.

See Also

[LastError Property](#), [LastErrorString Property](#), [ThrowError Property](#)

Message Character Sets

Value	Name	Code Page	Description
mimeCharsetUSASCII	us-ascii	20127	A character set which defines 7-bit printable characters with values ranging from 20h to 7Eh. An application which uses this character set has the broadest compatibility with most mail servers (MTAs) because it does not require the server to handle 8-bit characters correctly when the message is delivered.
mimeCharsetISO8859_1	iso-8859-1	28591	A character set for most western European languages such as English, French, Spanish and German. This character set is also commonly referred to as Latin-1. This character set is similar to Windows code page 1252 (Windows-1252), however there are differences such as the Euro symbol.
mimeCharsetISO8859_2	iso-8859-2	28592	A character set for most central and eastern European languages such as Czech, Hungarian, Polish and Romanian. This character set is also commonly referred to as Latin-2. This character set is similar to Windows code page 1250, however the characters are arranged differently.
mimeCharsetISO8859_3	iso-8859-3	28593	A character set for southern European languages such as Maltese and Esperanto. This character set was also used with the Turkish language, but it was superseded by ISO 8859-9 which is the preferred character set for Turkish. This character set is not widely used in mail messages and it is recommended that you use UTF-8 instead.
mimeCharsetISO8859_4	iso-8859-4	28594	A character set for northern European languages such as Latvian, Lithuanian and Greenlandic. This character set is not widely used in mail messages and it is recommended that you use UTF-8 instead.
mimeCharsetISO8859_5	iso-8859-5	28595	A character set for Cyrillic languages such as Russian, Bulgarian and Serbian. This character set was never widely adopted and most mail messages use either KOI8 or UTF-8 encoding.
mimeCharsetISO8859_6	iso-8859-6	28596	A character set for Arabic languages. Note that the application is responsible for displaying text that uses this character set. In particular, any display engine needs to be able to handle the reverse writing direction and analyze the

			context of the message to correctly combine the glyphs.
mimeCharsetISO8859_7	iso-8859-7	28597	A character set for the Greek language. This character set is also commonly referred to as Latin/Greek. This character set is no longer widely used and has largely been replaced with UTF-8 which provides more complete coverage of the Greek alphabet.
mimeCharsetISO8859_8	iso-8859-8	28598	A character set for the Hebrew language. Note that similar to Arabic, Hebrew uses a reverse writing direction. An application which displays this character should be capable of processing bi-directional text where a single message may include both right-to-left and left-to-right languages, such as Hebrew and English. In most cases it is recommended that you use UTF-8 instead of this character set.
mimeCharsetISO8859_9	iso-8859-9	28599	A character set for the Turkish language. This character set is also commonly referred to as Latin-5. This character set is nearly identical to ISO 8859-1, except that it replaces certain Icelandic characters with Turkish characters.
mimeCharsetISO8859_10	iso-8859-10	28600	A character set for the Danish, Icelandic, Norwegian and Swedish languages. This character set is also commonly referred to as Latin-6 and is similar to ISO 8859-4.
mimeCharsetISO8859_13	iso-8859-13	28603	A character set for Baltic languages. This character set is also commonly referred to as Latin-7. This character set is similar to ISO 8859-4, except it adds certain Polish characters and does not support Nordic languages.
mimeCharsetISO8859_14	iso-8859-14	28604	A character set for Gaelic languages such as Irish, Manx and Scottish Gaelic. This character set is also commonly referred to as Latin-8. This character set replaced ISO 8859-12 which was never fully implemented.
mimeCharsetISO8859_15	iso-8859-15	28605	A character set for western European languages. This character set is also commonly referred to as Latin-9 and is nearly identical to ISO8859-1 except that it replaces lesser-used symbols with the Euro sign and some letters.
mimeCharsetISO2022_JP	iso-2022-jp	50220	A multi-byte character encoding for Japanese that is widely used with mail messages. This is a 7-bit encoding where all characters start with ASCII and uses escape sequences to switch to the double-byte character sets.

mimeCharsetISO2022_KR	iso-2022-kr	50225	A multi-byte character encoding for Korean which encodes both ASCII and Korean double-byte characters. This is a 7-bit encoding which uses the shift in and shift out control characters to switch to the double-byte character set.
mimeCharsetISO2022_CN	x-cp50227	50227	A multi-byte character encoding for Simplified Chinese which encodes both ASCII and Chinese double-byte characters. This is a 7-bit encoding which uses the shift in and shift out control characters to switch to the double-byte character set.
mimeCharsetKOI8R	koi8-r	20866	A character set for Russian using the Cyrillic alphabet. This character set also covers the Bulgarian language. Most mail messages in the Russian language use this character set or UTF-8 instead of ISO 8859-5, which was never widely adopted.
mimeCharsetKOI8U	koi8-u	21866	A character set for Ukrainian using the Cyrillic alphabet. This character set is similar to the KOI8-R character set, but replaces certain symbols with Ukrainian letters. Most mail messages in the Ukrainian language use this character set or UTF-8 instead of ISO 8859-5, which was never widely adopted.
mimeCharsetGB2312	x-cp20936	20936	A multi-byte character encoding which can represent ASCII and simplified Chinese characters. It has been superseded by GB18030, however it remains widely used in China.
mimeCharsetGB18030	gb18030	54936	A Unicode transformation format which can represent all Unicode code points and supports both simplified and traditional Chinese characters. It is backwards compatible with GB2312 and supersedes that character set.
mimeCharsetBIG5	big5	950	A multi-byte character set that supports both ASCII characters and traditional Chinese characters. It is widely used in Taiwan, Hong Kong and Macau. It is no longer commonly used in China, which has developed GB18030 as a standard encoding. Microsoft's implementation of Big5 on Windows does not support all of the extensions and is missing certain code points.
mimeCharsetUTF7	utf-7	65000	A Unicode transformation format that uses variable-length character encoding to represent Unicode text as a stream of ASCII characters that are safe to transport between

			mail servers that only support 7-bit printable characters. It is primarily used as an alternative to UTF-8 when quoted-printable or base64 encoding is not desired.
mimeCharsetUTF8	utf-8	65001	A Unicode transformation format that uses multi-byte character sequences to represent Unicode text. It is backwards compatible with the ASCII character set, however because it uses 8-bit text, it is recommended that you use either quoted-printable or base64 encoding to ensure compatibility with mail servers that do not support 8-bit characters.
mimeCharsetUTF16	utf-16le	N/A	A 16-bit Unicode format that represents each character as a 16-bit value in little endian byte order. This character set is not widely used in mail messages and it is recommended that you use UTF-8 instead. UTF-16 characters in big endian byte order are not supported.

Remarks

When composing a new message, it is recommended that you always use UTF-8 as the character set encoding which ensures broad compatibility with most applications. The other character sets are primarily used when parsing messages generated by other applications. Internally, all message headers and text are processed as UTF-8 and returned as Unicode strings.

In addition to the character sets listed above, the control will recognize additional character sets which correspond to specific Windows code pages, as well several variants. These additional character sets are included for compatibility with other applications; they are not defined because they should not be used when composing new messages.

It is important to note that while certain Windows character sets are similar to standard ISO character sets, they are not identical. For example, although the Windows-1252 character set is nearly identical to ISO 8859-1, they are not interchangeable. Some legacy applications make the error of representing Windows ANSI character sets as 8-bit ISO character sets, which can result in errors when converting them to Unicode. This is something to be aware of when encoding and decoding text generated by older applications. Before the widespread adoption of UTF-8, it was particularly common for legacy Windows mail clients to default to using Windows-1252 for text and label it as using ISO 8859-1.

Although the control supports UTF-16, it is recommended you use UTF-8 instead. Text which uses UTF-16 will always be base64 encoded, and some mail clients may not recognize it as a valid character set. If the message does not specify if big endian or little endian byte order is used, the library will default to little endian. When UTF-16 is used when composing a new message, it will always use little endian byte order.

If you are using this control with Visual Basic 6.0, be aware that the IDE does not provide complete support for Unicode text. Although the control uses Unicode internally, if a header or message body contains characters which cannot be displayed using the current system ANSI code page, the text can appear to be corrupted when examining the string using the debugger. If a message contains text which uses a character set other than the system default, you must use controls which are Unicode aware to display the text, such as the Microsoft InkEdit control. The standard TextBox and other common controls in Visual Basic do not support Unicode.

News Feed Control

Retrieve and process the contents of a syndicated news feed.

Reference

- [Properties](#)
- [Methods](#)
- [Events](#)
- [Error Codes](#)

Control Information

Object Name	NewsFeedCtl.NewsFeed
File Name	CSRSSX12.OCX
Version	12.0.3024.1286
ProgID	SocketTools.NewsFeed.12
ClassID	C4870EDE-83E6-45FA-B111-7E593EEACBF9
Threading Model	Apartment
Help File	CST12CTL.CHM
Dependencies	None

Overview

Really Simple Syndication (RSS) is a collection of standardized formats that are used to publish information about content that is frequently changed. A news feed is published in XML format, which contains one or more items that includes summary text, hyperlinks to source content and additional metadata that is used to describe the item. News feeds can be used for a variety of purposes, including providing updates for weblogs, news headlines, video and audio content. RSS can also be used for other purposes, such as a software updates, where new updates are listed as items in the feed.

News feeds can be accessed remotely from a web server, or locally as an XML formatted text file. The source of the feed is determined by the URI scheme that is specified. If the http or https scheme is specified, then the feed is retrieved from a web server. If the file scheme is used, the feed is considered to be local and is accessed from the disk or local network. The News Feed control provides an interface that enables you to open a feed by URL and iterate through each of the items in the feed or search for a specific feed item. The control also includes a method that can be used to parse a string that contains XML data in RSS format, where the feed may have been retrieved from other sources such as a database.

Requirements

The SocketTools ActiveX Edition components are self-registering controls that are compatible with any programming language that supports the Component Object Model (COM) and the ActiveX control specification. If you are using Visual Basic 6.0, Service Pack 6 (SP6) is required. We recommend installing all available updates for your development tools. Although the Visual Basic 6.0 runtime is

supported on Windows 11, the IDE itself is no longer officially supported by Microsoft. Legacy IDEs and compilers may also require elevated (administrator) privileges to run properly.

The ActiveX controls are supported on Windows 7, Windows Server 2008 R2, and later versions of both desktop and server editions of Windows. For Windows 7, Service Pack 1 (SP1) is the minimum requirement. For Windows 8 systems, the 8.1 update must be installed. On ARM-based platforms, the minimum supported version is Windows 10 build 1709.

SocketTools includes components for both 32-bit (x86) and 64-bit (x64) Windows platforms. All modern versions of Windows are 64-bit, but we continue to include 32-bit components for compatibility with legacy development tools such as Visual Basic 6.0. We also provide native ARM64 ActiveX controls for systems running Windows on ARM. Note that 32-bit applications on ARM run using x86 emulation, and Microsoft no longer supports native ARM32 applications.

If you are using VBScript, Visual Basic for Applications (VBA), or another scripting environment on an ARM-based system, be aware that 64-bit hosts will require ARM64 components, while 32-bit hosts will use x86 components under emulation. This includes applications created with Visual Basic 6.0. To reduce deployment complexity and avoid confusion, SocketTools does not include ARM32 ActiveX controls in its standard redistribution packages but they are available on request for legacy or specialized scenarios.

Distribution

When you distribute an application that uses this control, you can either install the file in the same folder as your application executable or as a shared component in the appropriate system folder. If you install the control in the system folder, it is important that you distribute the correct version for the target platform and it must be registered. If you install the control in the same folder as your executable, it is recommended that you use registration-free activation or COM redirection to ensure that the correct version of the control is loaded by the application.

News Feed Control Properties

Property	Description
Category	Gets the category or categories that the news feed channel belongs to
Copyright	Gets the copyright notice for the news feed
Description	Gets a description of the news feed channel
Editor	Gets the email address of the person responsible for managing the content of the feed
FeedVersion	Gets the version of the news feed
Generator	Gets the name of the application that generated the news feed
ImageLink	Gets the hyperlink for the image associated with the news feed
ImageTitle	Gets the title for the image associated with the news feed
ImageUrl	Gets the URL for the image associated with the news feed
IsInitialized	Determine if the control has been initialized
ItemAuthor	Gets the email address of the person who authored the current news item
ItemComments	Gets the URL that links to further discussion about the current news item
ItemCount	Gets the number of news items in the feed channel
ItemEnclosure	Gets the URL that links to a file associated with the current news item
ItemGuid	Gets a value that uniquely identifies the current news item in the feed channel
ItemId	Gets the numeric ID for the current news item
ItemLink	Gets the URL that links to additional information about the current news item
ItemPublished	Gets the date and time that the current news item was published
ItemSource	Gets a URL that links to the original news feed that contained the current item
ItemText	Gets the text that describes the current news item
ItemTitle	Gets the title of the current news item
Language	Gets the language that the news feed channel is written in, using standard language codes
LastBuild	Gets the date and time that the news feed was last modified
LastError	Gets and sets the last error that occurred on the control
LastErrorString	Return a description of the last error to occur
LinkUrl	Gets the URL that links to the website corresponding to the news feed
LocalFeed	Return whether the news feed was loaded from a file on the local system or a server
Published	Gets the date and time that the news feed was published
ThrowError	Enables or disables error handling by the application
Timeout	Gets and sets the amount of time until a blocking operation fails
TimeToLive	Gets a value which specifies the frequency in seconds at which the feed should be refreshed
Title	Gets the title of the news feed

Trace	Enable or disable socket function level tracing
TraceFile	Specify the socket function trace output file
TraceFlags	Gets and sets the socket function tracing flags
URL	Gets the URL for the current news feed
Version	Gets the current version of the control
Webmaster	Gets the email address of the person responsible for technical issues related to the news feed

Category Property

Gets a value which specifies the category or categories that the channel belongs to.

Syntax

object.Category

Remarks

The **Category** property is used to identify the category that the news feed channel belongs to. This is an optional value that may not be defined, in which case the property will return an empty string.

Data Type

String

See Also

[Description Property](#), [Language Property](#), [LinkUrl Property](#), [Published Property](#), [Title Property](#)

Copyright Property

Gets a value which specifies a copyright notice for the content.

Syntax

object.Copyright

Remarks

The **Copyright** property returns a string which contains a copyright notice for the news feed. If the feed does not specify a copyright, then this property will return an empty string.

Data Type

String

See Also

[Description Property](#), [Language Property](#), [LinkUrl Property](#), [Published Property](#), [Title Property](#)

Description Property

Gets a value which describes the news feed channel.

Syntax

object.Description

Remarks

The **Description** property returns a string that provides an overview of the news feed and the type of information that is provided. If a description of the feed has not been specified, this property will return an empty string. Note that a news feed which conforms to the standard specification requires a description.

Data Type

String

See Also

[Language Property](#), [LinkUrl Property](#), [Published Property](#), [Title Property](#)

Editor Property

Gets a value which identifies the person responsible for managing the content of the news feed.

Syntax

object.Editor

Remarks

The **Editor** property returns a string that identifies the person responsible for managing the content of the news feed. If this property is defined, it is typically the name and email address of the feed editor. If an editor has not been specified, this property will return an empty string.

Data Type

String

See Also

[Language Property](#), [LinkUrl Property](#), [Published Property](#), [Title Property](#)

FeedVersion Property

Gets a value which identifies the version of the news feed.

Syntax

object.FeedVersion

Remarks

The **FeedVersion** property returns a string that identifies the version of the news feed. This can be used by an application to determine which version of the RSS specification was used to create the feed. The current version of the specification is 2.0.

Data Type

String

See Also

[Language Property](#), [LinkUrl Property](#), [Published Property](#), [Title Property](#)

Generator Property

Gets a value which identifies the application that was used to create the news feed.

Syntax

object.Generator

Remarks

The **Generator** property returns a string which identifies the application that was used to create the news feed. If the feed does not specify a generator, then this property will return an empty string.

Data Type

String

See Also

[Description Property](#), [Language Property](#), [LinkUrl Property](#), [Published Property](#), [Title Property](#)

ImageLink Property

Gets a value which specifies a URL to the website corresponding to the news feed.

Syntax

object.ImageLink

Remarks

The **ImageLink** property returns a string that specifies a URL to the website corresponding to the channel. In most cases, this is the same URL that is specified by the **LinkUrl** property. If an image link has not been specified, this property will return an empty string.

Data Type

String

See Also

[ImageTitle Property](#), [ImageUrl Property](#), [LinkUrl Property](#)

ImageTitle Property

Gets a value which describes the image associated with the news feed.

Syntax

object.ImageTitle

Remarks

The **ImageTitle** property returns a string that identifies the image associated with the channel. This is usually a brief description of the image, and may be the same as the value specified by the **Title** property. If an image title has not been specified, this property will return an empty string.

Data Type

String

See Also

[ImageLink Property](#), [ImageUrl Property](#), [Title Property](#)

ImageUrl Property

Gets a value which specifies a URL for the image associated with the news feed.

Syntax

object.ImageUrl

Remarks

The **ImageUrl** property returns a string that specifies a URL for the image associated with the channel. An application can download this image and display it with the contents of the news feed. If an image URL has not been specified, this property will return an empty string.

Data Type

String

See Also

[ImageLink Property](#), [ImageTitle Property](#)

ItemAuthor Property

Gets a value which identifies the author of the current news feed item.

Syntax

object.ItemAuthor

Remarks

The **ItemAuthor** property returns a string which specifies an email address. If this property is defined, it is typically the name and address of the person who created the content that the item links to. If the author is not specified, this property will return an empty string.

Data Type

String

See Also

[ItemGuid Property](#), [ItemLink Property](#), [ItemText Property](#), [ItemTitle Property](#)

ItemComments Property

Gets a value which specifies a URL that links to further discussion about the current item.

Syntax

object.ItemComments

Remarks

The **ItemComments** property returns a string which specifies a URL that links to further discussion about the item. Typically this is a link to the comment area of a weblog or a forum topic specific to the item. If a comment link is not specified, this property will return an empty string.

Data Type

String

See Also

[ItemAuthor Property](#), [ItemGuid Property](#), [ItemLink Property](#), [ItemText Property](#), [ItemTitle Property](#)

ItemCount Property

Gets value which specifies the number of news items in the channel.

Syntax

object.ItemCount

Remarks

The **ItemCount** property returns an integer value which specifies the number of items in the current news feed channel. This property can be used in conjunction with the **GetItem** method to enumerate through the available news feed items.

Data Type

Integer (Int32)

Example

The following example accesses a remote feed and enumerates each news item, populating the contents of a ListBox control with its title.

```
Dim strFeed As String
Dim nIndex As Long
Dim nError As Long

strFeed = "http://sockettools.com/rss/news.xml"
ListBox1.Clear

nError = NewsFeed1.Open(strFeed)
If nError > 0 Then
    MsgBox NewsFeed1.LastErrorString, vbExclamation
    Exit Sub
End If

Label1.Caption = NewsFeed1.ItemCount & " news items, published on " &
NewsFeed1.Published

For nIndex = 1 To NewsFeed1.ItemCount
    nError = NewsFeed1.GetItem(nIndex)
    If nError > 0 Then
        MsgBox NewsFeed1.LastErrorString, vbExclamation
        Exit For
    End If
    ListBox1.AddItem NewsFeed1.ItemTitle
Next
```

See Also

[ItemGuid Property](#), [ItemId Property](#), [ItemText Property](#), [GetItem Method](#)

ItemEnclosure Property

Gets a value which specifies a URL that links to a file related to the item.

Syntax

object.ItemEnclosure

Remarks

The **ItemEnclosure** property returns a string which specifies a URL that links to an attached document for the news feed item. This is similar to an attachment in an email message, however instead of the item containing the contents of the attached file, it only specifies a link to the file. Enclosures are most commonly used with podcasting where an item is linked to an audio or video file, however the link may reference any type of file. If there is no enclosure specified for the current item, this property will return an empty string.

Data Type

String

See Also

[ItemAuthor Property](#), [ItemGuid Property](#), [ItemLink Property](#), [ItemText Property](#), [ItemTitle Property](#)

ItemGuid Property

Gets a value which uniquely identifies the current news item in the channel.

Syntax

object.ItemGuid

Remarks

The **ItemGuid** property returns a string which uniquely identifies the current news item. If this property is defined, it is guaranteed to be a unique, persistent value. It is important to note that this string does not have to be a standard GUID reference number, it can be any unique string. In many cases it is the same value as the hyperlink returned by the **ItemLink** property, although an application should never depend on this behavior. If there is no unique identifier associated with the current item, this property will return an empty string.

Data Type

String

See Also

[ItemAuthor Property](#), [ItemId Property](#), [ItemLink Property](#), [ItemText Property](#), [ItemTitle Property](#)

ItemId Property

Gets an numeric value which identifies the current news item in the channel.

Syntax

object.ItemId

Remarks

The **ItemId** property returns an integer that is an index into the list of available news items. It is not persistent and the ID for a specific news item may change when the news feed is refreshed or opened at a later point. To uniquely identify a news item in the channel, use the **ItemGuid** property. To retrieve a news feed item, use the **GetItem** method.

Data Type

Integer (Int32)

See Also

[ItemAuthor Property](#), [ItemGuid Property](#), [ItemText Property](#), [GetItem Method](#)

ItemLink Property

Gets a value which specifies a URL that links to additional information related to the current item.

Syntax

object.ItemLink

Remarks

The **ItemLink** property returns a string which specifies a URL that provides additional information about a news item. If the news item summarizes the contents of an article, this property typically provides a link to the complete article. If a link is not specified, this property will return an empty string.

Data Type

String

See Also

[ItemAuthor Property](#), [ItemGuid Property](#), [ItemText Property](#), [ItemTitle Property](#)

ItemPublished Property

Gets a value which specifies the date and time the current news item was published.

Syntax

object.ItemPublished

Remarks

The **ItemPublished** property returns a string which specifies the date and time that the news item was published. If the news item does not specify the publish date, this property will return an empty string. The date and time value returned is in the standard format used by the current locale.

Data Type

String

See Also

[ItemAuthor Property](#), [ItemGuid Property](#), [ItemLink Property](#), [ItemText Property](#), [ItemTitle Property](#)

ItemSource Property

Gets a value which identifies the source of the current news item.

Syntax

object.ItemSource

Remarks

The **ItemSource** property returns a string which specifies a URL for the original feed that contained the news item. This is typically used to propagate credit for news items that are aggregated by a third-party and re-published in their own channel. If the source is not specified, this property will return an empty string.

Data Type

String

See Also

[ItemAuthor Property](#), [ItemGuid Property](#), [ItemLink Property](#), [ItemText Property](#), [ItemTitle Property](#)

ItemText Property

Gets a value which provides a summary or description of the current news item.

Syntax

object.ItemText

Remarks

The **ItemText** property returns a string that contains a summary of the current news item. This property may return either plain text or HTML formatted text. If no text has been specified for the current item, this property will return an empty string. Although it is not required for a news item to have a description, a feed that conforms to the standard must have either a description of the item or a title, which is returned by the **ItemTitle** property.

Data Type

String

See Also

[ItemAuthor Property](#), [ItemGuid Property](#), [ItemLink Property](#), [ItemTitle Property](#)

ItemTitle Property

Gets a value which specifies the title for the current news item.

Syntax

object.ItemTitle

Remarks

The **ItemTitle** property returns a string which specifies a title for the news item. If no title has been specified, this property will return an empty string. Although it is not required for a news item to have a title, a feed that conforms to the standard must have either a title or a description of the item, which is returned by the **ItemText** property.

Data Type

String

See Also

[ItemAuthor Property](#), [ItemGuid Property](#), [ItemLink Property](#), [ItemText Property](#)

Language Property

Gets a value which identifies the language the news feed is written in.

Syntax

object.Language

Remarks

The **Language** property returns a string which defines the language the channel is written in, using the standard language codes or an empty string if the language is not defined. This property typically returns standardized language codes, however the value actually returned depends on the content of the feed. If the news feed does not define this property, then it is generally presumed to be written in English.

Data Type

String

See Also

[Description Property](#), [Language Property](#), [LinkUrl Property](#), [Published Property](#), [Title Property](#)

LastBuild Property

Gets a value which specifies the date and time that the content of the news feed was last modified.

Syntax

object.LastBuild

Remarks

The **LastBuild** property returns a string which specifies the date and time that the feed was last modified. If the feed does not define this value, this property will return an empty string. The date and time value returned is in the standard format used by the current locale.

Data Type

String

See Also

[Description Property](#), [LinkUrl Property](#), [Published Property](#), [Title Property](#)

LastError Property

Gets and sets the last error that occurred on the control.

Syntax

object.**LastError** [= *value*]

Remarks

The **LastError** property can be read to determine the last error that occurred for this control. If a value is assigned to this property, it must either be zero to clear the error or a valid error code for the control.

Data Type

Integer (Int32)

See Also

[LastErrorMessage Property](#), [ThrowError Property](#), [OnError Event](#)

LastErrorString Property

Return a description of the last error to occur

Syntax

object.LastErrorString

Remarks

The **LastErrorString** property returns a description of the last error that occurred. This can be used to display a meaningful error message to a user, rather than just the numeric value returned by the **LastError** property.

Data Type

String

See Also

[LastError Property](#), [ThrowError Property](#), [OnError Event](#)

LinkUrl Property

Gets a value which specifies a URL to the website corresponding to the channel.

Syntax

object.LinkUrl

Remarks

The **LinkUrl** property returns a string which specifies a URL to the website corresponding to the channel. Note that this is not the URL of the news feed itself. Typically it is a link to the home page of the site which owns the news feed. If a link has not been specified, this property will return an empty string. Note that a strictly conforming news feed requires a valid link URL.

Data Type

String

See Also

[Description Property](#), [LastBuild Property](#), [Published Property](#), [Title Property](#)

LocalFeed Property

Gets a value which specifies if the news feed was opened on the local system.

Syntax

object.LocalFeed

Remarks

This property will return true if the news feed was accessed from the local system by specifying a file name to the **Open** method. If the news feed was accessed from a remote web server, this property will return false.

Data Type

Boolean

See Also

[Url Property](#), [Open Method](#)

Published Property

Gets a value which specifies the date and time that the news feed was published.

Syntax

object.Published

Remarks

The **Published** property returns a string which specifies the date and time that the feed was published. For example, a feed that is associated with a weekly print publication may update this value once per week. Note that this is not necessarily the date that the feed was last modified. If the feed channel does not specify the publish date, this property will return an empty string. The date and time value returned is in the standard format used by the current locale.

Data Type

String

See Also

[Description Property](#), [LastBuild Property](#), [LinkUrl Property](#), [Title Property](#)

ThrowError Property

Enables or disables error handling by the application.

Syntax

object.**ThrowError** = { True | False }

Remarks

Error handling for methods can be performed using either return codes or exceptions, depending on the value of this property.

If the **ThrowError** property is set to False, methods will return a status value indicating success or failure. Applications should check the return value of each method and use the **LastError** and **LastErrorString** properties to determine the cause of any error.

If the **ThrowError** property is set to True, errors occurring within the control will be raised to the host application as ActiveX exceptions. In addition, the **OnError** event will fire. This allows applications to use language-specific exception handling mechanisms, such as Visual Basic error handling, instead of checking individual return values after each method call.

Even when the **ThrowError** property is set to True, the **LastError** and **LastErrorString** properties will still be updated with information about the most recent error.

If an error occurs while accessing a property value, an exception will be raised regardless of the value of the **ThrowError** property. However, the **OnError** event will not be fired for property access errors.

Data Type

Boolean

Example

The following example handles errors by checking the return code of a method:

```
NewsFeed1.ThrowError = False
nError = NewsFeed1.Open(strFeedUrl)

If nError > 0 Then
    MsgBox NewsFeed1.LastErrorString, vbExclamation
    Exit Sub
End If
```

The following example handles errors by throwing them to the container:

```
On Error Resume Next: Err.Clear

NewsFeed1.ThrowError = True
NewsFeed1.Open strHostName

If Err.Number <> 0
    MsgBox Err.Description, vbExclamation
    Exit Sub
End If
On Error GoTo 0
```

See Also

[LastError Property](#), [LastErrorString Property](#), [OnError Event](#)

Timeout Property

Gets and sets the amount of time until a blocking operation fails.

Syntax

object.Timeout [= *seconds*]

Remarks

Setting the **Timeout** property specifies the number of seconds until a blocking operation fails and the control returns an error.

Note that the **Timeout** property also determines the amount of time the control will spend attempting to connect to a server. If a connection is not established within the given time period, the connection attempt will fail.

Data Type

Integer (Int32)

TimeToLive Property

Gets a value which specifies the frequency in seconds at which the feed should be refreshed.

Syntax

object.TimeToLive

Remarks

The **TimeToLive** property is an integer value that specifies the frequency in seconds at which the feed should be refreshed to obtain updated information. Not all feeds specify a time-to-live, in which case this property will have a value of zero.

The value of the **TimeToLive** property should be considered advisory, and not all news feeds will provide this value. If the news feed does provide this value, it is recommended that you consider it to be the minimum interval at which you will poll the site for updates to the feed.

Data Type

Integer (Int32)

See Also

[Open Method](#), [Refresh Method](#)

Title Property

Gets a value which specifies the name of the news feed channel.

Syntax

object.Title

Remarks

The **Title** property returns a string which specifies the title of the news feed channel. If the content of the news feed corresponds to a website, this is value returned by this property is typically the same as the title of the website. If a title has not been specified, this property will return an empty string. Note that a strictly conforming news feed requires a title.

Data Type

String

See Also

[Description Property](#), [LastBuild Property](#), [Published Property](#)

Trace Property

Enable or disable network function level logging.

Syntax

`object.Trace` [= { True | False }]

Remarks

The **Trace** property is used to enable or disable the logging of network function calls. When enabled, each function call is logged to a file, including the function parameters, return value and error code if applicable. This facility can be enabled and disabled at run time, and the trace log file can be specified by setting the **TraceFile** property. All function calls that are being logged are appended to the trace file, if it exists. If no log file exists when tracing is enabled, the file is created.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

Data Type

Boolean

See Also

[TraceFile Property](#), [TraceFlags Property](#)

TraceFile Property

Gets and sets the name of the file to use when logging network function calls.

Syntax

`object.TraceFile [= filename ]`

Remarks

The **TraceFile** property is used to specify the name of the file that is created when logging is enabled. If this property is set to an empty string (the default value), then a file named **SocketTools.log** is created in the current user's Documents folder. It is recommended that you always specify a complete path to the log file. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

If the file exists, the output is appended to the file, otherwise the file is created. Since logging is enabled per-process, the log file is shared by all instances of the controls being used. If you create multiple instances of the control, you only need to enable logging for a single instance. Because log files can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "0x". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxx:xxxx:xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, the control is attempting to connect to a system with the IPv4 address 192.0.0.1 on port 1234.

If the log file cannot be created, or the user does not have permission to modify an existing file, the error is silently ignored and no output will be generated.

Data Type

String

See Also

TraceFlags Property

Gets and sets the network function logging flags.

Syntax

object.TraceFlags [= *flags*]

Remarks

The **TraceFlags** property is used to specify the type of information written to the trace file when socket function tracing is enabled. The following values may be used:

Value	Description
dnsTraceInfo	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
dnsTraceError	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
dnsTraceWarning	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
dnsTraceHexDump	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
dnsTraceTruncate	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.

Since logging is enabled per-process, the trace flags are shared by all instances of the control being used. If multiple controls have tracing enabled, the **TraceFlags** property should be set to the same value for each control. Changing the trace flags for any one instance of the control will affect the logging performed for all other instances used by the application.

Warnings are generated when a non-fatal error is returned by a Windows Sockets function. For example, if data is being written through the control and an error indicating that the operation would block is returned, only a warning is logged since the application simply needs to attempt to write the data at a later time.

Data Type

Integer (Int32)

See Also

[Trace Property](#), [TraceFile Property](#)

URL Property

Gets and sets a value which specifies the news feed URL.

Syntax

object.URL [= *url*]

Remarks

The **URL** property returns a string which specifies a URL to the news feed. This may be either an http:// or https:// URL to specify a news feed on a web server, or it may be a file:// URL that specifies a local XML file that contains the news feed.

Data Type

String

See Also

[Description Property](#), [LastBuild Property](#), [Published Property](#), [Title Property](#)

Version Property

Return the current version of the control.

Syntax

object.Version

Remarks

The **Version** property returns the current version of the object. This can be used by an application for validation purposes. The version returned is composed of four numbers, separated by periods. The first number is the major version number, the second number is the minor version number, the third is the build number and the fourth is the revision number.

Data Type

String

See Also

[FeedVersion Property](#)

Webmaster Property

Gets a value which identifies the person responsible for technical issues related to the news feed.

Syntax

object.**Webmaster**

Remarks

The **Webmaster** property returns a string which contains an email address. If this value is defined in the news feed, it is typically the address of a system administrator responsible for the server that hosts the news feed. If the webmaster is not specified, this property will return an empty string.

Data Type

String

See Also

[Description Property](#), [Language Property](#), [LinkUrl Property](#), [Published Property](#), [Title Property](#)

News Feed Control Methods

Method	Description
Close	Close the current news feed
FindItem	Search for an item in the news feed channel which matches the unique identifier
GetItem	Set the current news item to the specified item number
GetProperty	Get the value of a property for the specified item in the news feed
Initialize	Initialize the control and validate the runtime license key
Open	Open the specified news feed and load the first news item
Parse	Parse the contents of a news feed and load the first news item
Refresh	Refresh the current news feed, reloading the news channel items
Reset	Reset the internal state of the control
Store	Store the contents of the news feed in an XML formatted text file
Uninitialize	Uninitialize the control and release any system resources that were allocated

Close Method

Close the current news feed.

Syntax

object.Close

Parameters

None.

Return Value

A value of zero is returned if the feed was closed successfully. Otherwise, a non-zero error code is returned which indicates the cause of the failure. If the method fails, the value of the **LastError** property can be used to determine cause of the failure.

Remarks

The **Close** method must be called whenever the application has completed processing the news feed. Information about the current news feed item will be cleared whenever this method is called, resetting the channel and item related properties back to their default values.

See Also

[FindItem Method](#), [GetItem Method](#), [Open Method](#), [Parse Method](#), [Store Method](#)

FindItem Method

Search for an item in the news feed channel which matches the unique identifier.

Syntax

object.FindItem(*Value*, [*Options*])

Parameters

Value

A string which specifies the value of the news item being searched for. This value should uniquely identify the item in the feed, and this parameter cannot be an empty string.

Options

An optional numeric parameter that specifies one or more options when searching for a news item. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
rssFindGuid	Search the feed for an item with a matching GUID property value. This is the default option, and is the only item property that is guaranteed to be unique in the feed. The search is case-sensitive, requiring that the Value parameter match the GUID property value for the news item exactly.
rssFindLink	Search the feed for items with a matching link property value. For feeds that do not specify a GUID property, this is the recommended option for searching for an item. The search is not case-sensitive.
rssFindTitle	Search the feed for items with a matching title. This option should not be used if you must ensure that the item returned is unique in the feed because there may be multiple items with the same title in the feed. The search is not case-sensitive.
rssFindPubDate	Search the feed for items with a matching publishing date. This option should not be used if you must ensure that the item returned is unique in the feed because more than one item may have the same publishing date. The format of the date string must match the standard format used with the RSS protocol and the match is not case-sensitive.

Return Value

A value of zero is returned if the news item was found. Otherwise, a non-zero error code is returned which indicates the cause of the failure. If the method fails, the value of the **LastError** property can be used to determine cause of the failure.

Remarks

The **FindItem** method searches for an item in the news feed channel which matches the unique identifier (GUID) value and returns information about that item. If this method is successful, the current news item is changed to the item that was found and property values such as **ItemLink** and **ItemText** will be updated. If this method fails, the current news item is not changed.

It is recommended that you use this method with news feeds that are using version 2.0 or later of the RSS specification. If the feed uses an earlier version, items may not include a GUID property. It is also possible that a feed may omit the GUID property even though it is considered a requirement for the

current RSS specification. For the broadest compatibility with all news feeds, an application should not depend on being able to search for a specific news feed item by its GUID.

See Also

[Close Method](#), [GetItem Method](#), [Open Method](#), [Parse Method](#)

GetItem Method

Set the current news item to the specified item number.

Syntax

object.GetItem(*ItemId*)

Parameters

ItemId

An integer value which specifies item in the news feed channel.

Return Value

A value of zero is returned if the news item was selected. Otherwise, a non-zero error code is returned which indicates the cause of the failure. If the method fails, the value of the **LastError** property can be used to determine cause of the failure.

Remarks

The **GetItem** method is used to select the current news item in the feed. If this method is successful, the current news item is changed to the specified value and property values such as **ItemLink** and **ItemText** will be updated. If this method fails, the current news item is not changed.

The item number is an index into the list of available news items in the current news feed. The first news item is one, and it increments for each additional item in the feed. If *ItemId* parameter is zero or specifies a value larger than the number of items in the feed, this method will fail. The **ItemId** property returns the value of the currently selected news item.

If this method fails, it typically indicates that the *ItemId* parameter is invalid or that the feed does not contain any valid news items. The **ItemCount** property can be used to determine the number of items contained in the news feed channel.

Example

The following example accesses a remote feed and enumerates each news item, populating the contents of a ListBox control with its title.

```
Dim strFeed As String
Dim nIndex As Long
Dim nError As Long

strFeed = "http://sockettools.com/rss/news.xml"
ListBox1.Clear

nError = NewsFeed1.Open(strFeed)
If nError > 0 Then
    MsgBox NewsFeed1.LastErrorString, vbExclamation
    Exit Sub
End If

Label1.Caption = NewsFeed1.ItemCount & " news items, published on " &
NewsFeed1.Published

For nIndex = 1 To NewsFeed1.ItemCount
    nError = NewsFeed1.GetItem(nIndex)
    If nError > 0 Then
        MsgBox NewsFeed1.LastErrorString, vbExclamation
```

```
Exit For
End If
ListBox1.AddItem NewsFeed1.ItemTitle
Next
```

See Also

[ItemCount Property](#), [ItemId Property](#), [Close Method](#), [FindItem Method](#), [Open Method](#), [Parse Method](#)

GetProperty Method

Get the value of a property for the current item in the news feed.

Syntax

object.GetProperty(Property, Value)

Parameters

Property

A string which specifies the name of the custom property to retrieve the value for.

Value

A string that is passed by reference which will contain the property value when the method returns.

Return Value

A value of zero is returned if the property was specified in the news item. Otherwise, a non-zero error code is returned which indicates the cause of the failure. If the method fails, the value of the **LastError** property can be used to determine cause of the failure.

Remarks

The **GetProperty** method is primarily used with custom item properties that may be used with extensions to the news feed. The standard properties for an news feed item such as the title, link and description can be access using properties such as **ItemTitle**, **ItemLink** and **ItemText**. However, if items in the feed contain custom properties that are not part of the standard RSS format, this method can be used to obtain those values.

See Also

[Close Method](#), [GetItem Method](#), [Open Method](#), [Parse Method](#)

Initialize Method

Initialize the control and validate the runtime license key.

Syntax

```
object.Initialize( [LicenseKey] )
```

Parameters

LicenseKey

An optional string value which specifies a runtime license key used to initialize the control. If the license key is omitted or passed as an empty string, a development license must be installed on the local system.

Return Value

A value of zero is returned if the control was initialized successfully. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

This method dynamically loads other system libraries and allocates thread local storage. In most cases, it is not necessary to call this method directly because it is automatically invoked when an instance of the control is created by the container. However, if the control is created dynamically using **CreateObject** or a similar method, this must be the first method that is called before you attempt to modify any property values or invoke other methods. Failure to initialize the control may result in subsequent errors and/or cause an exception to be raised.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the control will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the control was created.

If the control is being used within another DLL, it is important that you do not attempt to create an instance of the control or call the **Initialize** method from within the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is written in C++ and it is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for any static and global C++ objects and has the same restrictions.

Example

```
Set rssFeed = CreateObject("SocketTools.NewsFeed.12")

nError = rssFeed.Initialize(strLicenseKey)
If nError > 0 Then
    MsgBox "Unable to initialize SocketTools component"
End
End If
```

See Also

[IsInitialized Property](#), [Open Method](#), [Parse Method](#), [Uninitialize Method](#)

Open Method

Open the specified news feed and select the first news item.

Syntax

object.Open(*FeedUrl*, [*Timeout*], [*Options*])

Parameters

FeedUrl

A string value which specifies the URL for the news feed. To access a news feed on a web server, a standard http or https URL may be used. To access a file on the local system or network share, a file name or file URL may be specified.

Timeout

The number of seconds that the client will wait for a response before failing the operation. This parameter is ignored if the ***FeedUrl*** parameter specifies a local file name or URL.

Options

An optional numeric parameter that specifies one or more options when opening the news feed. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
rssOptionNone	No additional options are specified and the news feed is processed using relaxed rules when checking the validity of the feed. The control will attempt to automatically compensate for a feed that is malformed or does not strictly conform to the RSS standard. This is the default value if the <i>Options</i> parameter is omitted.
rssOptionStrict	The news feed content should be processed using strict rules to ensure that the feed meets the appropriate RSS standard specification and all feed property values are case-sensitive. By default, relaxed rules are used which allows the application to open a feed that may not strictly conform to the standard specification.

Return Value

A value of zero is returned if the news feed was opened successfully. Otherwise, a non-zero error code is returned which indicates the cause of the failure. If the method fails, the value of the **LastError** property can be used to determine cause of the failure.

Remarks

A news feed may be local or remote, depending on the URL that is specified. If a local file name or file URL is specified for the feed, then it is opened locally and no network access is required. If an http or https URL is specified, then the **Open** method will attempt to download the feed from the server and store it temporarily on the local system. Accessing a remote feed requires that the application has permission to establish a connection with the server and will cause the application to block until the feed has been downloaded, the operation times out or an error occurs.

Although the **Open** method will meet the needs of most applications, if you require more complex functionality such as retrieving the feed asynchronously in the background or event notifications for large transfers, you can use the SocketTools [Hypertext Transfer Protocol](#) control to download the news feed and then use the **Parse** method to parse the contents.

Example

The following example accesses a remote feed and enumerates each news item, populating the contents of a ListBox control with its title.

```
Dim strFeed As String
Dim nIndex As Long
Dim nError As Long

strFeed = "http://sockettools.com/rss/news.xml"
ListBox1.Clear

nError = NewsFeed1.Open(strFeed)
If nError > 0 Then
    MsgBox NewsFeed1.LastErrorString, vbExclamation
    Exit Sub
End If

Label1.Caption = NewsFeed1.ItemCount & " news items, published on " &
NewsFeed1.Published

For nIndex = 1 To NewsFeed1.ItemCount
    nError = NewsFeed1.GetItem(nIndex)
    If nError > 0 Then
        MsgBox NewsFeed1.LastErrorString, vbExclamation
        Exit For
    End If
    ListBox1.AddItem NewsFeed1.ItemTitle
Next
```

See Also

[Close Method](#), [GetItem Method](#), [Open Method](#), [Parse Method](#), [Store Method](#)

Parse Method

Open the specified news feed and select the first news item.

Syntax

object.Parse(*FeedXml*, [*Options*])

Parameters

FeedXml

A string value which contains the contents of the news feed to be parsed.

Options

An optional numeric parameter that specifies one or more options when opening the news feed. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
rssOptionNone	No additional options are specified and the news feed is processed using relaxed rules when checking the validity of the feed. The control will attempt to automatically compensate for a feed that is malformed or does not strictly conform to the RSS standard. This is the default value if the <i>Options</i> parameter is omitted.
rssOptionStrict	The news feed content should be processed using strict rules to ensure that the feed meets the appropriate RSS standard specification and all feed property values are case-sensitive. By default, relaxed rules are used which allows the application to open a feed that may not strictly conform to the standard specification.

Return Value

A value of zero is returned if the string contains a valid RSS feed and the contents were successfully parsed. Otherwise, a non-zero error code is returned which indicates the cause of the failure. If the method fails, the value of the **LastError** property can be used to determine cause of the failure.

Remarks

The **Parse** method is an alternative to the **Open** method, enabling the application to process a news feed from alternative sources such as a database or compressed file. It is important to note that the string which contains the news feed XML must be properly formatted and conform to the RSS standard specification.

Example

The following example opens a local file that contains a news feed, stores the contents in a string variable and parses the contents. A **ListBox** control is populated with the title of each news item in the feed. Note that this example was written to demonstrate the use of the **Parse** method, however the **Open** method can also be used to open a local file and requires less code.

```
Dim hFile As Long
Dim strFileName As String
Dim strFeedXml As String
Dim nIndex As Long
Dim nError As Long
```

```

strFileName = "newsfeed.xml"

hFile = FreeFile()
Open strFileName For Input As #hFile
strFeedXml = Input(LOF(hFile), #hFile)
Close #hFile

nError = NewsFeed1.Parse(strFeedXml)
If nError > 0 Then
    MsgBox NewsFeed1.LastErrorString, vbExclamation
    Exit Sub
End If

ListBox1.Clear
Label1.Caption = NewsFeed1.ItemCount & " news items, published on " &
NewsFeed1.Published

For nIndex = 1 To NewsFeed1.ItemCount
    nError = NewsFeed1.GetItem(nIndex)
    If nError > 0 Then
        MsgBox NewsFeed1.LastErrorString, vbExclamation
        Exit For
    End If
    ListBox1.AddItem NewsFeed1.ItemTitle
Next

```

See Also

[Close Method](#), [GetItem Method](#), [Open Method](#), [Store Method](#)

Refresh Method

Refresh the current news feed.

Syntax

object.Refresh

Parameters

None.

Return Value

A value of zero is returned if the feed was refreshed successfully. Otherwise, a non-zero error code is returned which indicates the cause of the failure. If the method fails, the value of the **LastError** property can be used to determine cause of the failure.

Remarks

When the **Refresh** method is called, the news feed is reloaded from the original source and the items in the channel are updated. For news feeds that are frequently updated, the **TimeToLive** property can provide a hint to the application as to how frequently the feed should be refreshed.

If the news feed was originally opened using an http or https URL, this function will download the updated feed from the server and store it temporarily on the local system. Accessing a remote feed requires that the application has permission to establish a connection with the server and will cause the application to block until the feed has been downloaded, the operation times out or an error occurs. The same timeout period and options will be used as when the feed was originally opened.

The **Refresh** method should only be used if the feed was opened using the **Open** method, otherwise the method will fail with an error indicating that the operation is not supported.

It is important that the application does not make any assumptions about the number of news items in the channel, or the content associated with those items after the **Refresh** method has been called. For example, never assume that the number of items in the news feed remains the same, or that the item IDs for each item remains the same. If you need to find a specific item in the news feed, use the **FindItem** method.

See Also

[TimeToLive Property](#), [FindItem Method](#), [GetItem Method](#), [Open Method](#), [Parse Method](#)

Reset Method

Reset the internal state of the control.

Syntax

object.Reset

Parameters

None.

Return Value

None.

Remarks

The **Reset** method resets the internal state of the control. Property values are initialized to their internal defaults, open network connections will be closed and any handles allocated by the control will be released.

See Also

[Initialize Method](#), [Uninitialize Method](#)

Store Method

Store the contents of the news feed in an XML formatted text file.

Syntax

object.Store(FileName, [Options])

Parameters

FileName

A string value which specifies the name of the file on the local system. The contents of the news feed will be stored in this file. If the file does not exist, it will be created; otherwise it will overwrite the contents of the file.

Options

An optional parameter reserved for future use. It should either be omitted from the method call, or passed with a value of 0.

Return Value

A value of zero is returned if the contents of the news feed has been successfully stored in the specified file. Otherwise, a non-zero error code is returned which indicates the cause of the failure. If the method fails, the value of the **LastError** property can be used to determine cause of the failure.

See Also

[Close Method](#), [GetItem Method](#), [Open Method](#), [Parse Method](#)

Uninitialize Method

Uninitialize the control and release any system resources that were allocated.

Syntax

object.Uninitialize

Parameters

None.

Return Value

None.

Remarks

The **Uninitialize** method terminates any connection established by the control and resets the internal state of the control. This method is not typically used because any resources that have been allocated by an instance of the control will automatically be released when it is destroyed.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the control will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the control was created. An application should only call the **Uninitialize** method if it has explicitly called the **Initialize** method.

See Also

[Close Method](#), [Initialize Method](#), [Reset Method](#)

News Feed Control Events

Event	Description
OnError	This event occurs when a control error occurs

OnError Event

The **OnError** event is generated when a control error occurs.

Syntax

```
Sub object_OnError ( [Index As Integer,] ByVal ErrorCode As Variant, ByVal Description As Variant )
```

Remarks

This event occurs when an error occurs during a control action. Errors not generated by the control itself, such as errors related to the programming language or general component errors, do not trigger this event.

The ***ErrorCode*** argument specifies the last error that has occurred. If the error is network related, the error code values returned by the control correspond to those returned by the standard Windows Sockets library.

The ***Description*** argument is a string that describes the error.

Network News Transfer Protocol Control

Download and submit articles to a news server.

Reference

- [Properties](#)
- [Methods](#)
- [Events](#)
- [Error Codes](#)

Control Information

Object Name	NntpClientCtl.NntpClient
File Name	CSNWSX12.OCX
Version	12.0.3024.1286
ProgID	SocketTools.NntpClient.12
ClassID	DEC81A71-4F58-4E03-B601-E486822DBD1F
Threading Model	Apartment
Help File	CST12CTL.CHM
Dependencies	None
Standards	RFC 977, RFC 2980

Overview

The Network News Transfer Protocol (NNTP) is used with servers that provide news services. This is similar in functionality to bulletin boards or message boards, where topics are organized hierarchically into groups, called newsgroups. Users can browse and search for messages, called news articles, which have been posted by other users. On many servers, they can also post their own articles which can be read by others. The largest collection of public newsgroups available is called USENET, a world-wide distributed discussion system. In addition, there are a large number of smaller news servers. For example, Microsoft operates a news server which functions as a forum for technical questions and announcements.

The control provides a comprehensive interface for accessing newsgroups, retrieving articles and posting new articles. In combination with the Mail Message control to process the news articles, SocketTools can be used to integrate newsgroup access with an existing email application, or you can implement your own full-featured newsgroup client.

The control supports secure explicit and implicit connections using TLS 1.2 or later with client certificates for authentication. By simply setting a few properties, a secure connection using 256-bit AES encryption can be established, providing your application with the highest level of security available.

Requirements

The SocketTools ActiveX Edition components are self-registering controls that are compatible with any programming language that supports the Component Object Model (COM) and the ActiveX control specification. If you are using Visual Basic 6.0, Service Pack 6 (SP6) is required. We recommend

installing all available updates for your development tools. Although the Visual Basic 6.0 runtime is supported on Windows 11, the IDE itself is no longer officially supported by Microsoft. Legacy IDEs and compilers may also require elevated (administrator) privileges to run properly.

The ActiveX controls are supported on Windows 7, Windows Server 2008 R2, and later versions of both desktop and server editions of Windows. For Windows 7, Service Pack 1 (SP1) is the minimum requirement. For Windows 8 systems, the 8.1 update must be installed. On ARM-based platforms, the minimum supported version is Windows 10 build 1709.

SocketTools includes components for both 32-bit (x86) and 64-bit (x64) Windows platforms. All modern versions of Windows are 64-bit, but we continue to include 32-bit components for compatibility with legacy development tools such as Visual Basic 6.0. We also provide native ARM64 ActiveX controls for systems running Windows on ARM. Note that 32-bit applications on ARM run using x86 emulation, and Microsoft no longer supports native ARM32 applications.

If you are using VBScript, Visual Basic for Applications (VBA), or another scripting environment on an ARM-based system, be aware that 64-bit hosts will require ARM64 components, while 32-bit hosts will use x86 components under emulation. This includes applications created with Visual Basic 6.0. To reduce deployment complexity and avoid confusion, SocketTools does not include ARM32 ActiveX controls in its standard redistribution packages but they are available on request for legacy or specialized scenarios.

Distribution

When you distribute an application that uses this control, you can either install the file in the same folder as your application executable or as a shared component in the appropriate system folder. If you install the control in the system folder, it is important that you distribute the correct version for the target platform and it must be registered. If you install the control in the same folder as your executable, it is recommended that you use registration-free activation or COM redirection to ensure that the correct version of the control is loaded by the application.

Network News Transfer Protocol Control Properties

Property	Description
Article	Gets and sets the current article number
ArticleCount	Return the number of available articles
AutoResolve	Determines if host names and IP addresses are automatically resolved
Blocking	Gets and sets the blocking state of the control
CertificateExpires	Return the date and time that the server certificate expires
CertificateIssued	Return the date and time that the server certificate was issued
CertificateIssuer	Returns information about the organization that issued the server certificate
CertificateName	Gets and sets the common name for the client certificate
CertificatePassword	Gets and sets the password associated with the client certificate
CertificateStatus	Return the status of the server certificate
CertificateStore	Gets and sets the name of the client certificate store or file
CertificateSubject	Returns information about the organization to which the server certificate was issued
CertificateUser	Gets and sets the user that owns the client certificate
CipherStrength	Return the length of the key used by the encryption algorithm
CurrentDate	Return the current date in the standard format used by news articles
FirstArticle	Return the first available article number
GroupCount	Return the number of available groups
GroupName	Gets and sets the current newsgroup name
GroupTitle	Return a string describing the current newsgroup
HashStrength	Return the length of the message digest that was selected
HostAddress	Gets and sets the IP address of the server
HostName	Gets and sets the name of the server
IsBlocked	Return if the control is blocked performing an operation
IsConnected	Determine if the control is connected to a server
IsInitialized	Determine if the control has been initialized
IsReadable	Return if data can be read from the server without blocking
IsWritable	Return if data can be sent to the server without blocking
LastArticle	Return the last available article number
LastError	Gets and sets the last error that occurred on the control
LastErrorString	Return a description of the last error to occur
LastUpdate	Gets and sets the date the newsgroup list was last updated
MessageId	Gets and sets the current article by message ID
Options	Gets and sets the options that are used in establishing a connection

Password	Gets and sets the password for the current user
RemotePort	Gets and sets the port number for a remote connection
ResultCode	Return the result code of the previous action
ResultString	Return a string describing the results of the previous action
Secure	Set or return if a connection to the server is secure
SecureCipher	Return the encryption algorithm used to establish the secure connection with the server
SecureHash	Return the message digest selected when establishing the secure connection with the server
SecureKeyExchange	Return the key exchange algorithm used to establish the secure connection with the server
SecureProtocol	Gets and sets the security protocol used to establish the secure connection with the server
ThrowError	Enables or disables error handling by the application
Timeout	Gets and sets the amount of time until a blocking operation fails
Trace	Enable or disable socket function level tracing
TraceFile	Specify the socket function trace output file
TraceFlags	Gets and sets the socket function tracing flags
UserName	Gets and sets the current user name
Version	Return the current version of the control

Article Property

Gets and sets the current article number.

Syntax

object.Article [= *number*]

Remarks

The Article property sets or returns the current news article number. Setting the Article property updates the MessageId property to reflect the specified article's message ID.

Data Type

Integer (Int32)

See Also

[ArticleCount Property](#), [FirstArticle Property](#), [LastArticle Property](#), [MessageId Property](#)

ArticleCount Property

Return the number of available articles in the current newsgroup.

Syntax

object.**ArticleCount**

Remarks

The **ArticleCount** property returns the number of articles that are available in the current newsgroup. Note that this is a read-only property available at run-time. This value is only meaningful after the **SelectGroup** method has been called.

Data Type

Integer (Int32)

See Also

[Article Property](#), [FirstArticle Property](#), [LastArticle Property](#), [ListArticles Method](#), [SelectGroup Method](#)

AutoResolve Property

Determines if host names and IP addresses are automatically resolved.

Syntax

object.AutoResolve [= { True | False }]

Remarks

Setting the **AutoResolve** property determines if the control automatically resolves host names and addresses specified by the **HostName** and **HostAddress** properties. If set to True, setting the **HostName** property will cause the control to automatically determine the corresponding IP address and set the **HostAddress** property accordingly. Likewise, setting the **HostAddress** property will cause the control to determine the host name and set the **HostName** property. Setting the property to False prevents the control from resolving host names until a connection attempt is made.

Note that setting the **HostName** or **HostAddress** property may cause the current thread to block, sometimes for several seconds, until the name or address is resolved. To prevent this behavior, set **AutoResolve** to False.

Data Type

Boolean

See Also

[HostAddress Property](#), [HostName Property](#)

Blocking Property

Gets and sets the blocking state of the control.

Syntax

object.**Blocking** [= { True | False }]

Remarks

Setting the **Blocking** property determines if control actions complete synchronously or asynchronously. If set to True, then each control action, such as sending or receiving data, will return when the operation has completed or timed-out. If set to False, control actions will return immediately. If the operation would result in the control blocking, such as attempting to read data when none has been written, an error is generated. Events such as **OnConnect**, **OnDisconnect**, **OnRead** and **OnWrite** are only fired if the connection is non-blocking.

Data Type

Boolean

See Also

[IsBlocked Property](#), [IsReadable Property](#), [IsWritable Property](#)

CertificateExpires Property

Return the date and time that the server certificate expires.

Syntax

object.CertificateExpires

Remarks

The **CertificateExpires** property returns the date and time that the server certificate expires. This property will return an empty string if a secure connection has not been established with the server.

Data Type

String

See Also

[CertificateIssued Property](#), [CertificateIssuer Property](#), [CertificateStatus Property](#), [CertificateSubject Property](#), [Secure Property](#)

CertificateIssued Property

Return the date and time that the server certificate was issued.

Syntax

object.CertificateIssued

Remarks

The **CertificateIssued** property returns the date and time that the server certificate was issued. This property will return an empty string if a secure connection has not been established with the server.

Data Type

String

See Also

[CertificateExpires Property](#), [CertificateIssuer Property](#), [CertificateStatus Property](#), [CertificateSubject Property](#), [Secure Property](#)

CertificateIssuer Property

Returns information about the organization that issued the server certificate.

Syntax

object.CertificateIssuer

Remarks

The **CertificateIssuer** property returns a string that contains information about the organization that issued the server certificate. The string value is a comma separated list of tagged name and value pairs. In the nomenclature of the X.500 standard, each of these pairs are called a relative distinguished name (RDN), and when concatenated together, forms the issuer's distinguished name (DN). For example:

C=US, O="RSA Data Security, Inc.", OU=Secure Server Certification Authority

To obtain a specific value, such as the name of the issuer or the issuer's country, the application must parse the string returned by this property. Some of the common tokens used in the distinguished name are:

Name	Description
C	The ISO standard two character country code
S	The name of the state or province
L	The name of the city or locality
O	The name of the company or organization
OU	The name of the department or organizational unit
CN	The common name; with X.509 certificates, this is the domain name of the site the certificate was issued for

This property will return an empty string if a secure connection has not been established with the server.

Data Type

String

Example

The following example demonstrates how to extract the value of a relative distinguished name token:

```
Function GetCertNameValue(ByVal strValue As String, ByVal strFieldName As String)
As String
    Dim strFieldValue As String
    Dim cchValue As Integer, cchFieldName As Integer
    Dim nOffset As Integer

    GetCertNameValue = ""
    cchValue = Len(strValue)
    cchFieldName = Len(strFieldName)

    If cchValue = 0 Or cchFieldName = 0 Then
        Exit Function
    End If
```

```

nOffset = InStr(strValue, strFieldName & "=")

If nOffset > 0 Then
    '
    ' If the field name was found in the string, then
    ' remove everything to the left of the token from
    ' the string
    '
    strFieldValue = Right(strValue, cchValue - (nOffset + cchFieldName))

    '
    ' If the value is quoted, then strip off the leading
    ' quote and look for the ending quote in the string;
    ' otherwise look for the comma that marks the end of
    ' the field name/value pair
    '
    If Left(strFieldValue, 1) = Chr(34) Then
        strFieldValue = Right(strFieldValue, Len(strFieldValue) - 1)
        nOffset = InStr(strFieldValue, Chr(34))
    Else
        nOffset = InStr(strFieldValue, ",")
    End If

    '
    ' If the offset is 0, then the name/value pair is
    ' the last token in the string; otherwise, remove
    ' everything to the right of that position
    '

    If nOffset > 0 Then
        strFieldValue = Left(strFieldValue, nOffset - 1)
    End If

    GetCertNameValue = strFieldValue
End If

```

End Function

This function could then be used to return the name of the company who issued the server certificate:

```

Dim strIssuer As String
Dim strCompanyName As String

strIssuer = NntpClient1.CertificateIssuer
If Len(strIssuer) = 0 Then
    MsgBox "A secure connection has not been established"
Else
    strCompanyName = GetCertNameValue(strIssuer, "O")
    MsgBox "This certificate was issued by " & strCompanyName
End If

```

See Also

[CertificateExpires Property](#), [CertificateIssued Property](#), [CertificateStatus Property](#), [CertificateSubject Property](#), [Secure Property](#)

CertificateName Property

Gets and sets the common name for the client certificate.

Syntax

object.CertificateName [= *name*]

Remarks

This property sets the common name or friendly name of the certificate that should be used to establish the connection with the server. It is only required that you set this property value if the server requires a client certificate for authentication. If this property is not set, a client certificate will not be provided to the server. If a certificate name is specified, the certificate must have a private key associated with it, otherwise the connection attempt will fail because the control will be unable to create a security context for the session.

Certificates may be installed and viewed on the local system using the Certificate Manager that is included with the Windows operating system. For more information, refer to the documentation for the Microsoft Management Console.

Data Type

String

See Also

[CertificateStore Property](#), [Secure Property](#)

CertificatePassword Property

Gets and sets the password associated with the client certificate.

Syntax

object.CertificatePassword [= *password*]

Remarks

This property sets the password that should be used to access a certificate in the specified certificate store. It is only required when the **CertificateStore** property specifies a file that contains a certificate and private key in PKCS #12 format.

Data Type

String

See Also

[CertificateName Property](#), [CertificateStore Property](#), [Secure Property](#)

CertificateStatus Property

Return the status of the server certificate.

Syntax

`object.CertificateStatus`

Remarks

The **CertificateStatus** property returns an integer value which identifies the status of the server certificate. This property may return one of the following values:

Value	Description
stCertificateNone	No certificate information is available. A secure connection was not established with the server.
stCertificateValid	The certificate is valid.
stCertificateNoMatch	The certificate is valid, however the domain name specified in the certificate does not match the domain name of the site that the client has connected to. This is typically the case if the HostAddress property is used rather than the HostName property. It is recommended that the client examine the CertificateSubject property to determine the domain name of the site that the certificate was issued for.
stCertificateExpired	The certificate has expired and is no longer valid. The client can examine the CertificateExpires property to determine when the certificate expired.
stCertificateRevoked	The certificate has been revoked and is no longer valid. It is recommended that the client application immediately terminate the connection if this status is returned.
stCertificateUntrusted	The certificate has not been issued by a trusted authority, or the certificate is not trusted on the local host. It is recommended that the client application immediately terminate the connection if this status is returned.
stCertificateInvalid	The certificate is invalid. This typically indicates that the internal structure of the certificate is damaged. It is recommended that the client application immediately terminate the connection if this status is returned.

This property value should be checked after the connection to the server has completed, but prior to beginning a transaction. If a secure connection has not been established, this property will return a value of zero.

Data Type

Integer (Int32)

Example

The following example establishes a secure connection to a server:

,

```

' Initialize the control properties
,

NntpClient1.HostName = strHostName
NntpClient1.Secure = True

nError = NntpClient1.Connect()
If nError > 0 Then
    MsgBox "Unable to connect to server " & strHostName, vbExclamation
    Exit Sub
End If

If NntpClient1.CertificateStatus <> stCertificateValid Then
    nResult = MsgBox("The server certificate could not be validated" & vbCrLf & _
        "Are you sure you wish to continue?", vbYesNo)

    If nResult = vbNo Then
        NntpClient1.Disconnect
        Exit Sub
    End If
End If

NntpClient1.Disconnect

```

See Also

[CertificateExpires Property](#), [CertificateIssued Property](#), [CertificateIssuer Property](#), [CertificateSubject Property](#), [Secure Property](#)

CertificateStore Property

Gets and sets the name of the client certificate store or file.

Syntax

object.CertificateStore [= *store*]

Remarks

This property sets the name of the certificate store that contains the client certificate that should be used when establishing a secure connection with the server. The certificate may either be stored in the registry or in a file. If the certificate is stored in the registry, then this property should be set to one of the following predefined values:

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. If a certificate store is not specified, this is the default value that is used.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

In most cases the client certificate will be installed in the user's personal certificate store, and therefore it is not necessary to set this property value because that is the default location that will be used to search for the certificate. This property is only used if the **CertificateName** property is also set to a valid certificate name.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU" for the current user, or "HKLM" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, it will default to the certificate store for the current user.

This property may also be used to specify a file that contains the client certificate. In this case, the property should specify the full path to the file and must contain both the certificate and private key in PKCS #12 format. If the file is protected by a password, the **CertificatePassword** property must also be set to specify the password.

Data Type

String

See Also

[CertificateName Property](#), [CertificatePassword Property](#), [Secure Property](#)

CertificateSubject Property

Returns information about the organization that the server certificate was issued to.

Syntax

`object.CertificateSubject`

Remarks

The **CertificateSubject** property returns a string that contains information about the organization that the server certificate was issued for. The string value is a comma separated list of tagged name and value pairs. In the nomenclature of the X.500 standard, each of these pairs are called a relative distinguished name (RDN), and when concatenated together, forms the subject's distinguished name (DN). For example:

C=US, O="RSA Data Security, Inc.", OU=Secure Server Certification Authority

To obtain a specific value, such as the name of the subject's company or country, the application must parse the string returned by this property. Some of the common tokens used in the distinguished name are:

Name	Description
C	The ISO standard two character country code
S	The name of the state or province
L	The name of the city or locality
O	The name of the company or organization
OU	The name of the department or organizational unit
CN	The common name; with X.509 certificates, this is the domain name of the site the certificate was issued for

This property will return an empty string if a secure connection has not been established with the server.

Data Type

String

Example

The following example demonstrates how to extract the value of a relative distinguished name token:

```
Function GetCertNameValue(ByVal strValue As String, ByVal strFieldName As String)
As String
    Dim strFieldValue As String
    Dim cchValue As Integer, cchFieldName As Integer
    Dim nOffset As Integer

    GetCertNameValue = ""
    cchValue = Len(strValue)
    cchFieldName = Len(strFieldName)

    If cchValue = 0 Or cchFieldName = 0 Then
        Exit Function
    End If
```

```

nOffset = InStr(strValue, strFieldName & "=")

If nOffset > 0 Then
    '
    ' If the field name was found in the string, then
    ' remove everything to the left of the token from
    ' the string
    '
    strFieldValue = Right(strValue, cchValue - (nOffset + cchFieldName))

    '
    ' If the value is quoted, then strip off the leading
    ' quote and look for the ending quote in the string;
    ' otherwise look for the comma that marks the end of
    ' the field name/value pair
    '
    If Left(strFieldValue, 1) = Chr(34) Then
        strFieldValue = Right(strFieldValue, Len(strFieldValue) - 1)
        nOffset = InStr(strFieldValue, Chr(34))
    Else
        nOffset = InStr(strFieldValue, ",")
    End If

    '
    ' If the offset is 0, then the name/value pair is
    ' the last token in the string; otherwise, remove
    ' everything to the right of that position
    '
    If nOffset > 0 Then
        strFieldValue = Left(strFieldValue, nOffset - 1)
    End If

    GetCertNameValue = strFieldValue
End If

```

End Function

This function could then be used to return the domain name that the server certificate was issued for:

```

Dim strSubject As String
Dim strDomainName As String

strSubject = NntpClient1.CertificateSubject
If Len(strSubject) = 0 Then
    MsgBox "A secure connection has not been established"
Else
    strDomainName = GetCertNameValue(strSubject, "CN")
    MsgBox "This certificate was issued for " & strDomainName
End If

```

See Also

[CertificateExpires Property](#), [CertificateIssued Property](#), [CertificateIssuer Property](#), [CertificateStatus Property](#), [Secure Property](#)

CertificateUser Property

Gets and sets the user that owns the client certificate.

Syntax

object.CertificateUser [= *username*]

Remarks

This property sets the name of the user that owns the client certificate that will be used to establish a secure connection with the server. If this property is not set, the certificate store for the current user will be used when searching for the certificate. If this property is used to specify another user, the process must have the appropriate permission to access the registry location that contains the client certificate. On Windows Vista and later versions of the operating system, this requires that the process run with elevated privileges.

Data Type

String

See Also

[CertificateName Property](#), [CertificateStore Property](#), [Secure Property](#)

CipherStrength Property

Return the length of the key used by the encryption algorithm.

Syntax

object.CipherStrength

Remarks

The **CipherStrength** property returns the number of bits in the key used to encrypt the secure data stream. Common values returned by this property are 128 and 256. A key length of 40-bits or 56-bits is considered to be insecure, and subject to brute force attacks. 128-bit and 256-bit keys are considered secure. If this property returns a value of 0, this means that a secure connection has not been established with the server.

Data Type

Integer (Int32)

See Also

[HashStrength Property](#), [Secure Property](#), [SecureCipher Property](#), [SecureHash Property](#), [SecureKeyExchange Property](#), [SecureProtocol Property](#)

CurrentDate Property

Return the current date in the standard format used by news articles.

Syntax

object.CurrentDate

Remarks

The **CurrentDate** property returns the current date and time in a format that is commonly used in news articles.

Data Type

String

FirstArticle Property

Return the first available article number.

Syntax

object.FirstArticle

Remarks

The **FirstArticle** property returns the first article number available in the current newsgroup. Note that this is a read-only property available at run-time.

Data Type

Integer (Int32)

See Also

[Article Property](#), [ArticleCount Property](#), [LastArticle Property](#)

GroupCount Property

Return the number of available groups.

Syntax

object.GroupCount

Remarks

The **GroupCount** property returns the number of newsgroups that have been returned by the server. Note that this is a read-only property available at run-time and the value is only meaningful after the **ListGroups** method has been called.

Data Type

Integer (Int32)

See Also

[GroupName Property](#), [GroupTitle Property](#), [ListGroups Method](#)

GroupName Property

Gets and sets the current newsgroup name.

Syntax

object.GroupName [= *group*]

Remarks

The **GroupName** property sets or returns the current newsgroup. Setting this property causes the related properties, such as **FirstArticle** and **LastArticle**, to be updated.

Data Type

String

See Also

[GroupCount Property](#), [GroupTitle Property](#)

GroupTitle Property

Return a string describing the current newsgroup.

Syntax

object.GroupTitle

Remarks

The **GroupTitle** property returns a string describing the current newsgroup. This property is read-only and available only at run-time.

Data Type

String

See Also

[GroupCount Property](#), [GroupName Property](#)

HashStrength Property

Return the length of the message digest that was selected.

Syntax

object.HashStrength

Remarks

The **HashStrength** property returns the number of bits used in the message digest (hash) that was selected. Common values returned by this property are 128 and 160. If this property returns a value of 0, this means that a secure connection has not been established with the server.

Data Type

Integer (Int32)

See Also

[CipherStrength Property](#), [Secure Property](#), [SecureCipher Property](#), [SecureHash Property](#), [SecureKeyExchange Property](#), [SecureProtocol Property](#)

HostAddress Property

Gets and sets the IP address of the server.

Syntax

object.HostAddress [= *ipaddress*]

Remarks

The **HostAddress** property can be used to set the IP address for a server that you wish to communicate with. If the address is valid and matches an entry in the host table, the **HostName** property will be changed to match the address.

Data Type

String

See Also

[AutoResolve Property](#), [HostName Property](#)

HostName Property

Gets and sets the name of the server.

Syntax

object.HostName [= *hostname*]

Remarks

The **HostName** property should be set to the name of the server that you wish to communicate with. If the name is found in the host table, the **HostAddress** property is updated to reflect the IP address of the host.

Note that it is legal to assign an IP address to this property, but it is not legal to assign a host name to the **HostAddress** property.

Data Type

String

See Also

[AutoResolve Property](#), [HostAddress Property](#)

IsBlocked Property

Return if the control is blocked performing an operation.

Syntax

object.IsBlocked

Remarks

The **IsBlocked** property returns True if the specified control is blocked performing an operation. Because the Windows Sockets API only permits one blocking operation per thread of execution, this property should be checked before starting any blocking operation.

Note that this property will return True if there is *any* blocking operation being performed by the application, regardless if the specified control is responsible for the blocking operation or not.

Data Type

Boolean

See Also

[Blocking Property](#), [LastError Property](#)

IsConnected Property

Determine if the control is connected to a server.

Syntax

object.**IsConnected**

Remarks

The **IsConnected** read-only property is set to a value of true if the control is connected with a server, otherwise the property has a value of false.

Data Type

Boolean

IsInitialized Property

Determine if the control has been initialized.

Syntax

object.IsInitialized

Remarks

The **IsInitialized** property is used to determine if the current instance of the control has been initialized properly. Normally this is done automatically when the control is loaded, however there are circumstances where the control may not be able to initialize itself. If this property returns **False**, the application must call the **Initialize** method to initialize the control before performing any other operation.

The most common reason that the control may not initialize correctly is that no valid development or runtime license key can be found or the license key that was provided is invalid. It may also indicate a problem with the system configuration or user access rights, such as not being able to load the required networking libraries or not being able to access the system registry.

Data Type

Boolean

See Also

[Initialize Method](#)

IsReadable Property

Return if data can be read from the server without blocking.

Syntax

object.IsReadable

Remarks

The **IsReadable** property returns True if data can be read from the server without blocking. For non-blocking connections, this property can be checked before the application attempts to read the data, preventing an error.

Data Type

Boolean

See Also

[IsConnected Property](#), [Read Method](#), [OnRead Event](#)

IsWritable Property

Return if data can be sent to the server without blocking.

Syntax

object.IsWritable

Remarks

The **IsWritable** property returns True if data can be written without blocking. For non-blocking connections, this property can be checked before the application attempts to send data to the server, preventing an error.

If the **IsWritable** property returns False, this means that the application cannot write to the socket at that time. However, if the property returns True, this does not guarantee that you will be able to send data without an error. The next operation may result in an **stErrorOperationWouldBlock** or **stErrorOperationInProgress** error. The application must treat these errors as recoverable, and should be prepared to retry operations that result in them.

Data Type

Boolean

See Also

[IsReadable Property](#), [Write Method](#), [OnWrite Event](#)

LastArticle Property

Return the last available article number.

Syntax

object.LastArticle

Remarks

The **LastArticle** property returns the last article number available in the current newsgroup. Note that this is a read-only property available at run-time.

Data Type

Integer (Int32)

See Also

[Article Property](#), [ArticleCount Property](#), [FirstArticle Property](#)

LastError Property

Gets and sets the last error that occurred on the control.

Syntax

object.LastError [= *value*]

Remarks

The **LastError** property can be read to determine the last error that occurred for this control. If a value is assigned to this property, it must either be zero to clear the error or a valid error code for the control.

Data Type

Integer (Int32)

See Also

[LastErrorString Property](#), [OnError Event](#)

LastErrorString Property

Return a description of the last error to occur.

Syntax

object.LastErrorString

Remarks

The **LastErrorString** property returns a description of the last error that occurred. This can be used to display a meaningful error message to a user, rather than just the numeric value returned by the **LastError** property.

Data Type

String

See Also

[LastError Property](#), [OnError Event](#)

LastUpdate Property

Gets and sets the date the newsgroup list was last updated.

Syntax

object.LastUpdate [= *date*]

Remarks

The **LastUpdate** property is used to specify the last date and time that a list of newsgroups was retrieved from the server. When this property is set, only those newsgroups created after that date will be returned when the server is asked for a list of groups. If this property is set to an empty string, then the server will return all groups, regardless of when they were created.

This property should be used by client applications to reduce the amount of time needed to update the list of available newsgroups, particularly if the server offers a large number of newsgroups. For example, the first time that the client connects to the server, the **LastUpdate** property should not be set. That will cause the server to return a list of all of the newsgroups that it has available. The client should then store that list on the local system in a file, and record the date and time that it created the list. Then, the next time that the client connects to the server, it should set the **LastUpdate** property to the date that the local list of newsgroups was last updated. When the list of newsgroups is requested again, the server will only return those newsgroups that were created since the last time the list was updated rather than the complete list.

Data Type

String

See Also

[GetFirstGroup Method](#), [GetNextGroup Method](#), [ListGroups Method](#), [OnNewsGroup Event](#)

MessageID Property

Gets and sets the current article by message ID.

Syntax

object.MessageId [= *number*]

Remarks

The **MessageId** property sets or returns the current message ID string. Each news article has a unique string which identifies that message. Setting the **MessageId** property causes the current article number to change to the given message. An error is generated if the property is set to an invalid message ID.

Data Type

String

See Also

[Article Property](#), [ArticleCount Property](#), [FirstArticle Property](#), [LastArticle Property](#)

Options Property

Gets and sets the options that are used in establishing a connection.

Syntax

object.Options [= *value*]

Remarks

The **Options** property is an integer value which specifies one or more options. The value specified for this property will be used as the default options when connecting to the server. The property value is created by using a bitwise operator with one or more of the following values:

Value	Description
nntpOptionNone	No additional options are specified when establishing a connection with the server. A standard, non-secure connection will be used.
nntpOptionTunnel	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
nntpOptionTrustedSite	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
nntpOptionSecure	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using the TLS protocol.
nntpOptionSecureFallback	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
nntpOptionPreferIPv6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.

Data Type

Integer (Int32)

See Also

[Secure Property](#), [Connect Method](#)

Password Property

Gets and sets the password for the current user.

Syntax

object.Password [= *password*]

Remarks

The **Password** property specifies the password used to authenticate the user. If a password is not required by the server, this property is ignored.

Data Type

String

See Also

[UserName Property](#), [Authenticate Method](#)

RemotePort Property

Gets and sets the port number for a remote connection.

Syntax

object.RemotePort [= *portnumber*]

Remarks

The **RemotePort** property is used to set the port number that the control will use to establish a connection with the server.

Data Type

Integer (Int32)

See Also

[HostAddress Property](#), [HostName Property](#)

ResultCode Property

Return the result code of the previous action.

Syntax

object.ResultCode

Remarks

The **ResultCode** read-only property returns the result code of the last action performed by the client. This property should be checked after the **Command** method is used to execute a command on the server to determine if the operation was successful. Result codes are three-digit numeric values returned by the server and may be broken down into the following ranges:

Value	Description
100-199	Positive preliminary result. This indicates that the requested action is being initiated, and the client should expect another reply from the server before proceeding.
200-299	Positive completion result. This indicates that the server has successfully completed the requested action.
300-399	Positive intermediate result. This indicates that the requested action cannot complete until additional information is provided to the server.
400-499	Transient negative completion result. This indicates that the requested action did not take place, but the error condition is temporary and may be attempted again.
500-599	Permanent negative completion result. This indicates that the requested action did not take place.

It is important to note that while some result codes have become standardized, not all servers respond to commands using the same result codes. For example, one server may respond with a result code of 221 to indicate success, while another may respond with a value of 235. It is recommended that applications check for ranges of values to determine if a command was successful, not a specific value.

Data Type

Integer (Int32)

See Also

[ResultString Property](#), [Command Method](#), [OnCommand Event](#)

ResultString Property

Return a string describing the results of the previous action.

Syntax

object.ResultString

Remarks

The **ResultString** read-only property returns the result string from the last action taken by the client. This string is generated by the server, and typically is used to describe the result code. For example, if an error is indicated by the result code, the result string may describe the condition that caused the error.

Data Type

String

See Also

[ResultCode Property](#), [Command Method](#), [OnCommand Event](#)

Secure Property

Set or return if a connection to the server is secure.

Syntax

object.Secure [= { True | False }]

Remarks

The **Secure** property determines if a secure connection is established to the server. The default value for this property is False, which specifies that a standard connection to the server is used. To establish a secure connection, the application must set this property value to True prior to calling the **Connect** method. Once the connection has been established, the client may request files or submit queries to the server as with standard connections.

It is strongly recommended that any application that sets this property True use error handling to trap an errors that may occur. If the control is unable to initialize the security libraries, or otherwise cannot create a secure session for the client, an error will be generated when this property value is set.

Data Type

Boolean

Example

The following example establishes a secure connection to a server:

```
NntpClient1.HostName = strHostName
NntpClient1.UserName = strUserName
NntpClient1.Password = strPassword
NntpClient1.Secure = True

nError = NntpClient1.Connect()
If nError > 0 Then
    MsgBox "Unable to connect to server " & strHostName, vbExclamation
    Exit Sub
End If

If NntpClient1.CertificateStatus <> stCertificateValid Then
    nResult = MsgBox("The server certificate could not be validated" & vbCrLf & _
        "Are you sure you wish to continue?", vbYesNo)

    If nResult = vbNo Then
        NntpClient1.Disconnect
        Exit Sub
    End If
End If
```

See Also

[CertificateStatus Property](#), [Connect Method](#)

SecureCipher Property

Return the encryption algorithm used to establish the secure connection with the server.

Syntax

object.SecureCipher

Remarks

The **SecureCipher** property returns an integer value which identifies the algorithm used to encrypt the data stream. This property may return one of the following values:

Value	Description
stCipherNone	No cipher has been selected. This is not a secure connection with the server.
stCipherRC2	The RC2 block cipher was selected. This is a variable key length cipher which supports keys between 40- and 128-bits in length, in 8-bit increments.
stCipherRC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40- and 128-bits in length, in 8-bit increments.
stCipherRC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.
stCipherDES	The DES (Data Encryption Standard) block cipher was selected. This is a fixed key length cipher using 56-bit keys.
stCipherDES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively using a 168-bit key length.
stCipherDESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.
stCipherAES	The Advanced Encryption Standard cipher (also known as the Rijndael cipher) is a fixed block size cipher which use a key size of 128, 192 or 256 bits. This cipher is supported on Windows XP SP3 and later versions of the operating system.
stCipherSkipjack	The Skipjack block cipher was selected. This is a fixed key length cipher, using 80-bit keys.
stCipherBlowfish	The Blowfish block cipher was selected. This is a variable key length cipher up to 448 bits, using a 64-bit block size.

If a secure connection has not been established, this property will return a value of zero.

Data Type

Integer (Int32)

See Also

[CipherStrength Property](#), [HashStrength Property](#), [Secure Property](#), [SecureHash Property](#), [SecureKeyExchange Property](#), [SecureProtocol Property](#)

SecureHash Property

Return the message digest selected when establishing the secure connection with the server.

Syntax

object.SecureHash

Remarks

The **SecureHash** property returns an integer value which identifies the message digest algorithm that was selected when a secure connection is established. This property may return one of the following values:

Value	Description
stHashMD5	The MD5 algorithm was selected. This algorithm has been deprecated and is no longer considered to be cryptographically secure.
stHashSHA1	The SHA-1 algorithm was selected. This algorithm has been deprecated and is no longer considered to be cryptographically secure.
stHashSHA256	The SHA-256 algorithm has been selected.
stHashSHA384	The SHA-384 algorithm has been selected.
stHashSHA512	The SHA-512 algorithm has been selected.

If a secure connection has not been established, this property will return a value of zero.

Data Type

Integer (Int32)

See Also

[CipherStrength Property](#), [HashStrength Property](#), [Secure Property](#), [SecureCipher Property](#), [SecureKeyExchange Property](#), [SecureProtocol Property](#)

SecureKeyExchange Property

Return the key exchange algorithm used to establish the secure connection with the server.

Syntax

object.SecureKeyExchange

Remarks

The **SecureKeyExchange** property returns an integer value which identifies the key-exchange algorithm used when establishing a secure connection. This property may return one of the following values:

Value	Description
stKeyExchangeNone	No key exchange algorithm has been selected. This is not a secure connection with the server.
stKeyExchangeRSA	The RSA public key exchange algorithm has been selected.
stKeyExchangeKEA	The KEA public key exchange algorithm has been selected. This is an improved version of the Diffie-Hellman public key algorithm.
stKeyExchangeDH	The Diffie-Hellman public key exchange algorithm has been selected.
stKeyExchangeECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography. This key exchange algorithm is only supported on Windows XP SP3 and later versions of the operating system.

If a secure connection has not been established, this property will return a value of zero.

Data Type

Integer (Int32)

See Also

[CipherStrength Property](#), [HashStrength Property](#), [Secure Property](#), [SecureCipher Property](#), [SecureHash Property](#), [SecureProtocol Property](#)

SecureProtocol Property

Gets and sets the security protocol used to establish the secure connection with the server.

Syntax

object.SecureProtocol [= *protocol*]

Remarks

The **SecureProtocol** property can be used to specify the security protocol to be used when establishing a secure connection with a server. By default, the control will attempt to use TLS 1.3 to establish the connection. If TLS 1.3 is not supported, TLS 1.2 will be used. The appropriate protocol is automatically selected based on the capabilities of both the client and server.

It is recommended that you only change this property value if you fully understand the implications of doing so. Assigning a value to this property will override the default and force the control to attempt to use only the protocol specified. One or more of the following values may be used:

Value	Description
stProtocolNone	No security protocol has been selected. A secure connection has not been established.
stProtocolTLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
stProtocolTLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
stProtocolTLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
stProtocolTLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

Multiple security protocols may be specified by combining them using a bitwise Or operator. After a connection has been established, reading this property will identify the protocol that was selected to establish the connection. Attempting to set this property after a connection has been established will result in an exception being thrown. This property should only be set after setting the **Secure** property to True and before calling the **Connect** method.

Data Type

Integer (Int32)

See Also

[CipherStrength Property](#), [HashStrength Property](#), [Secure Property](#), [SecureCipher Property](#), [SecureHash Property](#), [SecureKeyExchange Property](#)

ThrowError Property

Enables or disables error handling by the application.

Syntax

object.ThrowError = { True | False }

Remarks

Error handling for methods can be performed using either return codes or exceptions, depending on the value of this property.

If the **ThrowError** property is set to False, methods will return a status value indicating success or failure. Applications should check the return value of each method and use the **LastError** and **LastErrorString** properties to determine the cause of any error.

If the **ThrowError** property is set to True, errors occurring within the control will be raised to the host application as ActiveX exceptions. In addition, the **OnError** event will fire. This allows applications to use language-specific exception handling mechanisms, such as Visual Basic error handling, instead of checking individual return values after each method call.

Even when the **ThrowError** property is set to True, the **LastError** and **LastErrorString** properties will still be updated with information about the most recent error.

If an error occurs while accessing a property value, an exception will be raised regardless of the value of the **ThrowError** property. However, the **OnError** event will not be fired for property access errors.

Data Type

Boolean

Example

The following example handles errors by checking the return code of a method:

```
NntpClient1.ThrowError = False
nError = NntpClient1.Connect(strHostName)

If nError > 0 Then
    MsgBox NntpClient1.LastErrorString, vbExclamation
    Exit Sub
End If
```

The following example handles errors by throwing them to the container:

```
On Error Resume Next: Err.Clear

NntpClient1.ThrowError = True
NntpClient1.Connect strHostName

If Err.Number <> 0
    MsgBox Err.Description, vbExclamation
    Exit Sub
End If
On Error GoTo 0
```

See Also

[LastError Property](#), [LastErrorString Property](#), [OnError Event](#)

Timeout Property

Gets and sets the amount of time until a blocking operation fails.

Syntax

object.**Timeout** [= *seconds*]

Remarks

Setting the **Timeout** property specifies the number of seconds until a blocking operation fails and the control returns an error.

Note that the **Timeout** property also determines the amount of time the control will spend attempting to connect to a server. If a connection is not established within the given time period, the connection attempt will fail.

Data Type

Integer (Int32)

Trace Property

Enable or disable network function level logging.

Syntax

`object.Trace [= { True | False } ]`

Remarks

The **Trace** property is used to enable or disable the logging of network function calls. When enabled, each function call is logged to a file, including the function parameters, return value and error code if applicable. This facility can be enabled and disabled at run time, and the trace log file can be specified by setting the **TraceFile** property. All function calls that are being logged are appended to the trace file, if it exists. If no log file exists when tracing is enabled, the file is created.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

Data Type

Boolean

See Also

[TraceFile Property](#), [TraceFlags Property](#)

TraceFile Property

Gets and sets the name of the file to use when logging network function calls.

Syntax

`object.TraceFile [= filename ]`

Remarks

The **TraceFile** property is used to specify the name of the file that is created when logging is enabled. If this property is set to an empty string (the default value), then a file named **SocketTools.log** is created in the current user's Documents folder. It is recommended that you always specify a complete path to the log file. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

If the file exists, the output is appended to the file, otherwise the file is created. Since logging is enabled per-process, the log file is shared by all instances of the controls being used. If you create multiple instances of the control, you only need to enable logging for a single instance. Because log files can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "0x". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxx:xxxx:xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, the control is attempting to connect to a system with the IPv4 address 192.0.0.1 on port 1234.

If the log file cannot be created, or the user does not have permission to modify an existing file, the error is silently ignored and no output will be generated.

Data Type

String

See Also

TraceFlags Property

Gets and sets the network function logging flags.

Syntax

object.TraceFlags [= *flags*]

Remarks

The **TraceFlags** property is used to specify the type of information written to the trace file when socket function tracing is enabled. The following values may be used:

Value	Description
dnsTraceInfo	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
dnsTraceError	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
dnsTraceWarning	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
dnsTraceHexDump	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
dnsTraceTruncate	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.

Since logging is enabled per-process, the trace flags are shared by all instances of the control being used. If multiple controls have tracing enabled, the **TraceFlags** property should be set to the same value for each control. Changing the trace flags for any one instance of the control will affect the logging performed for all other instances used by the application.

Warnings are generated when a non-fatal error is returned by a Windows Sockets function. For example, if data is being written through the control and an error indicating that the operation would block is returned, only a warning is logged since the application simply needs to attempt to write the data at a later time.

Data Type

Integer (Int32)

See Also

[Trace Property](#), [TraceFile Property](#)

UserName Property

Gets and sets the current user name.

Syntax

object.UserName [= *username*]

Remarks

The **UserName** property specifies the user that is logging in to the server, and is required for authentication purposes.

Data Type

String

See Also

[Password Property](#), [Authenticate Method](#)

Version Property

Return the current version of the control.

Syntax

object.Version

Remarks

The **Version** property returns the current version of the object. This can be used by an application for validation purposes. The version returned is composed of four numbers, separated by periods. The first number is the major version number, the second number is the minor version number, the third is the build number and the fourth is the revision number.

Data Type

String

Network News Transfer Protocol Control Methods

Method	Description
Authenticate	Authenticate the client session
Cancel	Cancels the current blocking network operation
CloseArticle	Closes the current article that has been opened or created
Command	Send a custom command to the server
Connect	Establish a connection with a server
CreateArticle	Creates a new article in the current newsgroup
Disconnect	Terminate the connection with a server
GetArticle	Retrieve a article from the server
GetFirstArticle	Return the first available article in the currently selected newsgroup
GetFirstGroup	Return the first available newsgroup from the server
GetHeaders	Retrieves the headers for the specified article from the server
GetNextArticle	Return the next available article in the currently selected newsgroup
GetNextGroup	Return the next available newsgroup from the server
Initialize	Initialize the control and validate the runtime license key
ListArticles	Return a list of articles in the current newsgroup
ListGroup	Return a list of newsgroups available on the server
OpenArticle	Opens the specified article in the currently selected newsgroup
PostArticle	Post a new article to the current newsgroup
Read	Return data read from the server
Reset	Reset the internal state of the control
SelectGroup	Selects the specified newsgroup as the current newsgroup
StoreArticle	Retrieve an article from the current newsgroup and store it in a local file
Uninitialize	Uninitialize the control and release any system resources that were allocated
Write	Write data to the server

Authenticate Method

Authenticate the client session.

Syntax

object.Authenticate([*UserName*], [*Password*])

Parameters

UserName

An optional string argument which specifies the username used to authenticate the client session. If the argument is omitted, the value assigned to the **UserName** property will be used instead.

Password

An optional string argument which specifies the password used to authenticate the client session. If the argument is omitted, the value assigned to the **Password** property will be used instead.

Return Value

A value of zero is returned if the operation was successful, otherwise a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **Authenticate** method identifies the client to the news server, which may be required to access certain newsgroups or to post articles. If the user name or password is invalid, an error will occur. This method should only be used if the server indicates that authentication is required by returning an error.

See Also

[Password Property](#), [UserName Property](#), [Connect Method](#)

Cancel Method

Cancels the current blocking network operation.

Syntax

object.Cancel

Parameters

None.

Return Value

None.

Remarks

The **Cancel** method cancels any blocking network operation in the current thread. This is typically used inside an event handler, causing the blocking method to return to the caller with an error indicating that the current operation was canceled. This method sets an internal flag that is periodically checked during a blocking operation, such as waiting for more data to arrive. If the current thread is not blocked at the time that this method is called, it will have no effect.

CloseArticle Method

Closes the current article that has been opened or created.

Syntax

object.CloseArticle

Parameters

None.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **CloseArticle** method closes the current article that has been opened or created. If an article is being created, this function actually submits the article to the server. Note that the client application is responsible for generating the message headers as well as the body of the message. News articles conform to the same general characteristics of an email message.

See Also

[CreateArticle Method](#), [OpenArticle Method](#), [Read Method](#), [Write Method](#)

Command Method

Send a custom command to the server.

Syntax

object.Command(Command, [Parameters], [Options])

Parameters

Command

A string which specifies the command to send. Valid commands vary based on the Internet protocol and the type of server that the client is connected to. Consult the protocol standard and/or the technical reference documentation for the server to determine what commands may be issued by a client application.

Parameters

An optional string which specifies one or more parameters to be sent along with the command. If more than one parameter is required, most Internet protocols require that they be separated by a single space character. Consult the protocol standard and/or technical reference documentation for the server to determine what parameters should be provided when issuing a specific command. If no parameters are required for the command, this argument may be omitted.

Options

A numeric value which specifies one or more options. If this argument is omitted, no command options will be used. The following values may be specified:

Value	Description
nntpCommandMultiLine	This option specifies the command will return multiple lines of data. Unlike a single line response, which consists of a result code and result string, a multi-line response consists of one or more lines of text, terminated by a special end-of-data marker.

Return Value

A value of zero is returned if the command was successful. Otherwise, a non-zero error code is returned which indicates the cause of the failure. To determine the result code returned by the server in response to the command, read the value of the **ResultCode** property.

Remarks

The **Command** method sends a command to the server and processes the result code sent back in response to that command. This method can be used to send custom commands to a server to take advantage of features or capabilities that may not be supported internally by the control.

See Also

[ResultCode Property](#), [ResultString Property](#), [OnCommand Event](#)

Connect Method

Establish a connection with a server.

Syntax

object.Connect([RemoteHost], [RemotePort], [UserName], [Password], [Timeout], [Options])

Parameters

RemoteHost

A string which specifies the host name or IP address of the server. If this argument is not specified, it defaults to the value of the **HostAddress** property if it is defined. Otherwise, it defaults to the value of the **HostName** property.

RemotePort

A number which specifies the port to connect to on the server. If this argument is not specified, it defaults to the value of the **RemotePort** property. A value of zero indicates that the default port number for this service should be used to establish the connection.

UserName

A string which specifies the name of the user used to authenticate access to the server. If this argument is not specified, it defaults to the value of the **UserName** property.

Password

A string which specifies the password used to authenticate the user. If this argument is not specified, it defaults to the value of the **Password** property.

Timeout

The number of seconds that the client will wait for a response before failing the operation. If this argument is not specified, the value of the **Timeout** property will be used as the default.

Options

A numeric value which specifies one or more options. If this argument is omitted or a value of zero is specified, a default, standard connection will be established. This argument is constructed by using a bitwise operator with any of the following values:

Value	Description
nntpOptionNone	No additional options are specified when establishing a connection with the server. A standard, non-secure connection will be used.
nntpOptionTunnel	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
nntpOptionTrustedSite	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
nntpOptionSecure	This option specifies the client should attempt to establish a

	secure connection with the server. Note that the server must support secure connections using the TLS protocol.
nntpOptionSecureFallback	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
nntpOptionPreferIPv6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.

Return Value

A value of zero is returned if the connection was successful. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

See Also

CreateArticle Method

Creates a new article in the current newsgroup.

Syntax

object.CreateArticle

Parameters

None.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **CreateArticle** method sends the POST command to the news server. Not all servers permit clients to post articles. The client application is responsible for generating the message headers as well as the body of the message. News articles conform to the same general characteristics of an email message.

The **CloseArticle** method must be called once the contents of the article has been written to the server.

See Also

[GroupName Property](#), [CloseArticle Method](#), [OpenArticle Method](#), [Write Method](#)

Disconnect Method

Terminate the connection with a server.

Syntax

object.Disconnect

Parameters

None.

Return Value

A value of zero is returned if the connection was terminated successfully. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

This method terminates the network connection with the server.

See Also

[IsConnected Property](#), [Connect Method](#), [OnDisconnect Event](#)

GetArticle Method

Retrieve an article from the server.

Syntax

object.GetArticle(*Article*, *Message*, [*Options*])

Parameters

Article

Number of the article to retrieve from the server, or a string that specifies the message ID of the article to retrieve. If an article number is specified, this value must be greater than zero. The first available article in the newsgroup can be determined by checking the value of the **FirstArticle** property. The last available article in the newsgroup is returned by the **LastArticle** property.

Message

A string or byte array which will contain the data transferred from the server when the method returns.

Options

An optional integer value which specifies one or more options. This argument is reserved for future use and should be omitted.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **GetArticle** method is used to retrieve an article from the server and copy it into a local buffer. This method will cause the current thread to block until the article transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

See Also

[FirstArticle Property](#), [LastArticle Property](#), [CreateArticle Method](#), [GetHeaders Method](#), [OpenArticle Method](#), [StoreArticle Method](#), [OnProgress Event](#)

GetFirstArticle Method

Return information about the first article available in the current newsgroup.

Syntax

```
object.GetFirstArticle( Article, [Subject], [Author], [Posted], [MessageId], [References], [ByteCount],  
[LineCount] )
```

Parameters

Article

An integer value which specifies the article ID. This is the number that should be used to access the article on the server. This parameter is required and must be passed by reference.

Subject

An optional string which specifies the subject of the article. This parameter must be passed by reference, or it may be omitted if the program does not require this information.

Author

An optional string which specifies the author of the article. This is typically the name and email address of the user who posted the article. This parameter must be passed by reference, or it may be omitted if the program does not require this information.

Posted

An optional string which specifies the date that the article was posted. This parameter must be passed by reference, or it may be omitted if the program does not require this information.

MessageId

An optional string which specifies the message ID for the article. Although it is more common to reference an article by number, it is possible to reference an article by its message ID. To select a message by its message ID string, set the **MessageID** property. This parameter must be passed by reference, or it may be omitted if the program does not require this information.

References

An optional string which specifies references to the article. This can be used by an application to create a list of cross references to the article so that related threads can be provided to the user. This parameter must be passed by reference, or it may be omitted if the program does not require this information.

ByteCount

An optional integer value which specifies the size of the message in bytes. This parameter must be passed by reference, or it may be omitted if the program does not require this information.

LineCount

An optional integer value which specifies the number of lines of text in the message. This parameter must be passed by reference, or it may be omitted if the program does not require this information.

Return Value

A value of true is returned if the operation was successful, otherwise a return value of false indicates that there are no articles available in the currently selected newsgroup.

Remarks

The **GetFirstArticle** method returns information about the first article in the currently selected newsgroup. This method is used in conjunction with the **GetNextArticle** method to enumerate all of

the articles in the newsgroup. Typically this is used to provide the user with a list of articles to access.

While the articles in the newsgroup are being listed, the client cannot retrieve the contents of a specific article. For example, the **GetArticle** method cannot be called while inside a loop calling **GetNextArticle**. The client should store those articles which it wants to retrieve in an array, and then once all of the articles have been listed, it can begin calling **GetArticle** for each article number to retrieve the article text.

A program should use either the **ListArticles** method or the **GetFirstArticle** and **GetNextArticle** methods, but never in combination with one another.

Example

```
Dim nArticleId As Long
Dim strSubject As String
Dim strAuthor As String
Dim datePosted As Date
Dim strMessageId As String
Dim strReferences As String
Dim nByteCount As Long
Dim nLineCount As Long
Dim bResult As boolean;

' List each article in the current newsgroup, adding the subject to
' a ListBox control
bResult = NntpClient1.GetFirstArticle(nArticleId, strSubject, strAuthor, _
    datePosted, strMessageId, strReferences, _
    nByteCount, nLineCount);

Do While bResult
    List1.AddItem strSubject
    List1.ItemData(List1.NewIndex) = nArticleId

    bResult = NntpClient1.GetNextArticle(nArticleId, strSubject, strAuthor, _
        datePosted, strMessageId, strReferences, _
        nByteCount, nLineCount);
End Do
```

See Also

[Article Property](#), [MessageID Property](#), [GetNextArticle Method](#), [ListArticles Method](#),

GetFirstGroup Method

Return information about the first available newsgroup.

Syntax

object.GetFirstGroup(*GroupName*, [*FirstArticle*], [*LastArticle*], [*Access*])

Parameters

GroupName

An optional string which specifies the name of the newsgroup. This parameter is required and must be passed by reference.

FirstArticle

An optional integer value which specifies the number for the first available article in the newsgroup. This value corresponds to the **FirstArticle** property of a selected newsgroup. This parameter must be passed by reference, or it may be omitted if the program does not require this information.

LastArticle

An optional integer value which specifies the number for the last available article in the newsgroup. This value corresponds to the **LastArticle** property of a selected newsgroup. This parameter must be passed by reference, or it may be omitted if the program does not require this information.

Access

AAAn optional integer value which specifies the access rights for the newsgroup. This parameter must be passed by reference, or it may be omitted if the program does not require this information. It may be one of the following values:

Value	Description
nntpGroupReadOnly	The group is read-only and cannot be modified. Attempts to post articles to the newsgroup will result in an error.
nntpGroupReadWrite	Articles can be posted to the newsgroup. Even though a newsgroup is read-write, it may require that the client authenticate before being given permission to post articles to the server.
nntpGroupModerated	The newsgroup is moderated and articles can only be posted by the group moderator. To request that an article be posted to the newsgroup, you must email the message to the moderator.

Return Value

A value of true is returned if the operation was successful, otherwise a return value of false indicates that there are no newsgroups available on the server. Note that if no newsgroups are returned by the server, it may indicate that it requires the client to authenticate itself prior to requesting a list of groups or articles.

Remarks

The **GetFirstGroup** method returns information about the first newsgroup on the server. This method is used in conjunction with the **GetNextGroup** method to enumerate all of the available newsgroups. Typically this is used to provide the user with a list of newsgroups to select. If the **LastUpdate** property is set, then only newsgroups that have been created since that date will be returned.

While the newsgroups are being listed, the client cannot select a newsgroup or retrieve the contents

of a specific article. The client should store those newsgroups which it wants to retrieve articles from, and then once all of the newsgroups have been listed, it can then select each newsgroup and retrieve the available articles from that group.

A program should use either the **ListGroups** method or the **GetFirstGroup** and **GetNextGroup** methods, but never in combination with one another.

Example

```
Dim strGroupName As String
Dim bResult As boolean;

' List each newsgroup available on the server, adding the group name
' to a ListBox control
bResult = NntpClient1.GetFirstGroup(strGroupName)

Do While bResult
    List1.AddItem strGroupName
    bResult = NntpClient1.GetNextGroup(strGroupName)
End Do
```

See Also

[GroupName Property](#), [GroupTitle Property](#), [LastUpdate Property](#), [GetNextGroup Method](#), [ListGroups Method](#)

GetHeaders Method

Retrieves the headers for the specified article from the server.

Syntax

object.GetHeaders(*Article*, *Headers*)

Parameters

Article

Number of article to retrieve from the server, or a string that specifies the message ID of the article header to retrieve. If an article number is specified, this value must be greater than zero. The first available article in the newsgroup can be determined by checking the value of the **FirstArticle** property. The last available article in the newsgroup is returned by the **LastArticle** property.

Headers

A string or byte array which will contain the data transferred from the server when the method returns. This parameter must be passed by reference.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **GetHeaders** method is used to retrieve an article header block from the server and copy it into a local buffer. This method will cause the current thread to block until the article transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

See Also

[CreateArticle Method](#), [GetArticle Method](#), [OpenArticle Method](#), [OnProgress Event](#)

GetNextArticle Method

Return information about the next article available in the current newsgroup.

Syntax

```
object.GetNextArticle( Article, [Subject], [Author], [Posted], [MessageId], [References], [ByteCount],  
[LineCount] )
```

Parameters

Article

An integer value which specifies the article ID. This is the number that should be used to access the article on the server. This parameter is required and must be passed by reference.

Subject

An optional string which specifies the subject of the article. This parameter must be passed by reference, or it may be omitted if the program does not require this information.

Author

An optional string which specifies the author of the article. This is typically the name and email address of the user who posted the article. This parameter must be passed by reference, or it may be omitted if the program does not require this information.

Posted

An optional string which specifies the date that the article was posted. This parameter must be passed by reference, or it may be omitted if the program does not require this information.

MessageId

An optional string which specifies the message ID for the article. Although it is more common to reference an article by number, it is possible to reference an article by its message ID. To select a message by its message ID string, set the **MessageID** property. This parameter must be passed by reference, or it may be omitted if the program does not require this information.

References

An optional string which specifies references to the article. This can be used by an application to create a list of cross references to the article so that related threads can be provided to the user. This parameter must be passed by reference, or it may be omitted if the program does not require this information.

ByteCount

An optional integer value which specifies the size of the message in bytes. This parameter must be passed by reference, or it may be omitted if the program does not require this information.

LineCount

An optional integer value which specifies the number of lines of text in the message. This parameter must be passed by reference, or it may be omitted if the program does not require this information.

Return Value

A value of true is returned if the operation was successful, otherwise a return value of false indicates that there are no more articles available in the currently selected newsgroup.

Remarks

The **GetNextArticle** method returns information about the next available article in the currently selected newsgroup. This method is used in conjunction with the **GetFirstArticle** method to

enumerate all of the articles in the newsgroup. Typically this is used to provide the user with a list of articles to access.

While the articles in the newsgroup are being listed, the client cannot retrieve the contents of a specific article. For example, the **GetArticle** method cannot be called while inside a loop calling **GetNextArticle**. The client should store those articles which it wants to retrieve in an array, and then once all of the articles have been listed, it can begin calling **GetArticle** for each article number to retrieve the article text.

A program should use either the **ListArticles** method or the **GetFirstArticle** and **GetNextArticle** methods, but never in combination with one another.

Example

```
Dim nArticleId As Long
Dim strSubject As String
Dim strAuthor As String
Dim datePosted As Date
Dim strMessageId As String
Dim strReferences As String
Dim nByteCount As Long
Dim nLineCount As Long
Dim bResult As boolean;

' List each article in the current newsgroup, adding the subject to
' a ListBox control
bResult = NntpClient1.GetFirstArticle(nArticleId, strSubject, strAuthor, _
    datePosted, strMessageId, strReferences, _
    nByteCount, nLineCount);

Do While bResult
    List1.AddItem strSubject
    List1.ItemData(List1.NewIndex) = nArticleId

    bResult = NntpClient1.GetNextArticle(nArticleId, strSubject, strAuthor, _
        datePosted, strMessageId, strReferences, _
        nByteCount, nLineCount);
End Do
```

GetNextGroup Method

Return information about the next available newsgroup.

Syntax

object.GetNextGroup(*GroupName*, [*FirstArticle*], [*LastArticle*], [*Access*])

Parameters

GroupName

An optional string which specifies the name of the newsgroup. This parameter is required and must be passed by reference.

FirstArticle

An optional integer value which specifies the number for the first available article in the newsgroup. This value corresponds to the **FirstArticle** property of a selected newsgroup. This parameter must be passed by reference, or it may be omitted if the program does not require this information.

LastArticle

An optional integer value which specifies the number for the last available article in the newsgroup. This value corresponds to the **LastArticle** property of a selected newsgroup. This parameter must be passed by reference, or it may be omitted if the program does not require this information.

Access

An optional integer value which specifies the access rights for the newsgroup. This parameter must be passed by reference, or it may be omitted if the program does not require this information. It may be one of the following values:

Value	Description
nntpGroupReadOnly	The group is read-only and cannot be modified. Attempts to post articles to the newsgroup will result in an error.
nntpGroupReadWrite	Articles can be posted to the newsgroup. Even though a newsgroup is read-write, it may require that the client authenticate before being given permission to post articles to the server.
nntpGroupModerated	The newsgroup is moderated and articles can only be posted by the group moderator. To request that an article be posted to the newsgroup, you must email the message to the moderator.

Return Value

A value of true is returned if the operation was successful, otherwise a return value of false indicates that there are no more newsgroups available on the server. Note that if no newsgroups are returned by the server, it may indicate that it requires the client to authenticate itself prior to requesting a list of groups or articles.

Remarks

The **GetNextGroup** method returns information about the next available newsgroup on the server. This method is used in conjunction with the **GetFirstGroup** method to enumerate all of the available newsgroups. Typically this is used to provide the user with a list of newsgroups to select. If the **LastUpdate** property is set, then only newsgroups that have been created since that date will be returned.

While the newsgroups are being listed, the client cannot select a newsgroup or retrieve the contents of a specific article. The client should store those newsgroups which it wants to retrieve articles from, and then once all of the newsgroups have been listed, it can then select each newsgroup and retrieve the available articles from that group.

A program should use either the **ListGroups** method or the **GetFirstGroup** and **GetNextGroup** methods, but never in combination with one another.

Example

```
Dim strGroupName As String
Dim bResult As boolean;

' List each newsgroup available on the server, adding the group name
' to a ListBox control
bResult = NntpClient1.GetFirstGroup(strGroupName)

Do While bResult
    List1.AddItem strGroupName
    bResult = NntpClient1.GetNextGroup(strGroupName)
End Do
```

See Also

[GroupName Property](#), [GroupTitle Property](#), [LastUpdate Property](#), [GetFirstGroup Method](#), [ListGroups Method](#)

Initialize Method

Initialize the control and validate the runtime license key.

Syntax

```
object.Initialize( [LicenseKey] )
```

Parameters

LicenseKey

An optional string value which specifies a runtime license key used to initialize the control. If the license key is omitted or passed as an empty string, a development license must be installed on the local system.

Return Value

A value of zero is returned if the control was initialized successfully. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

This method dynamically loads other system libraries and allocates thread local storage. In most cases, it is not necessary to call this method directly because it is automatically invoked when an instance of the control is created by the container. However, if the control is created dynamically using **CreateObject** or a similar method, this must be the first method that is called before you attempt to modify any property values or invoke other methods. Failure to initialize the control may result in subsequent errors and/or cause an exception to be raised.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the control will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the control was created.

If the control is being used within another DLL, it is important that you do not attempt to create an instance of the control or call the **Initialize** method from within the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is written in C++ and it is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for any static and global C++ objects and has the same restrictions.

Example

```
Set nntpClient = CreateObject("SocketTools.NntpClient.12")

nError = nntpClient.Initialize(strLicenseKey)
If nError > 0 Then
    MsgBox "Unable to initialize SocketTools component"
End
End If
```

See Also

[IsInitialized Property](#), [Uninitialize Method](#)

ListArticles Method

Return a list of articles in the current newsgroup.

Syntax

object.ListArticles([*FirstArticle*], [*LastArticle*])

Parameters

FirstArticle

An optional integer argument which specifies the first article to list. If this argument is omitted, the list will start with the first available article in the newsgroup.

LastArticle

An optional integer argument which specifies the last article to list. If this argument is omitted, the list will end with the last available article in the newsgroup.

Return Value

A value of zero is returned if the operation was successful, otherwise a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **ListArticles** method requests that the server return a list of news articles in the specified range for the current newsgroup. The **OnNewsArticle** event will be fired for each article returned by the server. When the last news article has been listed, the **OnLastArticle** event will be fired.

While the articles in the newsgroup are being listed, the client cannot retrieve the contents of a specific article. For example, the **GetArticle** method cannot be called while inside the **OnNewsArticle** event. The client should store those articles which it wants to retrieve in an array, and then once all of the articles have been listed, it can begin calling **GetArticle** for each article number to retrieve the article text.

A program should use either the **ListArticles** method or the **GetFirstArticle** and **GetNextArticle** methods, but never in combination with one another.

See Also

[FirstArticle Property](#), [LastArticle Property](#), [GetFirstArticle Method](#), [GetNextArticle Method](#), [SelectGroup Method](#), [OnLastArticle Event](#), [OnNewsArticle Event](#)

ListGroups Method

Return a list of newsgroups available on the server.

Syntax

object.ListGroups([*LastUpdate*])

Parameters

LastUpdate

An optional string argument which specifies the date and time that the list of newsgroups were last retrieved from the server. If this argument is omitted, then the value of the **LastUpdate** property will be used. If the value is an empty string, all available newsgroups will be listed by the server.

Return Value

A value of zero is returned if the operation was successful, otherwise a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **ListGroups** method requests that the server return a list of available news groups. The **OnNewsGroup** event will be fired for each group returned by the server. When the last news group has been listed by the control, the **OnLastGroup** event will fire.

While the newsgroups are being listed, the client cannot select a newsgroup or retrieve the contents of a specific article. The client should store those newsgroups which it wants to retrieve articles from, and then once all of the newsgroups have been listed, it can then select each newsgroup and retrieve the available articles from that group.

A program should use either the **ListGroups** method or the **GetFirstGroup** and **GetNextGroup** methods, but never in combination with one another.

See Also

[GroupName Property](#), [LastUpdate Property](#), [GetFirstGroup Property](#), [GetNextGroup Property](#), [OnLastGroup Event](#), [OnNewsGroup Event](#)

OpenArticle Method

Opens the specified article in the currently selected newsgroup.

Syntax

object.OpenArticle(*Article*, [*Options*])

Parameters

Article

Number of the article to retrieve from the server. This value must be greater than zero. The first available article in the newsgroup can be determined by checking the value of the **FirstArticle** property. The last available article in the newsgroup is returned by the **LastArticle** property.

Options

An optional integer value which specifies one or more options. This argument is reserved for future use and should be omitted.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **OpenArticle** method opens the specified article in the currently selected newsgroup. The article data can be read using the **Read** method, and once all of the data has been returned, the **CloseArticle** method should be used to close the article on the server.

See Also

[FirstArticle Property](#), [LastArticle Property](#), [CloseArticle Method](#), [CreateArticle Method](#), [Read Method](#)

PostArticle Method

Post a new article to the current newsgroup.

Syntax

object.PostArticle(*Message*, [*Options*])

Parameters

Message

A string or byte array which will contain the article to be posted to the server.

Options

An optional integer value which specifies one or more options. This argument is reserved for future use and should be omitted.

Return Value

A value of zero is returned if the operation was successful, otherwise a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **PostArticle** method is used to submit the contents of the specified buffer to the server as a new article in the current newsgroup. This method will cause the current thread to block until the article transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

Not all newsgroups permit new articles to be posted, and some newsgroups may require that you email the article to a moderator for approval instead of posting directly to the group. It may be required that the client authenticate itself using the **Authenticate** method prior to posting the article.

A news article is similar to an email message in that it contains one or more header fields, followed by an empty line, followed by the body of the article. Each line of text should be terminated by a carriage return/linefeed sequence of characters. The Mail Message control can be used to compose a message if needed. Note that the article header must contain a header field named "Newsgroups" with a value that specifies the newsgroup or newsgroups the article is being posted to. If this header field is missing, the news server will reject the article.

See Also

[Authenticate Method](#), [GetArticle Method](#), [GetHeaders Method](#), [OnProgress Event](#)

Read Method

Return data read from the server.

Syntax

object.Read(*Buffer*, [*Length*])

Parameters

Buffer

A buffer that the data will be stored in. If the variable is a **String** then the data will be returned as a string of characters. If the data returned by the server contains UTF-8 encoded text, it will automatically be converted to standard UTF-16 Unicode text. If you wish to read the data without conversion, provide a **Byte** array as the buffer. This parameter must be passed by reference.

Length

A numeric value which specifies the number of bytes to read. Its maximum value is $2^{31}-1 = 2147483647$. This argument is required to be present for string data. If a value is specified for this argument for other permissible types of data, and it is less than number of bytes that is determined by the control, then **Length** will override the internally computed value. If the argument is omitted, then the maximum number of bytes to read is determined by the size of the buffer.

Return Value

The number of bytes actually read from the server is returned by this method. If an error occurs, NNTP_ERROR is returned.

Remarks

The **Read** method returns data that has been read from the server, up to the number of bytes specified. If no data is available to be read, an error will be generated if the control is non-blocking mode. If the control is in blocking mode, the program will wait until data is returned by the server or the connection is closed.

See Also

[IsConnected Property](#), [IsReadable Property](#), [Write Method](#), [OnRead Event](#), [OnWrite Event](#)

Reset Method

Reset the internal state of the control.

Syntax

object.Reset

Parameters

None.

Return Value

None.

Remarks

The **Reset** method resets the internal state of the control. Property values are initialized to their internal defaults, open network connections will be closed and any handles allocated by the control will be released.

See Also

[Cancel Method](#), [Initialize Method](#), [Uninitialize Method](#)

SelectGroup Method

Selects the specified newsgroup as the current newsgroup.

Syntax

object.SelectGroup(*GroupName*)

Parameters

GroupName

A string which specifies the name of the newsgroup to select.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **SelectGroup** method selects a newsgroup and updates the control with information about the group. The list of available newsgroups can be enumerated using the **ListGroups** method.

See Also

[FirstArticle Property](#), [GroupName Property](#), [LastArticle Property](#), [ListGroups Method](#)

StoreArticle Method

Retrieve an article from the current newsgroup and store it in a local file.

Syntax

object.StoreArticle(Article, FileName)

Parameters

Article

Number of the article to retrieve from the server. This value must be greater than zero. The first available article in the newsgroup can be determined by checking the value of the **FirstArticle** property. The last available article in the newsgroup is returned by the **LastArticle** property.

FileName

Pointer to a string which specifies the file that the article will be stored in. If an empty string is passed as an argument, the article is copied to the system clipboard.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **StoreArticle** method retrieves an article from the server and stores it in a file on the local system. The contents of the article is stored as a text file, using the specified file name. This method will cause the current thread to block until the message transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

See Also

[GetArticle Method](#), [OpenArticle Method](#)

Uninitialize Method

Uninitialize the control and release any system resources that were allocated.

Syntax

object.Uninitialize

Parameters

None.

Return Value

None.

Remarks

The **Uninitialize** method terminates any connection established by the control and resets the internal state of the control. This method is not typically used because any resources that have been allocated by an instance of the control will automatically be released when it is destroyed.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the control will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the control was created. An application should only call the **Uninitialize** method if it has explicitly called the **Initialize** method.

See Also

[Initialize Method](#)

Write Method

Write data to the server.

Syntax

object.Write(*Buffer*, [*Length*])

Parameters

Buffer

A buffer variable that contains the data to be written to the server. If the variable is a **String** type, then the data will be written as a string of characters. This is the most appropriate data type to use because the server expects text data that consists of printable characters. If the string contains Unicode characters, it will be automatically converted to use standard UTF-8 encoding prior to being sent. If you wish to send the data without conversion, use a **Byte** array as the buffer instead of a **String** variable.

Length

A numeric value which specifies the number of bytes to write. Its maximum value is $2^{31}-1 = 2147483647$. If a value is specified for this argument and it is greater than the actual size of the buffer, then the **Length** argument will be ignored and the entire contents of the buffer will be written. If the argument is omitted, then the maximum number of bytes to write is determined by the size of the buffer.

Return Value

This method returns the number of bytes actually written to the server, or NNTP_ERROR if an error was encountered.

Remarks

The **Write** method sends the data in *buffer* to the server. If the connection is buffered, as is typically the case, the data is copied to the send buffer and control immediately returns to the program. If the control is blocking, the application will wait until the data can be sent. If the control is non-blocking and the write fails because it could not send all of the data to the server, the **OnWrite** event will be fired when the server can accept data again.

See Also

[IsConnected Property](#), [IsWritable Property](#), [Timeout Property](#), [Read Method](#), [OnWrite Event](#)

Network News Transfer Protocol Control Events

Event	Description
OnCancel	This event occurs when a blocking operation is canceled
OnCommand	This event occurs when the server processes a command issued by the client
OnConnect	This event occurs when a connection is established
OnDisconnect	This event occurs when a connection is terminated
OnError	This event occurs when a control error occurs
OnLastArticle	This event occurs after the last news article has been returned by the server
OnLastGroup	This event occurs after the last newsgroup has been returned by the server
OnNewsArticle	This event occurs when the server returns information about an article
OnNewsGroup	This event occurs when the server returns information about a newsgroup
OnProgress	This event occurs during data transfer
OnRead	This event occurs when data is available to be read
OnWrite	This event occurs when data can be written to the server

OnCancel Event

The **OnCancel** event is generated when a blocking operation is canceled.

Syntax

Sub *object_OnCancel* ([*Index As Integer*])

Remarks

This event occurs when a blocking operation on the socket, such as sending or receiving data, is canceled with the **Cancel** method. To assist in determining which operation was canceled, consult the **State** property.

See Also

[Cancel Method](#), [OnError Event](#), [OnTimeout Event](#)

OnCommand Event

The **OnCommand** event is generated when the client sends a command to the server and receives a reply indicating the results of that command.

Syntax

```
Sub object_OnCommand( [Index As Integer], ByVal ResultCode As Variant, ByVal ResultString As Variant )
```

Remarks

The **OnCommand** event is generated when the client receives a reply from the server after some action has been taken. The **ResultCode** argument contains the numeric result code returned by the server. The result codes returned from the server fall into one of the following categories:

Value	Description
100-199	Positive preliminary result. This indicates that the requested action is being initiated, and the client should expect another reply from the server before proceeding.
200-299	Positive completion result. This indicates that the server has successfully completed the requested action.
300-399	Positive intermediate result. This indicates that the requested action cannot complete until additional information is provided to the server.
400-499	Transient negative completion result. This indicates that the requested action did not take place, but the error condition is temporary and may be attempted again.
500-599	Permanent negative completion result. This indicates that the requested action did not take place.

The **ResultString** argument contains the descriptive string returned by the server which describes the result. The string contents may vary depending on the type of server.

See Also

[ResultCode Property](#), [ResultString Property](#), [Command Method](#)

OnConnect Event

The **OnConnect** event is generated when a connection is established.

Syntax

Sub *object_OnConnect* ([*Index As Integer*])

Remarks

The **OnConnect** event is generated when a connection is made with a server as a result of a **Connect** method call. This event is only triggered when the **Blocking** property is set to False.

See Also

[Blocking Property](#), [Connect Method](#), [OnDisconnect Event](#), [OnWrite Event](#)

OnDisconnect Event

The **OnDisconnect** event is generated when a connection is terminated.

Syntax

Sub *object_OnDisconnect* ([*Index As Integer*])

Remarks

The **OnDisconnect** event is generated when the connection is terminated by the server. This event is only triggered when the **Blocking** property is set to False.

When the **OnDisconnect** event fires, it is possible that there may still be buffered data available to read from the server. Before disconnecting from the server, the application should attempt to read any remaining data until the **Read** method returns a value of zero, or returns an error indicating that the operation would block.

See Also

[Blocking Property](#), [IsConnected Property](#), [IsReadable Property](#), [Connect Method](#), [Disconnect Method](#), [Read Method](#), [OnConnect Event](#)

OnError Event

The **OnError** event is generated when a control error occurs.

Syntax

```
Sub object_OnError ( [Index As Integer,] ByVal ErrorCode As Variant, ByVal Description As Variant )
```

Remarks

This event occurs when an error occurs during a control action. Errors not generated by the control itself, such as errors related to the programming language or general component errors, do not trigger this event.

The ***ErrorCode*** argument specifies the last error that has occurred. If the error is network related, the error code values returned by the component correspond to those returned by the standard Windows Sockets library.

The ***Description*** argument is a string that describes the error.

See Also

[LastError Property](#), [LastErrorString Property](#), [ThrowError Property](#)

OnLastArticle Event

The **OnLastArticle** event is generated after the last news article has been returned by the server.

Syntax

Sub *object_OnLastArticle*([*Index As Integer*])

Remarks

The **OnLastArticle** event is fired after the server has returned all of the articles in the current newsgroup as a result of the application calling the **ListArticles** method.

See Also

[ListArticles Method](#), [OnNewsArticle Event](#)

OnLastGroup Event

The **OnLastGroup** event is generated after the last newsgroup has been returned by the server.

Syntax

Sub *object_OnLastGroup*([*Index As Integer*])

Remarks

The **OnLastGroup** event is fired after the server has returned all of the available newsgroups as a result of the application calling the **ListGroups** method.

See Also

[ListGroups Method](#), [OnNewsGroup Event](#)

OnNewsArticle Event

The **OnNewsArticle** event is generated when the server returns information about an article.

Syntax

Sub *object_OnNewsArticle*([*Index As Integer*,] **ByVal** *Article As Variant*, **ByVal** *Subject As Variant*, **ByVal** *Author As Variant*, **ByVal** *Posted As Variant*, **ByVal** *MessageId As Variant*, **ByVal** *References As Variant*, **ByVal** *ByteCount As Variant*, **ByVal** *LineCount As Variant*)

Remarks

The **OnNewsArticle** event is generated when the server returns information about an article in the current newsgroup. Calling the **ListArticles** method causes this event to be generated for each article in the newsgroup. The following arguments are passed to the event handler:

Article

An integer value which specifies the article ID. This is the number that should be used to access the article on the server.

Subject

A string value which specifies the subject of the article.

Author

A string value which specifies the author of the article. This is typically the name and email address of the user who posted the article.

Posted

A string value which specifies the date that the article was posted.

MessageId

A string value which specifies the message ID for the article. Although it is more common to reference an article by number, it is possible to reference an article by its message ID. To select a message by its message ID string, set the **MessageID** property.

References

A string which specifies references to the article. This can be used by an application to create a list of cross references to the article so that related threads can be provided to the user.

ByteCount

An integer value which specifies the size of the message in bytes.

LineCount

An integer value which specifies the number of lines of text in the message.

See Also

[Article Property](#), [MessageID Property](#), [ListArticles Method](#), [OnLastArticle Event](#)

OnNewsGroup Event

The **OnNewsGroup** event is generated when the server returns information about a newsgroup.

Syntax

```
Sub object_OnNewsGroup( [Index As Integer,] ByVal GroupName As Variant, ByVal FirstArticle As Variant, ByVal LastArticle As Variant, ByVal Access As Variant )
```

Remarks

The **OnNewsGroup** event is generated when the server returns information about a newsgroup. Calling the **ListGroups** method causes this event to be generated for each newsgroup on the server. The following arguments are passed to the event handler:

GroupName

A string value which specifies the name of the newsgroup.

FirstArticle

An integer value which specifies the number for the first available article in the newsgroup. This value corresponds to the **FirstArticle** property of a selected newsgroup.

LastArticle

An integer value which specifies the number for the last available article in the newsgroup. This value corresponds to the **LastArticle** property of a selected newsgroup.

Access

An integer value which specifies the access rights for the newsgroup. It may be one of the following values:

Value	Description
nntpGroupReadOnly	The group is read-only and cannot be modified. Attempts to post articles to the newsgroup will result in an error.
nntpGroupReadWrite	Articles can be posted to the newsgroup. Even though a newsgroup is read-write, it may require that the client authenticate before being given permission to post articles to the server.
nntpGroupModerated	The newsgroup is moderated and articles can only be posted by the group moderator. To request that an article be posted to the newsgroup, you must email the message to the moderator.

See Also

[GroupName Property](#), [GroupTitle Property](#), [ListGroups Method](#), [OnLastGroup Event](#)

OnProgress Event

The **OnProgress** event is generated during data transfer.

Syntax

Sub *object_OnProgress* ([*Index As Integer*], **ByVal** *Article As Variant*, **ByVal** *ArticleSize As Variant*, **ByVal** *ArticleCopied As Variant*, **ByVal** *Percent As Variant*)

Remarks

The **OnProgress** event is generated during the transfer of data between the client and server, indicating the amount of data exchanged. For transfers of large amounts of data, this event can be used to update a progress bar or other user-interface control to provide the user with some visual feedback. The arguments to this event are:

Article

An integer value which specifies the number of the article being retrieved. If an article is being posted, this argument will have a value of zero.

ArticleSize

The size of the article being transferred in bytes.

ArticleCopied

The number of bytes that have been transferred between the client and server.

Percent

The percentage of data that's been transferred, expressed as an integer value between 0 and 100, inclusive. If the size of the file on the server cannot be determined, this value will always be 100.

Note that this event is only generated when a news article is transferred using the **GetArticle** or **PostArticle** methods. If the client is reading or writing the file data directly to the server using the **Read** or **Write** methods then the application is responsible for calculating the completion percentage and updating any user interface controls.

See Also

[GetArticle Method](#), [PostArticle Method](#)

OnRead Event

The **OnRead** event is generated when data is available to be read.

Syntax

Sub *object_OnRead* ([*Index As Integer*])

Remarks

The **OnRead** event is generated for non-blocking sockets when data is available to be read from the server. Use the **Read** method to read the data. This event is only triggered when the **Blocking** property is set to False.

See Also

[IsReadable Property](#), [Read Method](#), [Write Method](#), [OnWrite Event](#)

OnTimeout Event

The **OnTimeout** event is fired when a blocking operation times out.

Syntax

Sub *object_OnTimeout* ([*Index As Integer*])

Remarks

The **OnTimeout** event is generated when a blocking socket operation, such as sending or receiving data, times out. To determine which operation was in progress when the timeout occurred, consult the **State** property. This event is only triggered when the **Blocking** property is set to True.

See Also

[Timeout Property](#), [OnCancel Event](#)

OnWrite Event

The **OnWrite** event is generated when data can be written to the server.

Syntax

Sub *object_OnWrite* ([*Index As Integer*])

Remarks

The **OnWrite** event is generated for non-blocking sockets when data can be written to the server after a previous attempt failed because it would cause the control to block. This event is only triggered when the **Blocking** property is set to False.

[IsWritable Property](#), [Read Method](#), [Write Method](#), [OnConnect Event](#), [OnRead Event](#)

Post Office Protocol Control

List and retrieve email messages from a mail server.

Reference

- [Properties](#)
- [Methods](#)
- [Events](#)
- [Error Codes](#)

Control Information

Object Name	PopClientCtl.PopClient
File Name	CSPOPX12.OCX
Version	12.0.3024.1286
ProgID	SocketTools.PopClient.12
ClassID	E11C6491-C900-47F3-A243-CE5119A4DE5E
Threading Model	Apartment
Help File	CST12CTL.CHM
Dependencies	None
Standards	RFC 1939

Overview

The Post Office Protocol (POP3) provides access to a user's new email messages on a mail server. Methods are provided for listing available messages and then retrieving those messages, storing them either in files or in memory. Once a user's messages have been downloaded to the local system, they are typically removed from the server. This is the most popular email protocol used by Internet Service Providers (ISPs) and the control provides a complete interface for managing a user's mailbox. This control is typically used in conjunction with the Mail Message control, which is used to process the messages that are retrieved from the server.

The control supports secure explicit and implicit connections using TLS 1.2 or later with client certificates for authentication. By simply setting a few properties, a secure connection using 256-bit AES encryption can be established, providing your application with the highest level of security available. Authentication is supported using both standard passwords and OAuth bearer tokens.

Requirements

The SocketTools ActiveX Edition components are self-registering controls that are compatible with any programming language that supports the Component Object Model (COM) and the ActiveX control specification. If you are using Visual Basic 6.0, Service Pack 6 (SP6) is required. We recommend installing all available updates for your development tools. Although the Visual Basic 6.0 runtime is supported on Windows 11, the IDE itself is no longer officially supported by Microsoft. Legacy IDEs and compilers may also require elevated (administrator) privileges to run properly.

The ActiveX controls are supported on Windows 7, Windows Server 2008 R2, and later versions of both desktop and server editions of Windows. For Windows 7, Service Pack 1 (SP1) is the minimum

requirement. For Windows 8 systems, the 8.1 update must be installed. On ARM-based platforms, the minimum supported version is Windows 10 build 1709.

SocketTools includes components for both 32-bit (x86) and 64-bit (x64) Windows platforms. All modern versions of Windows are 64-bit, but we continue to include 32-bit components for compatibility with legacy development tools such as Visual Basic 6.0. We also provide native ARM64 ActiveX controls for systems running Windows on ARM. Note that 32-bit applications on ARM run using x86 emulation, and Microsoft no longer supports native ARM32 applications.

If you are using VBScript, Visual Basic for Applications (VBA), or another scripting environment on an ARM-based system, be aware that 64-bit hosts will require ARM64 components, while 32-bit hosts will use x86 components under emulation. This includes applications created with Visual Basic 6.0. To reduce deployment complexity and avoid confusion, SocketTools does not include ARM32 ActiveX controls in its standard redistribution packages but they are available on request for legacy or specialized scenarios.

Distribution

When you distribute an application that uses this control, you can either install the file in the same folder as your application executable or as a shared component in the appropriate system folder. If you install the control in the system folder, it is important that you distribute the correct version for the target platform and it must be registered. If you install the control in the same folder as your executable, it is recommended that you use registration-free activation or COM redirection to ensure that the correct version of the control is loaded by the application.

Post Office Protocol Control Properties

Property	Description
AuthType	Gets and sets the method used to authenticate the user
AutoResolve	Determines if host names and IP addresses are automatically resolved
BearerToken	Gets and sets the OAuth 2.0 bearer token used for authentication
Blocking	Gets and sets the blocking state of the control
CertificateExpires	Return the date and time that the server certificate expires
CertificateIssued	Return the date and time that the server certificate was issued
CertificateIssuer	Returns information about the organization that issued the server certificate
CertificateName	Gets and sets the common name for the client certificate
CertificatePassword	Gets and sets the password associated with the client certificate
CertificateStatus	Return the status of the server certificate
CertificateStore	Gets and sets the name of the client certificate store or file
CertificateSubject	Returns information about the organization to which the server certificate was issued
CertificateUser	Gets and sets the user that owns the client certificate
CipherStrength	Return the length of the key used by the encryption algorithm
HashStrength	Return the length of the message digest that was selected
HeaderField	Gets and sets the current header field name
HeaderValue	Return the value of the current header field
HostAddress	Gets and sets the IP address of the mail server
HostName	Gets and sets the host name of the mail server
IsBlocked	Return if the control is blocked performing an operation
IsConnected	Determine if the control is connected to a server
IsInitialized	Determine if the control has been initialized
IsReadable	Return if data can be read from the server without blocking
IsWritable	Return if data can be sent to the server without blocking
LastError	Gets and sets the last error that occurred on the control
LastErrorString	Return a description of the last error to occur
LastMessage	Return the number of the last message available on the server
MailboxSize	Return the size of the current mailbox
Message	Gets and sets the current message number
MessageCount	Return the number of messages available in the current mailbox
MessageFrom	Return the address of the user who sent the message
MessageUID	Return the unique ID for the current message on the mail server
MessageSize	Return the size of the current message in bytes

Options	Gets and sets the options that are used in establishing a connection
Password	Gets and sets the password for the current user
RemotePort	Gets and sets the port number for a remote connection
ResultCode	Return the result code of the previous action
ResultString	Return a string describing the results of the previous action
Secure	Set or return if a connection to the server is secure
SecureCipher	Return the encryption algorithm used to establish the secure connection with the server
SecureHash	Return the message digest selected when establishing the secure connection with the server
SecureKeyExchange	Return the key exchange algorithm used to establish the secure connection with the server
SecureProtocol	Gets and sets the security protocol used to establish the secure connection with the server
ThrowError	Enables or disables error handling by the application
Timeout	Gets and sets the amount of time until a blocking operation fails
Trace	Enable or disable socket function level tracing
TraceFile	Specify the socket function trace output file
TraceFlags	Gets and sets the socket function tracing flags
UserName	Gets and sets the current user name
Version	Return the current version of the control

AuthType Property

Gets and sets the method used to authenticate the user.

Syntax

object.AuthType [= *type*]

Remarks

The **AuthType** property specifies the type of authentication that should be used when the client connects to the mail server. The following authentication methods are supported:

Value	Description
popAuthPass	The username and password is sent to the server using the USER and PASS commands. This authentication method is supported by most servers and is the default authentication type. The credentials are not encrypted and this method should only be used over secure connections.
popAuthApop	The APOP authentication method which uses an MD5 digest of the password. This method has been deprecated is not supported by all servers. It should only be used if required by legacy mail servers which do not support the SASL authentication methods.
popAuthLogin	This authentication type will use the AUTH LOGIN command to authenticate the client session. This encodes the username and password in a specific format, but the credentials are not encrypted. It should be used over a secure connection. The server must support the Simple Authentication and Security Layer (SASL) mechanism as defined in RFC 4422.
popAuthPlain	This authentication type will use the AUTH PLAIN command to authenticate the client session. This encodes the username and password in a specific format, but the credentials are not encrypted. It should be used over a secure connection. The server must support the PLAIN Simple Authentication and Security Layer (SASL) mechanism as defined in RFC 4616.
popAuthXOAuth2	This authentication type will use the AUTH XOAUTH2 command to authenticate the client session. This authentication method does not require the user password, instead the BearerToken property must specify the bearer token issued by the service provider.
popAuthBearer	This authentication type will use the AUTH OAUTHBEARER command to authenticate the client session as defined in RFC 7628. This authentication method does not require the user password, instead the BearerToken property must specify the bearer token issued by the service provider.

Data Type

Integer (Int32)

Remarks

The **popAuthLogin** and **popAuthPlain** authentication methods require the mail server support the Simple Authentication and Security Layer (SASL) AUTH command as defined in RFC 5034. Most modern mail servers do support one or both of these methods, and they are generally preferred over the **popAuthPass** method when possible. However, for backwards compatibility with legacy servers, the API will default to using **popAuthPass** for client authentication.

The **popAuthXOAuth2** and **popAuthBearer** authentication methods are similar, but they are not interchangeable. Both use an OAuth 2.0 bearer token to authenticate the client session, but they differ in how the token is presented to the server. It is currently preferable to use the XOAUTH2 method because it is more widely available and some service providers do not yet support the OAUTHBEARER method.

Changing the value of the **BearerToken** property will automatically set the current authentication method to use OAuth 2.0.

See Also

[BearerToken Property](#), [Password Property](#), [UserName Property](#), [Connect Method](#)

AutoResolve Property

Determines if host names and IP addresses are automatically resolved.

Syntax

object.AutoResolve [= { True | False }]

Remarks

Setting the **AutoResolve** property determines if the control automatically resolves host names and addresses specified by the **HostName** and **HostAddress** properties. If set to True, setting the **HostName** property will cause the control to automatically determine the corresponding IP address and set the **HostAddress** property accordingly. Likewise, setting the **HostAddress** property will cause the control to determine the host name and set the **HostName** property. Setting the property to False prevents the control from resolving host names until a connection attempt is made.

Note that setting the **HostName** or **HostAddress** property may cause the current thread to block, sometimes for several seconds, until the name or address is resolved. To prevent this behavior, set **AutoResolve** to False.

Data Type

Boolean

See Also

[HostAddress Property](#), [HostName Property](#)

BearerToken Property

Gets and sets the OAuth 2.0 bearer token for the current user.

Syntax

object.BearerToken [= *token*]

Remarks

The **BearerToken** property specifies the OAuth 2.0 bearer token used to authenticate the user. This property is used as the default value for the **Connect** method if the token is not provided as an parameter.

Assigning a value to this property will change the current authentication method to use OAuth 2.0 if necessary.

You should only use an OAuth 2.0 authentication method if you understand the process of how to request the access token. Obtaining an bearer token requires registering your application with the mail service provider (e.g.: Microsoft or Google), getting a unique client ID associated with your application and then requesting the token using the appropriate scope for the service. Obtaining the initial token will typically involve interactive confirmation on the part of the user, requiring they grant permission to your application to access their mail account.

Your application should not store an OAuth 2.0 bearer token for later use. They have a relatively short lifespan, typically about an hour, and are designed to be used with that session. You should specify offline access as part of the OAuth 2.0 scope if necessary and store the refresh token provided by the service. The refresh token has a much longer validity period and can be used to obtain a new bearer token when needed.

If the current authentication method does not use OAuth 2.0, this property will return an empty string and you should check the value of the **Password** property to obtain the current user's password. Refer to the **AuthType** property for more information on the available authentication methods.

Data Type

String

See Also

[AuthType Property](#), [Password Property](#), [UserName Property](#), [Connect Method](#)

Blocking Property

Gets and sets the blocking state of the control.

Syntax

object.**Blocking** [= { True | False }]

Remarks

Setting the **Blocking** property determines if control actions complete synchronously or asynchronously. If set to True, then each control action, such as sending or receiving data, will return when the operation has completed or timed-out. If set to False, control actions will return immediately. If the operation would result in the control blocking, such as attempting to read data when none has been written, an error is generated. Events such as **OnConnect**, **OnDisconnect**, **OnRead** and **OnWrite** are only fired if the connection is non-blocking.

Data Type

Boolean

See Also

[IsBlocked Property](#), [IsReadable Property](#), [IsWritable Property](#)

CertificateExpires Property

Return the date and time that the server certificate expires.

Syntax

object.CertificateExpires

Remarks

The **CertificateExpires** property returns the date and time that the server certificate expires. This property will return an empty string if a secure connection has not been established with the server.

Data Type

String

See Also

[CertificateIssued Property](#), [CertificateIssuer Property](#), [CertificateStatus Property](#), [CertificateSubject Property](#), [Secure Property](#)

CertificateIssued Property

Return the date and time that the server certificate was issued.

Syntax

object.CertificateIssued

Remarks

The **CertificateIssued** property returns the date and time that the server certificate was issued. This property will return an empty string if a secure connection has not been established with the server.

Data Type

String

See Also

[CertificateExpires Property](#), [CertificateIssuer Property](#), [CertificateStatus Property](#), [CertificateSubject Property](#), [Secure Property](#)

CertificateIssuer Property

Returns information about the organization that issued the server certificate.

Syntax

object.CertificateIssuer

Remarks

The **CertificateIssuer** property returns a string that contains information about the organization that issued the server certificate. The string value is a comma separated list of tagged name and value pairs. In the nomenclature of the X.500 standard, each of these pairs are called a relative distinguished name (RDN), and when concatenated together, forms the issuer's distinguished name (DN). For example:

C=US, O="RSA Data Security, Inc.", OU=Secure Server Certification Authority

To obtain a specific value, such as the name of the issuer or the issuer's country, the application must parse the string returned by this property. Some of the common tokens used in the distinguished name are:

Name	Description
C	The ISO standard two character country code
S	The name of the state or province
L	The name of the city or locality
O	The name of the company or organization
OU	The name of the department or organizational unit
CN	The common name; with X.509 certificates, this is the domain name of the site the certificate was issued for

This property will return an empty string if a secure connection has not been established with the server.

Data Type

String

Example

The following example demonstrates how to extract the value of a relative distinguished name token:

```
Function GetCertNameValue(ByVal strValue As String, ByVal strFieldName As String)
As String
    Dim strFieldValue As String
    Dim cchValue As Integer, cchFieldName As Integer
    Dim nOffset As Integer

    GetCertNameValue = ""
    cchValue = Len(strValue)
    cchFieldName = Len(strFieldName)

    If cchValue = 0 Or cchFieldName = 0 Then
        Exit Function
    End If
```

```

nOffset = InStr(strValue, strFieldName & "=")

If nOffset > 0 Then
    '
    ' If the field name was found in the string, then
    ' remove everything to the left of the token from
    ' the string
    '
    strFieldValue = Right(strValue, cchValue - (nOffset + cchFieldName))

    '
    ' If the value is quoted, then strip off the leading
    ' quote and look for the ending quote in the string;
    ' otherwise look for the comma that marks the end of
    ' the field name/value pair
    '
    If Left(strFieldValue, 1) = Chr(34) Then
        strFieldValue = Right(strFieldValue, Len(strFieldValue) - 1)
        nOffset = InStr(strFieldValue, Chr(34))
    Else
        nOffset = InStr(strFieldValue, ",")
    End If

    '
    ' If the offset is 0, then the name/value pair is
    ' the last token in the string; otherwise, remove
    ' everything to the right of that position
    '

    If nOffset > 0 Then
        strFieldValue = Left(strFieldValue, nOffset - 1)
    End If

    GetCertNameValue = strFieldValue
End If

```

End Function

This function could then be used to return the name of the company who issued the server certificate:

```

Dim strIssuer As String
Dim strCompanyName As String

strIssuer = PopClient1.CertificateIssuer
If Len(strIssuer) = 0 Then
    MsgBox "A secure connection has not been established"
Else
    strCompanyName = GetCertNameValue(strIssuer, "O")
    MsgBox "This certificate was issued by " & strCompanyName
End If

```

See Also

[CertificateExpires Property](#), [CertificateIssued Property](#), [CertificateStatus Property](#), [CertificateSubject Property](#), [Secure Property](#)

CertificateName Property

Gets and sets the common name for the client certificate.

Syntax

object.CertificateName [= *name*]

Remarks

This property sets the common name or friendly name of the certificate that should be used to establish the connection with the server. It is only required that you set this property value if the server requires a client certificate for authentication. If this property is not set, a client certificate will not be provided to the server. If a certificate name is specified, the certificate must have a private key associated with it, otherwise the connection attempt will fail because the control will be unable to create a security context for the session.

Certificates may be installed and viewed on the local system using the Certificate Manager that is included with the Windows operating system. For more information, refer to the documentation for the Microsoft Management Console.

Data Type

String

See Also

[CertificateStore Property](#), [Secure Property](#)

CertificatePassword Property

Gets and sets the password associated with the client certificate.

Syntax

object.CertificatePassword [= *password*]

Remarks

This property sets the password that should be used to access a certificate in the specified certificate store. It is only required when the **CertificateStore** property specifies a file that contains a certificate and private key in PKCS #12 format.

Data Type

String

See Also

[CertificateName Property](#), [CertificateStore Property](#), [Secure Property](#)

CertificateStatus Property

Return the status of the server certificate.

Syntax

`object.CertificateStatus`

Remarks

The **CertificateStatus** property returns an integer value which identifies the status of the server certificate. This property may return one of the following values:

Value	Description
stCertificateNone	No certificate information is available. A secure connection was not established with the server.
stCertificateValid	The certificate is valid.
stCertificateNoMatch	The certificate is valid, however the domain name specified in the certificate does not match the domain name of the site that the client has connected to. This is typically the case if the HostAddress property is used rather than the HostName property. It is recommended that the client examine the CertificateSubject property to determine the domain name of the site that the certificate was issued for.
stCertificateExpired	The certificate has expired and is no longer valid. The client can examine the CertificateExpires property to determine when the certificate expired.
stCertificateRevoked	The certificate has been revoked and is no longer valid. It is recommended that the client application immediately terminate the connection if this status is returned.
stCertificateUntrusted	The certificate has not been issued by a trusted authority, or the certificate is not trusted on the local host. It is recommended that the client application immediately terminate the connection if this status is returned.
stCertificateInvalid	The certificate is invalid. This typically indicates that the internal structure of the certificate is damaged. It is recommended that the client application immediately terminate the connection if this status is returned.

This property value should be checked after the connection to the server has completed, but prior to beginning a transaction. If a secure connection has not been established, this property will return a value of zero.

Data Type

Integer (Int32)

Example

The following example establishes a secure connection to a server:

,

```

' Initialize the control properties
,

PopClient1.HostName = strHostName
PopClient1.Secure = True

nError = PopClient1.Connect()
If nError > 0 Then
    MsgBox "Unable to connect to server " & strHostName, vbExclamation
    Exit Sub
End If

If PopClient1.CertificateStatus <> stCertificateValid Then
    nResult = MsgBox("The server certificate could not be validated" & vbCrLf & _
        "Are you sure you wish to continue?", vbYesNo)

    If nResult = vbNo Then
        PopClient1.Disconnect
        Exit Sub
    End If
End If

PopClient1.Disconnect

```

See Also

[CertificateExpires Property](#), [CertificateIssued Property](#), [CertificateIssuer Property](#), [CertificateSubject Property](#), [Secure Property](#)

CertificateStore Property

Gets and sets the name of the client certificate store or file.

Syntax

object.CertificateStore [= *store*]

Remarks

This property sets the name of the certificate store that contains the client certificate that should be used when establishing a secure connection with the server. The certificate may either be stored in the registry or in a file. If the certificate is stored in the registry, then this property should be set to one of the following predefined values:

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. If a certificate store is not specified, this is the default value that is used.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

In most cases the client certificate will be installed in the user's personal certificate store, and therefore it is not necessary to set this property value because that is the default location that will be used to search for the certificate. This property is only used if the **CertificateName** property is also set to a valid certificate name.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU" for the current user, or "HKLM" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, it will default to the certificate store for the current user.

This property may also be used to specify a file that contains the client certificate. In this case, the property should specify the full path to the file and must contain both the certificate and private key in PKCS #12 format. If the file is protected by a password, the **CertificatePassword** property must also be set to specify the password.

Data Type

String

See Also

[CertificateName Property](#), [CertificatePassword Property](#), [Secure Property](#)

CertificateSubject Property

Returns information about the organization that the server certificate was issued to.

Syntax

`object.CertificateSubject`

Remarks

The **CertificateSubject** property returns a string that contains information about the organization that the server certificate was issued for. The string value is a comma separated list of tagged name and value pairs. In the nomenclature of the X.500 standard, each of these pairs are called a relative distinguished name (RDN), and when concatenated together, forms the subject's distinguished name (DN). For example:

C=US, O="RSA Data Security, Inc.", OU=Secure Server Certification Authority

To obtain a specific value, such as the name of the subject's company or country, the application must parse the string returned by this property. Some of the common tokens used in the distinguished name are:

Name	Description
C	The ISO standard two character country code
S	The name of the state or province
L	The name of the city or locality
O	The name of the company or organization
OU	The name of the department or organizational unit
CN	The common name; with X.509 certificates, this is the domain name of the site the certificate was issued for

This property will return an empty string if a secure connection has not been established with the server.

Data Type

String

Example

The following example demonstrates how to extract the value of a relative distinguished name token:

```
Function GetCertNameValue(ByVal strValue As String, ByVal strFieldName As String)
As String
    Dim strFieldValue As String
    Dim cchValue As Integer, cchFieldName As Integer
    Dim nOffset As Integer

    GetCertNameValue = ""
    cchValue = Len(strValue)
    cchFieldName = Len(strFieldName)

    If cchValue = 0 Or cchFieldName = 0 Then
        Exit Function
    End If
```

```

nOffset = InStr(strValue, strFieldName & "=")

If nOffset > 0 Then
    '
    ' If the field name was found in the string, then
    ' remove everything to the left of the token from
    ' the string
    '
    strFieldValue = Right(strValue, cchValue - (nOffset + cchFieldName))

    '
    ' If the value is quoted, then strip off the leading
    ' quote and look for the ending quote in the string;
    ' otherwise look for the comma that marks the end of
    ' the field name/value pair
    '

    If Left(strFieldValue, 1) = Chr(34) Then
        strFieldValue = Right(strFieldValue, Len(strFieldValue) - 1)
        nOffset = InStr(strFieldValue, Chr(34))
    Else
        nOffset = InStr(strFieldValue, ",")
    End If

    '
    ' If the offset is 0, then the name/value pair is
    ' the last token in the string; otherwise, remove
    ' everything to the right of that position
    '

    If nOffset > 0 Then
        strFieldValue = Left(strFieldValue, nOffset - 1)
    End If

    GetCertNameValue = strFieldValue
End If

```

End Function

This function could then be used to return the domain name that the server certificate was issued for:

```

Dim strSubject As String
Dim strDomainName As String

strSubject = PopClient1.CertificateSubject
If Len(strSubject) = 0 Then
    MsgBox "A secure connection has not been established"
Else
    strDomainName = GetCertNameValue(strSubject, "CN")
    MsgBox "This certificate was issued for " & strDomainName
End If

```

See Also

[CertificateExpires Property](#), [CertificateIssued Property](#), [CertificateIssuer Property](#), [CertificateStatus Property](#), [Secure Property](#)

CertificateUser Property

Gets and sets the user that owns the client certificate.

Syntax

object.CertificateUser [= *username*]

Remarks

This property sets the name of the user that owns the client certificate that will be used to establish a secure connection with the server. If this property is not set, the certificate store for the current user will be used when searching for the certificate. If this property is used to specify another user, the process must have the appropriate permission to access the registry location that contains the client certificate. On Windows Vista and later versions of the operating system, this requires that the process run with elevated privileges.

Data Type

String

See Also

[CertificateName Property](#), [CertificateStore Property](#), [Secure Property](#)

CipherStrength Property

Return the length of the key used by the encryption algorithm.

Syntax

object.CipherStrength

Remarks

The **CipherStrength** property returns the number of bits in the key used to encrypt the secure data stream. Common values returned by this property are 128 and 256. A key length of 40-bits or 56-bits is considered to be insecure, and subject to brute force attacks. 128-bit and 256-bit keys are considered secure. If this property returns a value of 0, this means that a secure connection has not been established with the server.

Data Type

Integer (Int32)

See Also

[HashStrength Property](#), [Secure Property](#), [SecureCipher Property](#), [SecureHash Property](#), [SecureKeyExchange Property](#), [SecureProtocol Property](#)

HashStrength Property

Return the length of the message digest that was selected.

Syntax

object.HashStrength

Remarks

The **HashStrength** property returns the number of bits used in the message digest (hash) that was selected. Common values returned by this property are 128 and 160. If this property returns a value of 0, this means that a secure connection has not been established with the server.

Data Type

Integer (Int32)

See Also

[CipherStrength Property](#), [Secure Property](#), [SecureCipher Property](#), [SecureHash Property](#), [SecureKeyExchange Property](#), [SecureProtocol Property](#)

HeaderField Property

Gets and sets the current header field name.

Syntax

object.HeaderField [= *header*]

Remarks

The **HeaderField** property returns the name of the current header field. Setting this property causes the control to determine if that header field exists, and if it does, to update the **HeaderValue** property with its value. This property can be used to obtain the value of any header in the current message.

Note that the server must support the XTND XLST command in order to retrieve the header value. If the command is not supported, the **HeaderValue** property will return an empty string.

Data Type

String

See Also

[HeaderValue Property](#), [Message Property](#), [MessageUID Property](#)

HeaderValue Property

Return the value of the current header field.

Syntax

object.HeaderValue

Remarks

The **HeaderValue** property returns the value of the header field specified by the **HeaderField** property. This property can be used to obtain the value of any header in the current message.

Note that the server must support the XTND XLST command in order to retrieve the header value. If the command is not supported, the **HeaderValue** property will return an empty string.

Data Type

String

See Also

[HeaderField Property](#), [Message Property](#), [MessageUID Property](#)

HostAddress Property

Gets and sets the IP address of the server.

Syntax

object.HostAddress [= *ipaddress*]

Remarks

The **HostAddress** property can be used to set the IP address for a server that you wish to communicate with. If the address is valid and matches an entry in the host table, the **HostName** property will be changed to match the address.

Data Type

String

See Also

[AutoResolve Property](#), [HostName Property](#)

HostName Property

Gets and sets the name of the server.

Syntax

object.HostName [= *hostname*]

Remarks

The **HostName** property should be set to the name of the server that you wish to communicate with. If the name is found in the host table, the **HostAddress** property is updated to reflect the IP address of the host.

Note that it is legal to assign an IP address to this property, but it is not legal to assign a host name to the **HostAddress** property.

Data Type

String

See Also

[AutoResolve Property](#), [HostAddress Property](#)

IsBlocked Property

Return if the control is blocked performing an operation.

Syntax

object.IsBlocked

Remarks

The **IsBlocked** property returns True if the specified control is blocked performing an operation. Because the Windows Sockets API only permits one blocking operation per thread of execution, this property should be checked before starting any blocking operation.

Note that this property will return True if there is *any* blocking operation being performed by the application, regardless if the specified control is responsible for the blocking operation or not.

Data Type

Boolean

See Also

[Blocking Property](#), [LastError Property](#)

IsConnected Property

Determine if the control is connected to a server.

Syntax

object.**IsConnected**

Remarks

The **IsConnected** read-only property is set to a value of true if the control is connected with a server, otherwise the property has a value of false.

Data Type

Boolean

IsInitialized Property

Determine if the control has been initialized.

Syntax

object.IsInitialized

Remarks

The **IsInitialized** property is used to determine if the current instance of the control has been initialized properly. Normally this is done automatically when the control is loaded, however there are circumstances where the control may not be able to initialize itself. If this property returns **False**, the application must call the **Initialize** method to initialize the control before performing any other operation.

The most common reason that the control may not initialize correctly is that no valid development or runtime license key can be found or the license key that was provided is invalid. It may also indicate a problem with the system configuration or user access rights, such as not being able to load the required networking libraries or not being able to access the system registry.

Data Type

Boolean

See Also

[Initialize Method](#)

IsReadable Property

Return if data can be read from the server without blocking.

Syntax

object.IsReadable

Remarks

The **IsReadable** property returns True if data can be read from the server without blocking. For non-blocking connections, this property can be checked before the application attempts to read the data, preventing an error.

Data Type

Boolean

See Also

[IsConnected Property](#), [Read Method](#), [OnRead Event](#)

IsWritable Property

Return if data can be sent to the server without blocking.

Syntax

object.IsWritable

Remarks

The **IsWritable** property returns True if data can be written without blocking. For non-blocking connections, this property can be checked before the application attempts to send data to the server, preventing an error.

If the **IsWritable** property returns False, this means that the application cannot write to the socket at that time. However, if the property returns True, this does not guarantee that you will be able to send data without an error. The next operation may result in an **stErrorOperationWouldBlock** or **stErrorOperationInProgress** error. The application must treat these errors as recoverable, and should be prepared to retry operations that result in them.

Data Type

Boolean

See Also

[IsReadable Property](#), [Write Method](#), [OnWrite Event](#)

LastError Property

Gets and sets the last error that occurred on the control.

Syntax

object.LastError [= *value*]

Remarks

The **LastError** property can be read to determine the last error that occurred for this control. If a value is assigned to this property, it must either be zero to clear the error or a valid error code for the control.

Data Type

Integer (Int32)

See Also

[LastErrorString Property](#), [OnError Event](#)

LastErrorString Property

Return a description of the last error to occur.

Syntax

object.LastErrorString

Remarks

The **LastErrorString** property returns a description of the last error that occurred. This can be used to display a meaningful error message to a user, rather than just the numeric value returned by the **LastError** property.

Data Type

String

See Also

[LastError Property](#), [OnError Event](#)

LastMessage Property

Return the number of the last message available on the server.

Syntax

object.LastMessage

Remarks

The **LastMessage** property returns the last message available on the server. Note that unlike the **MessageCount** property, this value remains constant even when a message is deleted.

Data Type

Integer (Int32)

See Also

[Message Property](#), [MessageCount Property](#), [MessageSize Property](#)

MailboxSize Property

Return the size of the current mailbox.

Syntax

object.MailboxSize

Remarks

The **MailboxSize** property returns the combined size in bytes of all of the available messages in the current mailbox. Note that as messages are deleted from the mailbox, this property value will decrease.

Data Type

Integer (Int32)

See Also

[Message Property](#), [MessageCount Property](#), [MessageSize Property](#)

Message Property

Gets and sets the current message number.

Syntax

object.**Message** [= *value*]

Remarks

The **Message** property sets or returns the message number for the currently selected mailbox. Message numbers range from 1 through the number of messages available on the server, as returned by the **MessageCount** property. Setting the **Message** property to an invalid message number will generate an error.

Data Type

Integer (Int32)

See Also

[MessageCount Property](#), [MessageSize Property](#)

MessageCount Property

Return the number of messages available in the current mailbox.

Syntax

object.MessageCount

Remarks

The **MessageCount** property returns the number of messages available to be retrieved from the currently selected mailbox.

Data Type

Integer (Int32)

See Also

[Message Property](#), [MessageSize Property](#), [MessageUID Property](#), [GetMessage Method](#)

MessageFrom Property

Return the address of the user who sent the message.

Syntax

object.MessageFrom

Remarks

The **MessageFrom** property returns the address of the user who sent the current message. This property uses either the XSENDER or the XTND XLST command in order to determine who the sender is. The XSENDER command returns an authenticated address, as used with the Netscape SMTP authentication method. If this command is not supported, or the sender's address was not authenticated, then the XTND XLST command is used to return the value of the "From" header field in the message. If this command is not supported by the server, the method will attempt to retrieve the entire message header and return the value for the specified header field. This enables an application to use this property even if the server does not support command extensions.

Data Type

String

See Also

[Message Property](#), [MessageCount Property](#), [MessageSize Property](#)

MessageSize Property

Return the size of the current message in bytes.

Syntax

object.MessageSize

Remarks

The **MessageSize** property returns the size of the current message in bytes. The size includes the header and body portion of the message.

Data Type

Integer (Int32)

See Also

[Message Property](#), [MessageCount Property](#), [MessageUID Property](#)

MessageUID Property

Return the unique ID for the current message on the mail server.

Syntax

object.MessageUID

Remarks

The **MessageID** property returns a string which uniquely identifies the message on the server. The identifier is assigned by the mail server, and retains the same value across multiple client sessions. This value is typically used when the client wants to leave a message on the mail server, but does not wish to retrieve the message contents multiple times. For example, the client can store the unique ID for each message that it retrieves, but does not delete from the server. The next time that it connects to the mail server, it compares the unique ID of a message against the stored values. If there is a match, the client knows that the message has already been retrieved, and does not need to do so again.

This property requires that the server support the optional UIDL command. If the command is not supported, this property will always return an empty string. Note that the unique ID for the message is not the same as the Message-ID header field in the message itself.

Data Type

String

See Also

[Message Property](#), [MessageCount Property](#), [MessageSize Property](#)

Options Property

Gets and sets the options that are used in establishing a connection.

Syntax

object.Options [= *value*]

Remarks

The **Options** property is an integer value which specifies one or more options. The value specified for this property will be used as the default options when connecting to the server. The property value is created by using a bitwise operator with one or more of the following values:

Value	Description
popOptionNone	No additional options are specified when establishing a connection with the server. A standard, non-secure connection will be used.
popOptionLineBreak	Message data that is received from the server is read as individual lines of text terminated by a carriage return and linefeed control sequence. This option can be useful for applications that need to use the lower level network I/O functions and must process the message text on a line-by-line basis. This option is not recommended for most applications because it can have a negative impact on performance when retrieving large messages from the server.
popOptionTunnel	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
popOptionTrustedSite	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
popOptionSecureExplicit	This option specifies that a secure connection should be established with the server and requires that the server support the TLS protocol. This option initiates the secure session using the STLS command.
popOptionSecureImplicit	This option specifies the client should attempt to establish a secure connection with the server. It should only be used when the server expects an implicit TLS connection or does not implement RFC 2595 where the STLS command is used to negotiate a secure connection with the server.
popOptionSecureFallback	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.

popOptionPreferIPv6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.

Data Type

Integer (Int32)

See Also

[Secure Property](#), [Connect Method](#)

Password Property

Gets and sets the password for the current user.

Syntax

object.Password [= *password*]

Remarks

The **Password** property specifies the password used to authenticate the user. This property is used as the default value for the **Connect** method if no password is specified as an argument.

Refer to the **AuthType** property for more information on the available authentication methods. If you are using the OAuth 2.0 authentication method, this property should not be set to the user's password. Instead, you should set the **BearerToken** property to the bearer token issued by the mail service provider. Note that these access tokens can be much larger than your typical password and are only valid for a limited period of time.

You can use the **Password** property to specify an OAuth 2.0 bearer token. However, it is recommended that you use the **BearerToken** property instead of assigning it to this property. It will ensure compatibility with future versions of the control and make it clear in your code you are using a bearer token and not a password. If the **AuthType** property specifies one of the OAuth 2.0 authentication methods, this property will return the bearer token.

Data Type

String

See Also

[AuthType Property](#), [BearerToken Property](#), [UserName Property](#), [Connect Method](#)

RemotePort Property

Gets and sets the port number for a remote connection.

Syntax

object.RemotePort [= *portnumber*]

Remarks

The **RemotePort** property is used to set the port number that the control will use to establish a connection with the server.

Data Type

Integer (Int32)

See Also

[HostAddress Property](#), [HostName Property](#)

ResultCode Property

Return the result code of the previous action.

Syntax

object.ResultCode

Remarks

The **ResultCode** read-only property returns the result of the last action performed by the client. This property should be checked after the **Command** method is used to execute a command on the server to determine if the operation was successful.

If the **ResultCode** property returns a value of true, that corresponds to an OK response from the server which indicates that the command was successful. If the property returns a value of false, that corresponds to an ERR response from the server which indicates that the command failed. The **ResultString** property typically returns more detailed information as to why the command failed.

Data Type

Boolean

See Also

[ResultString Property](#), [Command Method](#), [OnCommand Event](#)

ResultString Property

Return a string describing the results of the previous action.

Syntax

object.ResultString

Remarks

The **ResultString** read-only property returns the result string from the last action taken by the client. This string is generated by the server, and typically is used to describe the result code. For example, if an error is indicated by the result code, the result string may describe the condition that caused the error.

Data Type

String

See Also

[ResultCode Property](#), [Command Method](#), [OnCommand Event](#)

Secure Property

Set or return if a connection to the server is secure.

Syntax

object.Secure [= { True | False }]

Remarks

The **Secure** property determines if a secure connection is established to the server. The default value for this property is False, which specifies that a standard connection to the server is used. To establish a secure connection, the application must set this property value to True prior to calling the **Connect** method. Once the connection has been established, the client may request files or submit queries to the server as with standard connections.

It is strongly recommended that any application that sets this property True use error handling to trap an errors that may occur. If the control is unable to initialize the security libraries, or otherwise cannot create a secure session for the client, an error will be generated when this property value is set.

Data Type

Boolean

Example

The following example establishes a secure connection to a server:

```
PopClient1.HostName = strHostName
PopClient1.RemotePort = 110
PopClient1.UserName = strUserName
PopClient1.Password = strPassword
PopClient1.Secure = True

nError = PopClient1.Connect()
If nError > 0 Then
    MsgBox "Unable to connect to server " & strHostName, vbExclamation
    Exit Sub
End If

If PopClient1.CertificateStatus <> stCertificateValid Then
    nResult = MsgBox("The server certificate could not be validated" & vbCrLf & _
        "Are you sure you wish to continue?", vbYesNo)

    If nResult = vbNo Then
        PopClient1.Disconnect
        Exit Sub
    End If
End If
```

See Also

[CertificateStatus Property](#), [Connect Method](#)

SecureCipher Property

Return the encryption algorithm used to establish the secure connection with the server.

Syntax

object.SecureCipher

Remarks

The **SecureCipher** property returns an integer value which identifies the algorithm used to encrypt the data stream. This property may return one of the following values:

Value	Description
stCipherNone	No cipher has been selected. This is not a secure connection with the server.
stCipherRC2	The RC2 block cipher was selected. This is a variable key length cipher which supports keys between 40- and 128-bits in length, in 8-bit increments.
stCipherRC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40- and 128-bits in length, in 8-bit increments.
stCipherRC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.
stCipherDES	The DES (Data Encryption Standard) block cipher was selected. This is a fixed key length cipher using 56-bit keys.
stCipherDES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively using a 168-bit key length.
stCipherDESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.
stCipherAES	The Advanced Encryption Standard cipher (also known as the Rijndael cipher) is a fixed block size cipher which use a key size of 128, 192 or 256 bits. This cipher is supported on Windows XP SP3 and later versions of the operating system.
stCipherSkipjack	The Skipjack block cipher was selected. This is a fixed key length cipher, using 80-bit keys.
stCipherBlowfish	The Blowfish block cipher was selected. This is a variable key length cipher up to 448 bits, using a 64-bit block size.

If a secure connection has not been established, this property will return a value of zero.

Data Type

Integer (Int32)

See Also

[CipherStrength Property](#), [HashStrength Property](#), [Secure Property](#), [SecureHash Property](#), [SecureKeyExchange Property](#), [SecureProtocol Property](#)

SecureHash Property

Return the message digest selected when establishing the secure connection with the server.

Syntax

object.SecureHash

Remarks

The **SecureHash** property returns an integer value which identifies the message digest algorithm that was selected when a secure connection is established. This property may return one of the following values:

Value	Description
stHashMD5	The MD5 algorithm was selected. This algorithm has been deprecated and is no longer considered to be cryptographically secure.
stHashSHA1	The SHA-1 algorithm was selected. This algorithm has been deprecated and is no longer considered to be cryptographically secure.
stHashSHA256	The SHA-256 algorithm has been selected.
stHashSHA384	The SHA-384 algorithm has been selected.
stHashSHA512	The SHA-512 algorithm has been selected.

If a secure connection has not been established, this property will return a value of zero.

Data Type

Integer (Int32)

See Also

[CipherStrength Property](#), [HashStrength Property](#), [Secure Property](#), [SecureCipher Property](#), [SecureKeyExchange Property](#), [SecureProtocol Property](#)

SecureKeyExchange Property

Return the key exchange algorithm used to establish the secure connection with the server.

Syntax

`object.SecureKeyExchange`

Remarks

The **SecureKeyExchange** property returns an integer value which identifies the key-exchange algorithm used when establishing a secure connection. This property may return one of the following values:

Value	Description
stKeyExchangeNone	No key exchange algorithm has been selected. This is not a secure connection with the server.
stKeyExchangeRSA	The RSA public key exchange algorithm has been selected.
stKeyExchangeKEA	The KEA public key exchange algorithm has been selected. This is an improved version of the Diffie-Hellman public key algorithm.
stKeyExchangeDH	The Diffie-Hellman public key exchange algorithm has been selected.
stKeyExchangeECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography. This key exchange algorithm is only supported on Windows XP SP3 and later versions of the operating system.

If a secure connection has not been established, this property will return a value of zero.

Data Type

Integer (Int32)

See Also

[CipherStrength Property](#), [HashStrength Property](#), [Secure Property](#), [SecureCipher Property](#), [SecureHash Property](#), [SecureProtocol Property](#)

SecureProtocol Property

Gets and sets the security protocol used to establish the secure connection with the server.

Syntax

object.SecureProtocol [= *protocol*]

Remarks

The **SecureProtocol** property can be used to specify the security protocol to be used when establishing a secure connection with a server. By default, the control will attempt to use TLS 1.3 to establish the connection. If TLS 1.3 is not supported, TLS 1.2 will be used. The appropriate protocol is automatically selected based on the capabilities of both the client and server.

It is recommended that you only change this property value if you fully understand the implications of doing so. Assigning a value to this property will override the default and force the control to attempt to use only the protocol specified. One or more of the following values may be used:

Value	Description
stProtocolNone	No security protocol has been selected. A secure connection has not been established.
stProtocolTLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
stProtocolTLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
stProtocolTLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
stProtocolTLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

Multiple security protocols may be specified by combining them using a bitwise Or operator. After a connection has been established, reading this property will identify the protocol that was selected to establish the connection. Attempting to set this property after a connection has been established will result in an exception being thrown. This property should only be set after setting the **Secure** property to True and before calling the **Connect** method.

Data Type

Integer (Int32)

See Also

[CipherStrength Property](#), [HashStrength Property](#), [Secure Property](#), [SecureCipher Property](#), [SecureHash Property](#), [SecureKeyExchange Property](#)

ThrowError Property

Enables or disables error handling by the application.

Syntax

object.ThrowError = { True | False }

Remarks

Error handling for methods can be performed using either return codes or exceptions, depending on the value of this property.

If the **ThrowError** property is set to False, methods will return a status value indicating success or failure. Applications should check the return value of each method and use the **LastError** and **LastErrorString** properties to determine the cause of any error.

If the **ThrowError** property is set to True, errors occurring within the control will be raised to the host application as ActiveX exceptions. In addition, the **OnError** event will fire. This allows applications to use language-specific exception handling mechanisms, such as Visual Basic error handling, instead of checking individual return values after each method call.

Even when the **ThrowError** property is set to True, the **LastError** and **LastErrorString** properties will still be updated with information about the most recent error.

If an error occurs while accessing a property value, an exception will be raised regardless of the value of the **ThrowError** property. However, the **OnError** event will not be fired for property access errors.

Data Type

Boolean

Example

The following example handles errors by checking the return code of a method:

```
PopClient1.ThrowError = False
nError = PopClient1.Connect(strHostName)

If nError > 0 Then
    MsgBox PopClient1.LastErrorString, vbExclamation
    Exit Sub
End If
```

The following example handles errors by throwing them to the container:

```
On Error Resume Next: Err.Clear

PopClient1.ThrowError = True
PopClient1.Connect strHostName

If Err.Number <> 0
    MsgBox Err.Description, vbExclamation
    Exit Sub
End If
On Error GoTo 0
```

See Also

[LastError Property](#), [LastErrorString Property](#), [OnError Event](#)

Timeout Property

Gets and sets the amount of time until a blocking operation fails.

Syntax

object.Timeout [= *seconds*]

Remarks

Setting the **Timeout** property specifies the number of seconds until a blocking operation fails and the control returns an error.

Note that the **Timeout** property also determines the amount of time the control will spend attempting to connect to a server. If a connection is not established within the given time period, the connection attempt will fail.

Data Type

Integer (Int32)

Trace Property

Enable or disable network function level logging.

Syntax

`object.Trace [= { True | False } ]`

Remarks

The **Trace** property is used to enable or disable the logging of network function calls. When enabled, each function call is logged to a file, including the function parameters, return value and error code if applicable. This facility can be enabled and disabled at run time, and the trace log file can be specified by setting the **TraceFile** property. All function calls that are being logged are appended to the trace file, if it exists. If no log file exists when tracing is enabled, the file is created.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

Data Type

Boolean

See Also

[TraceFile Property](#), [TraceFlags Property](#)

TraceFile Property

Gets and sets the name of the file to use when logging network function calls.

Syntax

`object.TraceFile [= filename ]`

Remarks

The **TraceFile** property is used to specify the name of the file that is created when logging is enabled. If this property is set to an empty string (the default value), then a file named **SocketTools.log** is created in the current user's Documents folder. It is recommended that you always specify a complete path to the log file. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

If the file exists, the output is appended to the file, otherwise the file is created. Since logging is enabled per-process, the log file is shared by all instances of the controls being used. If you create multiple instances of the control, you only need to enable logging for a single instance. Because log files can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "0x". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxx:xxxx:xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, the control is attempting to connect to a system with the IPv4 address 192.0.0.1 on port 1234.

If the log file cannot be created, or the user does not have permission to modify an existing file, the error is silently ignored and no output will be generated.

Data Type

String

See Also

TraceFlags Property

Gets and sets the network function logging flags.

Syntax

object.TraceFlags [= *flags*]

Remarks

The **TraceFlags** property is used to specify the type of information written to the trace file when socket function tracing is enabled. The following values may be used:

Value	Description
dnsTraceInfo	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
dnsTraceError	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
dnsTraceWarning	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
dnsTraceHexDump	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
dnsTraceTruncate	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.

Since logging is enabled per-process, the trace flags are shared by all instances of the control being used. If multiple controls have tracing enabled, the **TraceFlags** property should be set to the same value for each control. Changing the trace flags for any one instance of the control will affect the logging performed for all other instances used by the application.

Warnings are generated when a non-fatal error is returned by a Windows Sockets function. For example, if data is being written through the control and an error indicating that the operation would block is returned, only a warning is logged since the application simply needs to attempt to write the data at a later time.

Data Type

Integer (Int32)

See Also

[Trace Property](#), [TraceFile Property](#)

UserName Property

Gets and sets the current user name.

Syntax

object.UserName [= *username*]

Remarks

The **UserName** property specifies the user that is logging in to the server, and is required for authentication purposes. This property is used as the default value for the **Connect** method if no password is specified as an argument.

Data Type

String

See Also

[AuthType Property](#), [BearerToken Property](#), [Password Property](#), [Connect Method](#)

Version Property

Return the current version of the control.

Syntax

object.Version

Remarks

The **Version** property returns the current version of the object. This can be used by an application for validation purposes. The version returned is composed of four numbers, separated by periods. The first number is the major version number, the second number is the minor version number, the third is the build number and the fourth is the revision number.

Data Type

String

Post Office Protocol Control Methods

Method	Description
Cancel	Cancels the current blocking network operation
ChangePassword	Change the mailbox password for the current user
CloseMessage	Closes the current message
Command	Send a custom command to the server
Connect	Establish a connection with a server
DeleteMessage	Marks a message for deletion from the mailbox
Disconnect	Terminate the connection with a server
GetHeader	Returns the value of a header field from the specified message
GetHeaders	Retrieves the headers for the specified message from the server
GetMessage	Retrieve a message from the server
Initialize	Initialize the control and validate the runtime license key
OpenMessage	Open a message on the server
Read	Return data read from the server
Reset	Reset the internal state of the control
SendMessage	Submits the contents of a specified file to the mail server for delivery
StoreMessage	Retrieve a message from the server and store it in a local file
Uninitialize	Uninitialize the control and release any system resources that were allocated
Write	Write data to the server

Cancel Method

Cancels the current blocking network operation.

Syntax

object.Cancel

Parameters

None.

Return Value

None.

Remarks

The **Cancel** method cancels any blocking network operation in the current thread. This is typically used inside an event handler, causing the blocking method to return to the caller with an error indicating that the current operation was canceled. This method sets an internal flag that is periodically checked during a blocking operation, such as waiting for more data to arrive. If the current thread is not blocked at the time that this method is called, it will have no effect.

See Also

[Disconnect Method](#), [Reset Method](#), [OnCancel Event](#)

ChangePassword Method

Change the mailbox password for the current user.

Syntax

object.ChangePassword(*OldPassword*, *NewPassword*)

Parameters

OldPassword

A string which specifies the user's current mailbox password.

NewPassword

A string which specifies the user's new password. An error will be returned if the old password and the new password are the same value.

Return Value

A value of zero is returned if the operation was successful, otherwise a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **ChangePassword** method changes the password that will be used to authenticate the user. This method requires that the **UserName** property be set, but it is not required that the user be logged into the POP3 server. Once the password has been changed, the **Password** property will be updated with the new password.

Note that in order to change the user's mailbox password, the server must be running the 'poppass' service on port 106, on the same server. Because passwords are transmitted as clear text (unencrypted), this service is not considered secure and may not be available.

See Also

[Password Property](#), [UserName Property](#)

CloseMessage Method

Closes the current message.

Syntax

object.CloseMessage

Parameters

None.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **CloseMessage** method closes the current message. If there is any remaining data left to be read from the message, it will be read and discarded.

See Also

[OpenMessage Method](#), [Read Method](#)

Command Method

Send a custom command to the server.

Syntax

object.Command(Command, [Parameters], [Options])

Parameters

Command

A string which specifies the command to send. Valid commands vary based on the Internet protocol and the type of server that the client is connected to. Consult the protocol standard and/or the technical reference documentation for the server to determine what commands may be issued by a client application.

Parameters

An optional string which specifies one or more parameters to be sent along with the command. If more than one parameter is required, most Internet protocols require that they be separated by a single space character. Consult the protocol standard and/or technical reference documentation for the server to determine what parameters should be provided when issuing a specific command. If no parameters are required for the command, this argument may be omitted.

Options

A numeric value which specifies one or more options. Currently this argument is reserved and should either be omitted, or a value of zero should always be used.

Return Value

A value of zero is returned if the command was successful. Otherwise, a non-zero error code is returned which indicates the cause of the failure. To determine the result code returned by the server in response to the command, read the value of the **ResultCode** property.

Remarks

The **Command** method sends a command to the server and processes the result code sent back in response to that command. This method can be used to send custom commands to a server to take advantage of features or capabilities that may not be supported internally by the control.

See Also

[ResultCode Property](#), [ResultString Property](#), [OnCommand Event](#)

Connect Method

Establish a connection with a server.

Syntax

object.Connect([RemoteHost], [RemotePort], [UserName], [Password], [Timeout], [Options])

Parameters

RemoteHost

A string which specifies the host name or IP address of the server. If this argument is not specified, it defaults to the value of the **HostAddress** property if it is defined. Otherwise, it defaults to the value of the **HostName** property.

RemotePort

A number which specifies the port to connect to on the server. If this argument is not specified, it defaults to the value of the **RemotePort** property. A value of zero specifies that the default port number should be used. For standard connections, the default port number is 110. For secure connections, the default port number is 995. If the secure port number is specified, an implicit TLS connection will be established by default.

UserName

A string which specifies the name of the user used to authenticate access to the server. If this argument is not specified, it defaults to the value of the **UserName** property.

Password

A string which specifies the password used to authenticate the user. If you are using the OAuth 2.0 authentication method, this property should specify the bearer token provided by the mail service and not the user password. Refer to the **AuthType** property for more information about the supported authentication methods. If this argument is not specified, it defaults to the value of the **BearerToken** or **Password** property, depending on the authentication method specified.

Timeout

The number of seconds that the client will wait for a response before failing the operation. If this argument is not specified, the value of the **Timeout** property will be used as the default.

Options

A numeric value which specifies one or more options. If this argument is omitted or a value of zero is specified, a default, standard connection will be established. This argument is constructed by using a bitwise operator with any of the following values:

Value	Description
popOptionNone	No additional options are specified when establishing a connection with the server. A standard, non-secure connection will be used.
popOptionLineBreak	Message data that is received from the server is read as individual lines of text terminated by a carriage return and linefeed control sequence. This option can be useful for applications that need to use the lower level network I/O functions and must process the message text on a line-by-line basis. This option is not recommended for most applications because it can have a negative impact on performance when

	retrieving large messages from the server.
popOptionTunnel	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
popOptionTrustedSite	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
popOptionSecureExplicit	This option specifies that a secure connection should be established with the server and requires that the server support the TLS protocol. This option initiates the secure session using the STLS command.
popOptionSecureImplicit	This option specifies the client should attempt to establish a secure connection with the server. It should only be used when the server expects an implicit TLS connection or does not implement RFC 2595 where the STLS command is used to negotiate a secure connection with the server.
popOptionSecureFallback	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
popOptionPreferIPv6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.

Return Value

A value of zero is returned if the connection was successful. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

See Also

[AuthType Property](#), [HostAddress Property](#), [HostName Property](#), [Options Property](#), [RemotePort Property](#), [Disconnect Method](#), [OnConnect Event](#)

DeleteMessage Method

Marks a message for deletion from the mailbox.

Syntax

object.DeleteMessage(MessageNumber)

Parameters

MessageNumber

Number of message to delete from the server. This value must be greater than zero. The first message in the mailbox is message number one.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **DeleteMessage** method only flags the message for deletion. The message is not actually removed from the mailbox until the client disconnects from the server, however it will no longer be accessible by the client. To prevent deleted messages from actually being removed from the mailbox, call the **Reset** method.

See Also

[Reset Method](#)

Disconnect Method

Terminate the connection with a server.

Syntax

object.Disconnect

Parameters

None.

Return Value

A value of zero is returned if the connection was terminated successfully. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

This method terminates the network connection with the server.

See Also

[IsConnected Property](#), [Connect Method](#), [OnDisconnect Event](#)

GetHeader Method

Returns the value of a header field from the specified message.

Syntax

object.GetHeader(*MessageNumber*, *HeaderField*, *HeaderValue*)

Parameters

MessageNumber

Number of message to retrieve header value from. This value must be greater than zero. The first message in the mailbox is message number one.

HeaderField

A string which specifies the message header to retrieve. The colon should not be included in this string.

HeaderValue

A string variable which will contain the value of the specified message header if the method is successful.

Return Value

A value of true is returned if the header was present and could be retrieved, otherwise a value of false is returned.

Remarks

The **GetHeader** method returns the value of a header field from the specified message. This allows an application to be able to easily determine the value of a header such as the sender, or the subject of the message. Any header field, including non-standard extensions, may be returned by this method.

This method uses the XTND XLST command, which is an extension to the POP3 protocol. If this command is not supported by the server, the method will attempt to retrieve the entire message header and return the value for the specified header field. This enables an application to use this method even if the server does not support command extensions.

See Also

[HeaderField Property](#), [HeaderValue Property](#), [GetMessage Method](#)

GetHeaders Method

Retrieves the headers for the specified message from the server.

Syntax

object.GetHeaders(*MessageNumber*, *Headers*)

Parameters

MessageNumber

Number of the message to retrieve from the server. This value must be greater than zero. The last available message number is returned by the **LastMessage** property.

Headers

A string or byte array which will contain the data transferred from the server when the method returns.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **GetHeaders** method is used to retrieve an message header block from the server and copy it into a local buffer. This method will cause the current thread to block until the article transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

See Also

[GetMessage Method](#), [OpenMessage Method](#), [OnProgress Event](#)

GetMessage Method

Retrieve a message from the server.

Syntax

object.**GetMessage**(*MessageNumber*, *Message*, [*Options*])

Parameters

MessageNumber

Number of message to retrieve from the server. This value must be greater than zero. The first message in the mailbox is message number one and the last message can be determined by checking the value of the **LastMessage** property.

Message

A string or byte array which will contain the data transferred from the server when the method returns.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **GetMessage** method is used to retrieve a message from the server and copy it into a local buffer. This method will cause the current thread to block until the message transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

See Also

[DeleteMessage Method](#), [GetHeaders Method](#), [OpenMessage Method](#), [OnProgress Event](#)

Initialize Method

Initialize the control and validate the runtime license key.

Syntax

```
object.Initialize( [LicenseKey] )
```

Parameters

LicenseKey

An optional string value which specifies a runtime license key used to initialize the control. If the license key is omitted or passed as an empty string, a development license must be installed on the local system.

Return Value

A value of zero is returned if the control was initialized successfully. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

This method dynamically loads other system libraries and allocates thread local storage. In most cases, it is not necessary to call this method directly because it is automatically invoked when an instance of the control is created by the container. However, if the control is created dynamically using **CreateObject** or a similar method, this must be the first method that is called before you attempt to modify any property values or invoke other methods. Failure to initialize the control may result in subsequent errors and/or cause an exception to be raised.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the control will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the control was created.

If the control is being used within another DLL, it is important that you do not attempt to create an instance of the control or call the **Initialize** method from within the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is written in C++ and it is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for any static and global C++ objects and has the same restrictions.

Example

```
Set popClient = CreateObject("SocketTools.PopClient.12")

nError = popClient.Initialize(strLicenseKey)
If nError > 0 Then
    MsgBox "Unable to initialize SocketTools component"
End
End If
```

See Also

[IsInitialized Property](#), [Uninitialize Method](#)

OpenMessage Method

Open a message on the server.

Syntax

object.OpenMessage([*MessageNumber*], [*Options*])

Parameters

MessageNumber

Number of message to retrieve. This value must be greater than zero. The first message in the mailbox is message number one. If this argument is omitted, the current message selected by the **Message** property will be opened.

Options

An optional integer value which specifies one or more options. This argument is reserved for future use and should be omitted.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **OpenMessage** method opens a message for reading from the server. The client can read the contents of the message using the **Read** method, and once all of the data has been read, the message should be closed by calling the **CloseMessage** method.

See Also

[Message Property](#), [CloseMessage Method](#), [GetMessage Method](#), [Read Method](#)

Read Method

Return data read from the server.

Syntax

object.Read(*Buffer*, [*Length*])

Parameters

Buffer

A buffer that the data will be stored in. If the variable is a **String** then the data will be returned as a string of characters. If the data returned by the server contains UTF-8 encoded text, it will automatically be converted to standard UTF-16 Unicode text. If you wish to read the data without conversion, provide a **Byte** array as the buffer. This parameter must be passed by reference.

Length

A numeric value which specifies the number of bytes to read. Its maximum value is $2^{31}-1 = 2147483647$. This argument is required to be present for string data. If a value is specified for this argument for other permissible types of data, and it is less than number of bytes that is determined by the control, then **Length** will override the internally computed value. If the argument is omitted, then the maximum number of bytes to read is determined by the size of the buffer.

Return Value

The number of bytes actually read from the server is returned by this method. If an error occurs, a value of -1 is returned.

Remarks

The **Read** method returns data that has been read from the server, up to the number of bytes specified. If no data is available to be read, an error will be generated if the control is non-blocking mode. If the control is in blocking mode, the program will wait until data is returned by the server or the connection is closed.

See Also

[IsConnected Property](#), [IsReadable Property](#), [Write Method](#), [OnRead Event](#), [OnWrite Event](#)

Reset Method

Reset the internal state of the control.

Syntax

object.Reset

Parameters

None.

Return Value

None.

Remarks

The **Reset** method resets the internal state of the control. Property values are initialized to their internal defaults, open network connections will be closed and any handles allocated by the control will be released. Calling this method will also prevent any messages which have been marked for deletion from being removed from the mailbox.

See Also

[Cancel Method](#), [Initialize Method](#), [Uninitialize Method](#)

SendMessage Method

Submits the contents of a specified file to the mail server for delivery.

Syntax

object.SendMessage(*Message*, [*Options*])

Parameters

Message

A string or byte array which contains the message to be delivered. The To:, Cc: and Bcc: header fields will be scanned for recipient addresses, and the Bcc: line will be deleted before the message is delivered.

Options

An optional integer value which specifies one or more options. This argument is reserved for future use and should be omitted.

Return Value

A value of zero is returned if the message was submitted successfully. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **SendMessage** method submits the messages to the mail server for delivery. The message format must comply with the RFC 822 standard, with the header and body separated by a blank line, and each line terminated with carriage-return/linefeed characters.

This method will cause the current thread to block until the message transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

This method requires that the server support the XTND XMIT command. Although using this method to send mail has the advantage that the sender is authenticated (because the user must first login to the server), it is not widely supported. For general purpose mail delivery service, it is recommended that an application use the Simple Mail Transfer Protocol (SMTP).

See Also

[StoreMessage Method](#)

StoreMessage Method

Retrieve a message from the server and store it in a local file.

Syntax

object.StoreMessage(MessageNumber, FileName)

Parameters

MessageNumber

An integer that specifies the message to retrieve. This value must be greater than zero. The first message in the mailbox is message number one.

FileName

A string which specifies the file that the message will be stored in. If an empty string is passed as an argument, the message is copied to the system clipboard.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **StoreMessage** method retrieves a message from the server and stores it in a file on the local system. The contents of the message is stored as a text file, using the specified file name. This method will cause the current thread to block until the message transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

See Also

[GetMessage Method](#), [OpenMessage Method](#)

Uninitialize Method

Uninitialize the control and release any system resources that were allocated.

Syntax

object.Uninitialize

Parameters

None.

Return Value

None.

Remarks

The **Uninitialize** method terminates any connection established by the control and resets the internal state of the control. This method is not typically used because any resources that have been allocated by an instance of the control will automatically be released when it is destroyed.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the control will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the control was created. An application should only call the **Uninitialize** method if it has explicitly called the **Initialize** method.

See Also

[Initialize Method](#)

Write Method

Write data to the server.

Syntax

object.Write(*Buffer*, [*Length*])

Parameters

Buffer

A buffer variable that contains the data to be written to the server. If the variable is a **String** type, then the data will be written as a string of characters. This is the most appropriate data type to use because the server expects text data that consists of printable characters. If the string contains Unicode characters, it will be automatically converted to use standard UTF-8 encoding prior to being sent. If you wish to send the data without conversion, use a **Byte** array as the buffer instead of a **String** variable.

Length

A numeric value which specifies the number of bytes to write. Its maximum value is $2^{31}-1 = 2147483647$. If a value is specified for this argument and it is greater than the actual size of the buffer, then the **Length** argument will be ignored and the entire contents of the buffer will be written. If the argument is omitted, then the maximum number of bytes to write is determined by the size of the buffer.

Return Value

This method returns the number of bytes actually written to the server, or -1 if an error was encountered.

Remarks

The **Write** method sends the data in *buffer* to the server. If the connection is buffered, as is typically the case, the data is copied to the send buffer and control immediately returns to the program. If the control is blocking, the application will wait until the data can be sent. If the control is non-blocking and the write fails because it could not send all of the data to the server, the **OnWrite** event will be fired when the server can accept data again.

See Also

Post Office Protocol Control Events

Event	Description
OnCancel	This event occurs when a blocking operation is canceled
OnCommand	This event occurs when the server processes a command issued by the client
OnConnect	This event occurs when a connection is established
OnDisconnect	This event occurs when a connection is terminated
OnError	This event occurs when a control error occurs
OnProgress	This event occurs during data transfer
OnRead	This event occurs when data is available to be read
OnTimeout	This event occurs when a blocking operation times out

OnCancel Event

The **OnCancel** event is generated when a blocking operation is canceled.

Syntax

Sub *object_OnCancel* ([*Index As Integer*])

Remarks

This event occurs when a blocking operation on the socket, such as sending or receiving data, is canceled with the **Cancel** method. To assist in determining which operation was canceled, consult the **State** property.

See Also

[Cancel Method](#), [OnError Event](#), [OnTimeout Event](#)

OnCommand Event

The **OnCommand** event is generated when the client sends a command to the server and receives a reply indicating the results of that command.

Syntax

Sub *object_OnCommand*([*Index As Integer*], **ByVal** *ResultCode As Variant*, **ByVal** *ResultString As Variant*)

Remarks

The **OnCommand** event is generated when the client receives a reply from the server after some action has been taken. If the **ResultCode** argument has a value of true, that corresponds to an OK response from the server which indicates that the command was successful. If the argument has a value of false, that corresponds to an ERR response from the server which indicates that the command failed.

The **ResultString** argument contains the descriptive string returned by the server which describes the result. The string contents may vary depending on the type of server.

See Also

[ResultCode Property](#), [ResultString Property](#), [Command Method](#)

OnConnect Event

The **OnConnect** event is generated when a connection is established.

Syntax

Sub *object_OnConnect* ([*Index As Integer*])

Remarks

The **OnConnect** event is generated when a connection is made with a server as a result of a **Connect** method call. This event is only triggered when the **Blocking** property is set to False.

See Also

[Blocking Property](#), [Connect Method](#), [OnDisconnect Event](#), [OnWrite Event](#)

OnDisconnect Event

The **OnDisconnect** event is generated when a connection is terminated.

Syntax

Sub *object_OnDisconnect* ([*Index As Integer*])

Remarks

The **OnDisconnect** event is generated when the connection is terminated by the server. This event is only triggered when the **Blocking** property is set to False.

When the **OnDisconnect** event fires, it is possible that there may still be buffered data available to read from the server. Before disconnecting from the server, the application should attempt to read any remaining data until the **Read** method returns a value of zero, or returns an error indicating that the operation would block.

See Also

[Blocking Property](#), [IsConnected Property](#), [IsReadable Property](#), [Connect Method](#), [Disconnect Method](#), [Read Method](#), [OnConnect Event](#)

OnError Event

The **OnError** event is generated when a control error occurs.

Syntax

```
Sub object_OnError ( [Index As Integer,] ByVal ErrorCode As Variant, ByVal Description As Variant )
```

Remarks

This event occurs when an error occurs during a control action. Errors not generated by the control itself, such as errors related to the programming language or general component errors, do not trigger this event.

The ***ErrorCode*** argument specifies the last error that has occurred. If the error is network related, the error code values returned by the control correspond to those returned by the standard Windows Sockets library.

The ***Description*** argument is a string that describes the error.

See Also

[LastError Property](#), [LastErrorString Property](#), [ThrowError Property](#)

OnProgress Event

The **OnProgress** event is generated during data transfer.

Syntax

Sub *object_OnProgress* ([*Index As Integer*], **ByVal** *MessageNumber As Variant*, **ByVal** *MessageSize As Variant*, **ByVal** *MessageCopied As Variant*, **ByVal** *Percent As Variant*)

Remarks

The **OnProgress** event is generated during the transfer of data between the client and server, indicating the amount of data exchanged. For transfers of large amounts of data, this event can be used to update a progress bar or other user-interface control to provide the user with some visual feedback. The arguments to this event are:

MessageNumber

The number of the message that is being retrieved.

MessageSize

The size of the file being transferred in bytes. This value may be zero if the control cannot obtain the size of the file from the server.

MessageCopied

The number of bytes that have been transferred between the client and server.

Percent

The percentage of data that's been transferred, expressed as an integer value between 0 and 100, inclusive. If the size of the file on the server cannot be determined, this value will always be 100.

Note that this event is only generated when message data is retrieved using the **GetHeaders** or **GetMessage** method. If the client is reading the message data directly from the server using the **Read** method, the application is responsible for calculating the completion percentage and updating any user interface controls.

See Also

[GetHeaders Method](#), [GetMessage Method](#)

OnRead Event

The **OnRead** event is generated when data is available to be read.

Syntax

Sub *object_OnRead* ([*Index As Integer*])

Remarks

The **OnRead** event is generated for non-blocking sockets when data is available to be read from the server. Use the **Read** method to read the data. This event is only triggered when the **Blocking** property is set to False.

See Also

[IsReadable Property](#), [Read Method](#), [Write Method](#), [OnWrite Event](#)

OnTimeout Event

The **OnTimeout** event is fired when a blocking operation times out.

Syntax

Sub *object_OnTimeout* ([*Index As Integer*])

Remarks

The **OnTimeout** event is generated when a blocking socket operation, such as sending or receiving data, times out. To determine which operation was in progress when the timeout occurred, consult the **State** property. This event is only triggered when the **Blocking** property is set to True.

See Also

[Timeout Property](#), [OnCancel Event](#)

OnWrite Event

The **OnWrite** event is generated when data can be written to the server.

Syntax

Sub *object_OnWrite* ([*Index As Integer*])

Remarks

The **OnWrite** event is generated for non-blocking sockets when data can be written to the server after a previous attempt failed because it would cause the control to block. This event is only triggered when the **Blocking** property is set to False.

[IsWritable Property](#), [Read Method](#), [Write Method](#), [OnConnect Event](#), [OnRead Event](#)

Internet Dialer Control

Create and monitor dial-up networking connections to an Internet service provider.

Reference

- [Properties](#)
- [Methods](#)
- [Events](#)
- [Error Codes](#)

Control Information

Object Name	RasDialerCtl.Dialer
File Name	CSRASX12.OCX
Version	12.0.3024.1286
ProgID	SocketTools.Dialer.12
ClassID	5D71D87F-A6B8-4E18-B392-4DA030E629F3
Threading Model	Apartment
Help File	CSW12HLP.CHM
Dependencies	None
Standards	RFC 1055, RFC 1661

Overview

This control provides a way for client applications to connect to a server using Microsoft Windows Remote Access Services (RAS). To use this control, the dial-up networking software must be installed on the local system. For access to the Internet, the TCP/IP protocol must be installed and configured. The control may be configured to use either the SLIP or PPP protocols, depending on the requirements of the service provider. Refer to your system documentation for information about installing and configuring dial-up networking on your system.

For those applications which may be used in a mobile environment, or otherwise require remote network access, the Dialer control provides a convenient interface to this service. Connections can be established and discontinued under the direct control of the program, rather than requiring that the user execute another program before starting your application.

Requirements

The SocketTools ActiveX Edition components are self-registering controls that are compatible with any programming language that supports the Component Object Model (COM) and the ActiveX control specification. If you are using Visual Basic 6.0, Service Pack 6 (SP6) is required. We recommend installing all available updates for your development tools. Although the Visual Basic 6.0 runtime is supported on Windows 11, the IDE itself is no longer officially supported by Microsoft. Legacy IDEs and compilers may also require elevated (administrator) privileges to run properly.

The ActiveX controls are supported on Windows 7, Windows Server 2008 R2, and later versions of both desktop and server editions of Windows. For Windows 7, Service Pack 1 (SP1) is the minimum requirement. For Windows 8 systems, the 8.1 update must be installed. On ARM-based platforms, the

minimum supported version is Windows 10 build 1709.

SocketTools includes components for both 32-bit (x86) and 64-bit (x64) Windows platforms. All modern versions of Windows are 64-bit, but we continue to include 32-bit components for compatibility with legacy development tools such as Visual Basic 6.0. We also provide native ARM64 ActiveX controls for systems running Windows on ARM. Note that 32-bit applications on ARM run using x86 emulation, and Microsoft no longer supports native ARM32 applications.

If you are using VBScript, Visual Basic for Applications (VBA), or another scripting environment on an ARM-based system, be aware that 64-bit hosts will require ARM64 components, while 32-bit hosts will use x86 components under emulation. This includes applications created with Visual Basic 6.0. To reduce deployment complexity and avoid confusion, SocketTools does not include ARM32 ActiveX controls in its standard redistribution packages but they are available on request for legacy or specialized scenarios.

Distribution

When you distribute an application that uses this control, you can either install the file in the same folder as your application executable or as a shared component in the appropriate system folder. If you install the control in the system folder, it is important that you distribute the correct version for the target platform and it must be registered. If you install the control in the same folder as your executable, it is recommended that you use registration-free activation or COM redirection to ensure that the correct version of the control is loaded by the application.

Internet Dialer Control Properties

Property	Description
AreaCode	Gets and sets the area code for the current phonebook entry
AutoConnect	Automatically detect connections established by another process
AutoDial	Determine if autodialing has been enabled on the local system
AutoDisconnect	Automatically disconnect from the server when the control is unloaded
Available	Determine if the Remote Access Service is available
Blocking	Gets and sets the blocking state of the control
BytesIn	Returns the number of bytes that have been received by the dial-up networking device
BytesOut	Returns the number of bytes that have been transmitted by the dial-up networking device
Callback	Specifies that the server should call the system back
CallbackNumber	Specifies the telephone number for the server to call back on
Connection	Return the handle for the specified dial-up networking session
Connections	Return the number of active dial-up networking sessions
ConnectSpeed	Returns the line speed for the current dial-up networking connection
CountryCode	Gets and sets the country code for the current phonebook entry
CountryName	Gets and sets the country name for the current phonebook entry
DefaultGateway	Set the default route for IP packets through the dial-up adapter
DeviceCount	Returns the number of dial-up networking devices available
DeviceEntry	Return the name of the specified device entry
DeviceName	Gets and sets the device name for the current dial-up networking connection
DeviceType	Gets and sets the device type for the current dial-up networking connection
DynamicAddress	Configure the current phonebook entry to use a dynamic IP address
DynamicNameServers	Configure the current phonebook entry to use dynamic nameservers
FramingProtocol	Gets and sets the framing protocol for the current phonebook entry
InternetAddress	Return the IP address assigned to the current dial-up networking session
Interval	Gets and sets the interval at which the connection is monitored
IpHeaderCompression	Configure the current phonebook entry to enable IP header compression
IsConnected	Determine if the control is connected to a service provider
IsInitialized	Determine if the control has been initialized
LastError	Gets and sets the last error that occurred on the control
LastErrorString	Return a description of the last error that occurred
LcpExtensions	Configure the current phonebook entry to use PPP LCP extensions
LocalNumber	Gets and sets the local phone number specified in the phonebook entry
ModemLights	Enable or disable the dial-up networking system tray icon
ModemSpeaker	Enable or disable the modem speaker

NameServer	Gets and sets the IP addresses of the nameservers assigned to the current phonebook entry
NetworkLogon	Configure the current phonebook entry to logon to the network
NetworkProtocol	Gets and sets the network protocol for the current phonebook entry
Password	The password required to establish a connection with the server
PhoneBook	Sets the file name of the Remote Access phone book to use
PhoneBookEntries	Return the number of entries in the current phone book
PhoneBookEntry	Return the name for the specified phone book entry
PhoneEntry	Specify the phone book entry to use to establish a connection with a server
PhoneNumber	Specifies the telephone number of the server
RequireEncryption	Configure the current phonebook entry to require secure authentication
ScriptFile	Gets and sets the name of the script file for the current phonebook entry
ServerAddress	Return the IP address of the dial-up networking server
SoftwareCompression	Configure the current phonebook entry to negotiate software compression
Status	Return the current status of the control
Terminal	Determine if a terminal window is displayed during the connection process
ThrowError	Enables or disables error handling by the application
Timeout	Gets and sets the number of seconds until a connection attempt fails
UserDomain	Specifies the NT domain on which user authentication is to occur
UserName	Set the user name that is required to establish a connection with the server
UserPhoneBook	Returns the name of the default user phonebook
Version	Return the current version of the control

AreaCode Property

Gets and sets the area code for the current phonebook entry.

Syntax

```
[form].object.AreaCode [= areacode ]
```

Remarks

The **AreaCode** property is used to set or return the current phonebook entry's area code. If no area code has been specified, then this property will return an empty string. The value of this property is ignored unless the **CountryCode** property is also set to a valid country code.

Data Type

String

See Also

[CountryCode Property](#), [CountryName Property](#), [LoadEntry Method](#), [SaveEntry Method](#)

AutoConnect Property

Automatically detect connections established by another process.

Syntax

object.AutoConnect = { True | False }

Remarks

The **AutoConnect** property determines if the control automatically detects if a connection has been established by another process. When enabled, the control will periodically check for any connections that have been established. The **Interval** property controls the frequency in which the control performs this check.

If the control detects that a connection has been made, it will immediately fire the **OnConnect** event, followed by the **OnStatus** event, to indicate that a connection has been established. The control then begins to monitor that connection as usual, until that connection is dropped or the control is unloaded.

To periodically check to see if a connection has been established by another process without using the **AutoConnect** property, read the value of the **Connections** property, which returns the number of active dial-up networking connections. A value greater than zero indicates that a dial-up networking connection has been established.

If there are multiple dial-up networking devices on the system, it may be possible for more than one connection to be active at a time. If this is the case, setting the **AutoConnect** property to True will cause the control to inherit the first active connection. To manage multiple dial-up connections, use the **Connection** property array to enumerate the available connections and set the **Handle** property to take control of a specific session.

Data Type

Boolean

See Also

[AutoDisconnect Property](#), [Connection Property](#), [Connections Property](#), [IsConnected Property](#), [Connect Method](#), [Disconnect Method](#), [Interval Property](#), [OnConnect Event](#), [OnDisconnect Event](#), [OnStatus Event](#)

AutoDial Property

Determine if autodialing has been enabled on the local system.

Syntax

[*form*].*object*.**AutoDial** [= { True | False }]

Remarks

The **AutoDial** property can be used to determine if autodialing is enabled or disabled on the current system. When autodialing is enabled and an application attempts to establish a connection over the Internet, a dialog box will be displayed asking the user if they want to connect to their default service provider. This property will return True if autodialing is currently enabled, or False if it has been disabled.

Setting the **AutoDial** property allows an application to change the autodial settings for the current user. Setting the property value to True specifies that you wish to enable autodialing, and the system will prompt the user to establish a dial-up connection when necessary. Setting the property to False disables autodialing, and prevents the system from prompting the user. This can be beneficial if your application needs to run in an unattended mode. If you change the autodial settings for the user, it is recommended that you restore them to their original value before the application terminates.

This property can only be changed by applications running under Windows 98, Windows NT 4.0 and later versions. If the autodial settings cannot be changed by the current user, an error will be generated.

Data Type

Boolean

AutoDisconnect Property

Automatically disconnect from the server when the control is unloaded.

Syntax

object.AutoDisconnect = { True | False }

Remarks

The **AutoDisconnect** property determines if the control should automatically disconnect from a server when the control is unloaded, typically when the application terminates. The default value for this property is True.

If a dial-up connection was already established at the time the control was loaded, this property will be reset to False, preventing it from automatically disconnecting from the host when it is unloaded. Therefore, to always force the control to automatically terminate a connection when it is unloaded, you must explicitly set the property value to True in your application.

Data Type

Boolean

See Also

[AutoConnect Property](#), [IsConnected Property](#), [Connect Method](#), [Disconnect Method](#)

Available Property

Determine if the Remote Access Service is available.

Syntax

object.Available

Remarks

This read-only property returns True if the Remote Access Service (RAS) software has been installed on the system. Note that this property does **not** indicate that the required hardware is available or that a specific protocol has been configured.

Data Type

Boolean

Blocking Property

Gets and sets the blocking state of the control.

Syntax

`[form].object.Blocking` [= { True | False }]

Remarks

The **Blocking** property determines how the control establishes a dial-up connection. If set to True, the control will wait until a connection has been established or the connection attempt fails before returning control to the application. If set to False, the control will begin the connection process and return control immediately to the application. For a non-blocking connection, the application should monitor the **OnStatus** event to determine the progress of the connection attempt. The default value for this property is False.

Data Type

Boolean

See Also

[IsConnected Property](#), [Status Property](#), [Connect Method](#), [OnStatus Event](#)

BytesIn Property

Returns the number of bytes that have been received by the dial-up networking device.

Syntax

`[form].object.BytesIn`

Remarks

The **BytesIn** property returns the number of bytes that have been received by the dial-up networking device. If the control is unable to determine the number of bytes received, it will return a value of zero.

This property is only supported with applications running under Windows 98 and Windows 2000. A general purpose application designed to run on all of the common Windows platforms should expect that this property may return zero as a value.

Data Type

Integer (Int32)

See Also

[BytesOut Property](#), [ConnectSpeed Property](#)

BytesOut Property

Returns the number of bytes that have been transmitted by the dial-up networking device.

Syntax

`[form].object.BytesOut`

Remarks

The **BytesOut** property returns the number of bytes that have been transmitted by the dial-up networking device. If the control is unable to determine the number of bytes transmitted, it will return a value of zero.

This property is only supported with applications running under Windows 98 and Windows 2000. A general purpose application designed to run on all of the common Windows platforms should expect that this property may return zero as a value.

Data Type

Integer (Int32)

See Also

[BytesIn Property](#), [ConnectSpeed Property](#)

Callback Property

Specifies that the server should call the system back.

Syntax

[*form*.]*object*.**Callback** [= { True | False }]

Remarks

Setting the **Callback** property specifies that the server should call the user back at the telephone number specified by the **CallbackNumber** property. This property is ignored unless the user has "Set By Caller" callback permission on the server.

Data Type

Boolean

See Also

[CallbackNumber Property](#), [PhoneEntry Property](#), [PhoneNumber Property](#)

CallbackNumber Property

Specifies the telephone number for the server to call back on.

Syntax

`[form.]object.CallbackNumber [ = number ]`

Remarks

Setting the **CallbackNumber** property specifies that the server should call the user back at the given telephone number. This property is ignored unless the user has "Set By Caller" callback permission on the server. Assigning an asterisk to this property causes the number stored in the phone book entry to be used for callback.

Data Type

String

See Also

[Callback Property](#), [PhoneEntry Property](#), [PhoneNumber Property](#)

Connection Property

Return the handle for the specified dial-up networking session.

Syntax

`[form.]object.Connection(Index)`

Remarks

The **Connection** property array can be used to enumerate the active dial-up networking sessions on the local system. The index is zero-based, and the number of connections is returned by the **Connections** property. The property returns a long integer value which represents the handle to the session. Setting the **Handle** property to this value will cause the control to inherit the session and the control's properties will be updated with information about the connection.

Specifying an index greater than the number of available connections will generate an error.

Data Type

Integer (Int32)

See Also

[AutoConnect Property](#), [Connections Property](#), [IsConnected Property](#)

Connections Property

Return the number of active dial-up networking sessions.

Syntax

`[form.]object.Connections`

Remarks

The **Connections** property returns the number of active dial-up networking connections on the local system. A value of zero indicates that there is no dial-up networking connection. This property is used in conjunction with the **Connection** property array to enumerate the connections on the current system.

Data Type

Integer (Int32)

See Also

[AutoConnect Property](#), [Connection Property](#), [IsConnected Property](#)

ConnectSpeed Property

Returns the line speed for the current dial-up networking connection.

Syntax

`[form].object.ConnectSpeed`

Remarks

The **ConnectSpeed** property returns the speed, in bytes per second, at which the current dial-up networking device has established a connection. If the control is unable to determine the connection speed, it will return a value of zero.

This property is only supported with applications running under Windows 98, Windows NT 4.0 and later versions. A general purpose application designed to run on all of the common Windows platforms should expect that this property may return zero as a value.

Data Type

Integer (Int32)

See Also

[BytesIn Property](#), [BytesOut Property](#)

CountryCode Property

Gets and sets the country code for the current phonebook entry.

Syntax

`[form].object.CountryCode [= code ]`

Remarks

The **CountryCode** property specifies the numeric country code for the current phonebook entry. If this value is zero, then the country and area code information is not used when dialing the phone number. The country code for the United States is 1.

Data Type

Integer (Int32)

See Also

[AreaCode Property](#), [CountryName Property](#), [LoadEntry Method](#), [SaveEntry Method](#)

CountryName Property

Gets and sets the country name for the current phonebook entry.

Syntax

`[form].object.CountryName [= country ]`

Remarks

The **CountryName** property returns the name of the country associated with the country code used when dialing the current phonebook entry. If no country code has been specified, this property will return an empty string. Setting this property to the name of a country will change the current country code. If no area code has been defined, and the country code specifies the current dialing location, the **AreaCode** property will be updated to the current area code.

Data Type

String

See Also

[AreaCode Property](#), [CountryCode Property](#), [LoadEntry Method](#), [SaveEntry Method](#)

DefaultGateway Property

Set the default route for IP packets through the dial-up adapter.

Syntax

`[form].object.DefaultGateway [= { True | False } ]`

Remarks

The **DefaultGateway** property is used to determine the default route for IP packets. If set to True, then packets are routed through the dial-up networking adapter when the connection is active. The value of this property corresponds to the "Use Default Gateway" checkbox on the TCP/IP configuration dialog.

Data Type

Boolean

DeviceCount Property

Returns the number of dial-up networking devices available.

Syntax

`[form].object.DeviceCount`

Remarks

The **DeviceCount** property returns the number of dial-up networking devices available. This property can be used in conjunction with the **DeviceEntry** property array to enumerate the devices.

Data Type

Integer (Int32)

See Also

[DeviceEntry Property](#), [DeviceName Property](#), [DeviceType Property](#)

DeviceEntry Property

Return the name of the specified device entry.

Syntax

`[form].object.DeviceEntry( Index )`

Remarks

The **DeviceEntry** property array can be used in conjunction with the **DeviceCount** property to enumerate the available dial-up networking devices. Typically this is used to provide a user with a selection of dial-up devices. The device used by the current phonebook entry can be changed by setting the **DeviceName** property to one of the device entry values.

Note that you should first set the **DeviceType** property to the type of device which you wish to enumerate. The default device type is "modem", for serial analog modems or other devices which recognize the AT command set.

Data Type

String

See Also

[DeviceCount Property](#), [DeviceName Property](#), [DeviceType Property](#)

DeviceName Property

Gets and sets the device name for the current dial-up networking connection.

Syntax

[*form*.]*object*.**DeviceName** [= *devicename*]

Remarks

The **DeviceName** property returns a description of the device that the connection was established on. For example, the string "US Robotics Sportster 28000" may be returned for a modem. Note that this property value may change if the **DeviceType** property is modified. Setting this property will change the device used to establish the dial-up networking connection. Changes to this property value should be made after changes to the **DeviceType** property.

To enumerate a list of available devices for a given device type, use the **DeviceCount** property and **DeviceEntry** property array.

Data Type

String

See Also

[DeviceCount Property](#), [DeviceEntry Property](#), [DeviceType Property](#)

DeviceType Property

Gets and sets the device type for the current dial-up networking connection.

Syntax

[*form*.]**object.DeviceType** [= *devicetype*]

Remarks

The **DeviceType** property returns the type of device that the connection was established with. Setting this property will change the type of device that will be used to establish the connection. Valid device names are:

Value	Description	
rasDeviceModem	modem	An internal or external serial analog modem device, or other serial communications device which supports the AT command set
rasDeviceISDN	isdn	An ISDN terminal adapter. Note that some ISDN devices, such as the 3Com ImpactIQ are considered modem devices.
rasDeviceX25	x25	An X25 device adapter.
rasDeviceVPN	vpn	A virtual private network connection.
RasDevicePad	pad	A packet assembler/disassembler.

Because changing the device type can change the current device name, it is recommended that applications change this property value before changing the value of the **DeviceName** property.

Data Type

String

See Also

[DeviceCount Property](#), [DeviceEntry Property](#), [DeviceName Property](#)

DynamicAddress Property

Configure the current phonebook entry to use a dynamic IP address.

Syntax

`[form].object.DynamicAddress [= { True | False } ]`

Remarks

The **DynamicAddress** property determines if the current phonebook entry should use a dynamically assigned IP address. If this property is set to True, then an IP address is assigned to the dial-up adapter when the connection is established. If set to False, then the dial-up adapter IP address is set to the value of the **InternetAddress** property.

Data Type

Boolean

See Also

[DynamicNameServers Property](#), [InternetAddress Property](#)

DynamicNameServers Property

Configure the current phonebook entry to use dynamic nameservers.

Syntax

[*form*].*object*.DynamicNameServers [= { True | False }]

Remarks

The **DynamicNameServers** property determines if the current phonebook entry should use dynamically assigned nameservers. If this property is set to True, then one or more nameservers are assigned to the dial-up adapter when the connection is established. If set to False, then the dial-up adapter nameservers are set to the values specified by the **NameServer** property array.

Data Type

Boolean

See Also

[DynamicAddress Property](#), [InternetAddress Property](#), [NameServer Property](#)

FramingProtocol Property

Gets and sets the framing protocol for the current phonebook entry.

Syntax

[*form*].**object.FramingProtocol** [= *protocol*]

Remarks

The **FramingProtocol** property is used to set or return the framing protocol used for the current phonebook entry. The following values may be specified:

Value	Description
rasFramingProtocolPpp	Point-to-Point Protocol (PPP). This is the most common protocol used by Internet Service Providers (ISPs).
rasFramingProtocolSlip	Serial Line Internet Protocol (SLIP). This is a protocol commonly used when connecting to older UNIX systems.
rasFramingProtocolRas	A proprietary Microsoft protocol implemented in Windows for Workgroups 3.11 and Windows NT 3.1

Note that unless there is a specific need for the application to use SLIP or the Microsoft protocol, it is recommended that PPP always be selected as the framing protocol.

Data Type

Integer (Int32)

See Also

[NetworkProtocol Property](#)

Handle Property

Gets and sets the handle for the current dial-up networking connection.

Syntax

object.Handle [= *hrasconn*]

Remarks

The **Handle** property returns the handle to the current dial-up networking connection, or a value of zero if the control has not been used to establish a connection. Setting the value of this property to a valid handle causes the control to inherit the specified connection, and the control's properties will be updated with information about that connection. This enables an application to monitor and control a connection that was established by the user or another program.

Setting the **Handle** property to a value of zero causes the control to release the current connection, however it will not cause the dial-up networking session to terminate. To disconnect from the server, the **Disconnect** method must be called by the application. Setting the property to a non-zero value which does not specify a valid handle will generate an error.

Data Type

Integer (Int32)

See Also

[AutoConnect Property](#), [Connection Property](#), [Connections Property](#), [IsConnected Property](#)

InternetAddress Property

Return the IP address assigned to the current dial-up networking session.

Syntax

object.InternetAddress [= *ipaddress*]

Remarks

The **InternetAddress** property returns the IP address assigned to the current dial-up networking session. If no connection has been established, or the connection has not been made with a PPP server, then this property will return an empty string. If the **DynamicAddress** property is set to False, changing this property value will update the IP address assigned to the current phonebook entry.

The IP address may only be changed before a connection is established.

Data Type

String

See Also

[DynamicAddress Property](#), [ServerAddress Property](#)

Interval Property

Gets and sets the interval at which the connection is monitored.

Syntax

`[form.]object.Interval` [= *milliseconds*]

Remarks

The **Interval** property specifies the interval, in milliseconds, at which the connection is monitored by the control. The minimum value of 0 indicates that the control should not monitor the connection. The maximum interval value is 65536 milliseconds, which is slightly more than one minute. The default value is 1000, which causes the control to check the connection status every second.

Note that setting the property value to zero will prevent the control from detecting certain conditions, such as a disconnected telephone line or a modem that is turned off.

Data Type

Integer (Int32)

See Also

[OnStatus Event](#), [OnTimeout Event](#), [Timeout Property](#)

IpHeaderCompression Property

Configure the current phonebook entry to enable IP header compression.

Syntax

[*form*].*object*.DynamicAddress [= { True | False }]

Remarks

The **IpHeaderCompression** property is used to enable or disable IP header compression. If set to True, when a connection is established, RAS will negotiate with the dial-up server to use header compression. If set to False, header compression will not be negotiated. This property corresponds to the "Use IP Header Compression" checkbox on the TCP/IP configuration dialog.

Data Type

Boolean

See Also

[DynamicNameServers Property](#), [InternetAddress Property](#), [SoftwareCompression Property](#)

IsConnected Property

Determine if the control is connected to a server.

Syntax

object.IsConnected

Remarks

The read-only **IsConnected** property is used to determine if the control has connected to the server. A value of true indicates that the connection has been established.

Note that the **IsConnected** property should not be used to determine if an active dial-up networking connection has been established by another application. The property will only return True if the control has been used to establish the connection itself, or if a connection is inherited by setting either the **AutoConnect** or **Handle** properties. To determine if there are any active dial-up networking connections, check the value of the **Connections** property.

Data Type

Boolean

See Also

[AutoConnect Property](#), [AutoDisconnect Property](#), [Connection Property](#), [Connections Property](#), [PhoneEntry Property](#), [Connect Method](#), [Disconnect Method](#)

IsInitialized Property

Determine if the control has been initialized.

Syntax

object.IsInitialized

Remarks

The **IsInitialized** property is used to determine if the current instance of the control has been initialized properly. Normally this is done automatically when the control is loaded, however there are circumstances where the control may not be able to initialize itself. If this property returns **False**, the application must call the **Initialize** method to initialize the control before performing any other operation.

The most common reason that the control may not initialize correctly is that no valid development or runtime license key can be found or the license key that was provided is invalid. It may also indicate a problem with the system configuration or user access rights, such as not being able to load the required networking libraries or not being able to access the system registry.

Data Type

Boolean

See Also

[Initialize Method](#)

LastError Property

Gets and sets the last error that occurred on the control.

Syntax

object.**LastError** [= *value*]

Remarks

The **LastError** property can be read to determine the last error that occurred for this control. If a value is assigned to this property, it must either be zero (to clear the error) or a valid error code for the control.

Data Type

Integer (Int32)

See Also

[LastErrorString Property](#), [ThrowError Property](#), [OnError Event](#)

LastErrorString Property

Return a description of the last error that occurred.

Syntax

object.LastErrorString

Remarks

The **LastErrorString** property returns a string that contains a description of the last error that occurred.

Data Type

String

See Also

[LastError Property](#), [ThrowError Property](#), [OnError Event](#)

LcpExtensions Property

Configure the current phonebook entry to use PPP LCP extensions.

Syntax

`[form].object.LcpExtensions [= { True | False } ]`

Remarks

The **LcpExtensions** property determines if the PPP LCP extensions defined in RFC 1570 will be used. If the PPP framing protocol is being used for the dial-up connection, it is recommended that this property be set to True. However, some older implementations of PPP may require that this property be set to False in order to establish a connection.

Data Type

Boolean

See Also

[FramingProtocol Property](#)

LocalNumber Property

Gets and sets the local phone number specified in the phonebook entry.

Syntax

`[form].object.LocalNumber [= number ]`

Remarks

The **LocalNumber** property sets or returns the local phone number that is specified in the current phonebook entry. If the **CountryCode** property has a value of zero, then the local number is dialed to connect to the server. If the **CountryCode** property is set to a valid country code, then RAS will also use the country and area code values when dialing the phone number.

Note that this property only determines the local phone number for the phonebook entry, and can be overridden by setting the **PhoneNumber** property to a specific value.

Data Type

String

See Also

[AreaCode Property](#), [CountryCode Property](#), [CountryName Property](#), [PhoneNumber Property](#)

ModemLights Property

Enable or disable the dial-up networking system tray icon.

Syntax

`[form].object.ModemLights [= { True | False } ]`

Remarks

The **ModemLights** property determines if the dial-up networking icon in the system tray is displayed when a connection is established.

Data Type

Boolean

See Also

[ModemSpeaker Property](#)

ModemSpeaker Property

Enable or disable the modem speaker.

Syntax

`[form].object.ModemSpeaker [= { True | False } ]`

Remarks

The **ModemSpeaker** property determines if the modem speaker is enabled when dialing the server. If the property is set to False, the modem will be silent when dialing the telephone number and establishing the connection. Note that setting this property to True will not force the speaker on if the modem hardware has been configured to explicitly disable the speaker.

To disable the speaker, the modem must support changes to the speaker volume. Disabling the speaker is typically done by instructing the modem to set the speaker volume to zero.

Data Type

Boolean

See Also

[ModemLights Property](#)

NameServer Property

Gets and sets the IP addresses of the nameservers assigned to the current phonebook entry.

Syntax

`[form].object.NameServer( Index ) [= ipaddress ]`

Remarks

The **NameServer** property array is used to set or return the nameserver IP addresses assigned to the current phonebook entry. The index value may range from 0 to 3:

Index	Description
0	Primary DNS nameserver IP address
1	Alternate DNS nameserver IP address
2	Primary WINS nameserver IP address
3	Alternate WINS nameserver IP address

Setting the property array to an IP address changes the corresponding address assigned to the phonebook entry. Note that assigned nameserver addresses are only used if the **DynamicNameServers** property has been set to False. If dynamic nameservers are assigned to the session, this property array will not return those addresses, it will return empty strings.

Data Type

String

See Also

[DynamicNameServers Property](#)

NetworkLogon Property

Configure the current phonebook entry to logon to the network.

Syntax

[*form*].*object*.**NetworkLogon** [= { True | False }]

Remarks

The **NetworkLogon** property determines if RAS automatically logs on to the network after a connection has been established. This property currently has no effect under Windows NT.

Data Type

Boolean

See Also

[DynamicNameServers Property](#), [InternetAddress Property](#)

NetworkProtocol Property

Gets and sets the network protocol for the current phonebook entry.

Syntax

[*form*].**object.NetworkProtocol** [= *protocol*]

Remarks

The **NetworkProtocol** property is used to set or return the network protocol used for the current phonebook entry. The following values may be specified:

Value	Description
rasNetworkProtocolNetBEUI	Negotiate the NetBEUI protocol.
rasNetworkProtocolIpx	Negotiate the IPX protocol.
rasNetworkProtocolIp	Negotiate the TCP/IP protocol.

These values may be combined if multiple protocols should be negotiated when the connection is established. Note that unless there is a specific need for the application to use the NetBEUI or IPX protocols, it is recommended that only the TCP/IP protocol be specified.

Data Type

Integer (Int32)

See Also

[FramingProtocol Property](#)

Password Property

The password required to establish a connection with the server.

Syntax

object.Password [= *password*]

Remarks

The **Password** property specifies the password required to establish a connection with the server. Note that this may not be the same password that is used to login to the server using terminal emulation software.

Data Type

String

See Also

[UserName Property](#), [UserDomain Property](#)

PhoneBook Property

Sets the file name of the Remote Access phone book to use.

Syntax

`[form.]object.PhoneBook [= filename ]`

Remarks

The **PhoneBook** property specifies the file name of the Remote Access phone book. Setting this property to an empty string causes the default phone book to be used.

Data Type

String

See Also

[PhoneBookEntry Property](#), [PhoneBookEntries Property](#), [UserPhoneBook Property](#)

PhoneBookEntries Property

Return the number of entries in the current phone book.

Syntax

`[form.]object.PhoneBookEntries`

Remarks

The **PhoneBookEntries** property returns the number of entries in the current phone book. A value of zero indicates that no phone book entries are available.

Data Type

Integer (Int32)

See Also

[PhoneBookEntry Property](#), [PhoneEntry Property](#)

PhoneBookEntry Property

Return the name for the specified phone book entry.

Syntax

`[form.]object.PhoneBookEntry(Index)`

Remarks

The **PhoneBookEntry** property array contains a list of the entries in the current phone book, and may be used to establish a connection with a server. Specifying an index greater than the number of available entries in the phone book will generate an error.

Data Type

String

See Also

[PhoneBookEntries Property](#), [PhoneEntry Property](#)

PhoneEntry Property

Specify the phone book entry to use to establish a connection with a server.

Syntax

[*form.*]*object*.**PhoneEntry** [= *entry*]

Remarks

The **PhoneEntry** property can be used to specify a phone book entry to use to connect with a server. The entry name identifies a communications profile which includes the telephone number, callback number and domain name of the server. Setting the **PhoneEntry** property to an empty string indicates that a telephone number will be provided to establish the connection.

Data Type

String

See Also

[PhoneBookEntries Property](#), [PhoneBookEntry Property](#), [PhoneNumber Property](#), [LoadEntry Method](#)

PhoneNumber Property

Specifies the telephone number of the server.

Syntax

`[form.]object.PhoneNumber [= value ]`

Remarks

The **PhoneNumber** property specifies the telephone number of the server. If this property is not set, then the **PhoneEntry** property must be set to a valid phone book entry. If both the **PhoneNumber** and **PhoneEntry** properties are defined, the **PhoneNumber** property will override the value specified in the phone book.

Data Type

String

See Also

[PhoneEntry Property](#), [CallbackNumber Property](#)

RequireEncryption Property

Configure the current phonebook entry to require secure authentication.

Syntax

`[form].object.RequireEncryption [= { True | False } ]`

Remarks

The **RequireEncryption** property determines if encryption is required during PPP authentication. If the property is set to True, then only secure password schemes can be used to authenticate the client. If the property is set to False, the client can use the PAP plain-text authentication protocol to authenticate the client. Some older PPP implementations may require that this property be set to False in order to establish a connection.

Data Type

Boolean

ScriptFile Property

Gets and sets the name of the script file for the current phonebook entry.

Syntax

`[form].object.ScriptFile [= filename ]`

Remarks

The **ScriptFile** property specifies the name of the login script used to establish a connection with the server. This property must be set to the full pathname of the script file. If a script file is not required, then this property should be set to an empty string.

Data Type

String

See Also

[Terminal Property](#)

ServerAddress Property

Return the IP address of the dial-up networking server.

Syntax

[*form.*]object.**ServerAddress**

Remarks

The **ServerAddress** property returns the IP address of the dial-up networking server that the local host has connected to. If no connection has been established, or the connection has not been made with a PPP server, then this property will return an empty string. This property may also return an empty string if the server did not provide this information during the connection process.

Data Type

String

See Also

[InternetAddress Property](#)

SoftwareCompression Property

Configure the current phonebook entry to negotiate software compression.

Syntax

`[form].object.SoftwareCompression [= { True | False } ] ]`

Remarks

The **SoftwareCompression** property determines if data compression is negotiated during the connection. If the property is set to True, then the client will negotiate a compatible compression protocol. Software compression should only be disabled if the client is unable to establish a connection with the server.

Data Type

Boolean

See Also

[IpHeaderCompression Property](#)

Status Property

Return the current status of the control.

Syntax

object.Status

Remarks

This read-only property returns the status of the control. It may be one of the following values:

Value	Description	
-1	rasStatusUnused	No connection has been established
rasStatusOpenPort	The communications port is about to be opened	
rasStatusPortOpened	The communications port has been opened	
rasStatusConnectDevice	A device is about to be connected	
rasStatusDeviceConnected	A device has been connected successfully	
rasStatusAllDevicesConnected	All devices have been connected	
rasStatusAuthenticate	Authenticating username and password	
rasStatusAuthNotify	An authentication event has occurred	
rasStatusAuthRetry	Requesting authentication with new credentials	
rasStatusAuthCallback	The server has requested a callback number	
rasStatusAuthChangePassword	The user has requested to change the password	
rasStatusAuthProject	Registering computer on the network	
rasStatusAuthLinkSpeed	The link speed calculation phase is starting	
rasStatusAuthAck	An authentication request is being acknowledged	
rasStatusReAuthenticate	Authenticating username and password	
rasStatusAuthenticated	The user has been authenticated	
rasStatusPrepareForCallback	The line is about to be disconnected in preparation for callback	
rasStatusWaitForModemReset	The modem is resetting itself in preparation for callback	
rasStatusWaitForCallback	Waiting for callback from server	

rasStatusProjected	Protocol specific information has been negotiated
rasStatusStartAuthentication	User authentication is being initiated
rasStatusCallbackComplete	Callback completed and resuming authentication
rasStatusLogonNetwork	Logging on to the network
rasStatusSubEntryConnected	A subentry has been connected
rasStatusSubEntryDisconnected	A subentry has been disconnected
rasStatusInteractive	Initiating interactive login session
rasStatusRetryAuthentication	Retrying user authentication
rasStatusCallbackSetByCaller	Callback has been set by caller
rasStatusPasswordExpired	Password has expired
rasStatusConnected	Connected to server
rasStatusDisconnected	Disconnected from server

Data Type

Integer (Int32)

See Also

[AutoConnect Property](#), [AutoDisconnect Property](#), [Interval Property](#), [IsConnected Property](#), [OnStatus Event](#)

Terminal Property

Determine if a terminal window is displayed during the connection process.

Syntax

[*form*].*object*.**Terminal** [= *value*]

Remarks

The **Terminal** property array is used to control if a terminal window is displayed during the dial-up networking connection process. The property may be set to one of the following values:

Value	Description
No terminal window is displayed	
Terminal window is displayed before dialing	
Terminal window is displayed after dialing. Do not use if scripting has been enabled.	
Terminal window is display before and after dialing. Do not use if scripting has been enabled.	

The terminal window can be used to allow user input before and/or after the dial-up networking connection has been established. If scripting has been enabled by setting the **ScriptFile** property, no terminal window should be displayed after the connection. This is because scripting has it's own terminal implementation.

Note that this property is only supported on Windows NT 4.0 and later versions of the operating system. Displaying a terminal window also imposes several restrictions on the behavior of the control. Because of how the Remote Access Services API is implemented by Microsoft, a connection dialog will be displayed after the **Connect** method is called if the **Terminal** property is non-zero. Setting this property to a non-zero value will also disable any asynchronous event notifications. It is not recommended that you set this property unless it is absolutely necessary.

Data Type

Integer (Int32)

See Also

[ScriptFile Property](#), [Connect Method](#)

ThrowError Property

Enables or disables error handling by the application.

Syntax

object.**ThrowError** [= { True | False }]

Remarks

Error handling for methods can be performed using either return codes or exceptions, depending on the value of this property.

If the **ThrowError** property is set to False, methods will return a status value indicating success or failure. Applications should check the return value of each method and use the **LastError** and **LastErrorString** properties to determine the cause of any error.

If the **ThrowError** property is set to True, errors occurring within the control will be raised to the host application as ActiveX exceptions. In addition, the **OnError** event will fire. This allows applications to use language-specific exception handling mechanisms, such as Visual Basic error handling, instead of checking individual return values after each method call.

Even when the **ThrowError** property is set to True, the **LastError** and **LastErrorString** properties will still be updated with information about the most recent error.

If an error occurs while accessing a property value, an exception will be raised regardless of the value of the **ThrowError** property. However, the **OnError** event will not be fired for property access errors.

Data Type

Boolean

See Also

[LastError Property](#), [LastErrorString Property](#), [OnError Event](#)

Timeout Property

Gets and sets the number of seconds until a connection attempt fails.

Syntax

`[form.]object.Timeout [= seconds ]`

Remarks

This property specifies the number of seconds that the control has to establish a connection with a server. If a connection is not established within that time period, the **OnTimeout** event is fired and the control is reset. The default value for this property is 20 seconds.

Data Type

Integer (Int32)

See Also

[Interval Property](#), [OnStatus Event](#), [OnTimeout Event](#)

UserDomain Property

Specifies the NT domain on which user authentication is to occur.

Syntax

[*form.*]*object*.UserDomain [= *domain*]

Remarks

The **UserDomain** property is used to specify the NT domain on which the user name and password will be authenticated. An empty string specifies the domain in which the Remote Access server is a member. An asterisk specifies the domain stored in the phone book entry.

Data Type

String

See Also

[Password Property](#), [UserName Property](#)

UserName Property

Set the user name that is required to establish a connection with the server.

Syntax

`[form.]object.UserName [= name ]`

Remarks

The **UserName** property specifies the user that is logging into the server, and is required for authentication purposes.

Data Type

String

See Also

[Password Property](#), [UserDomain Property](#)

UserPhoneBook Property

Returns the name of the default user phonebook.

Syntax

`[form].object.UserPhoneBook`

Remarks

The **UserPhoneBook** property returns the name of the default user phonebook. The value returned depends on how the user has configured dial-up networking, specifically whether the system, user or alternate phonebook has been selected. The current phonebook can be changed by setting the **PhoneBook** property.

Note that this property always returns an empty string under Windows 98 since phonebooks are not used (entries are stored in the system registry).

Data Type

String

See Also

[PhoneBook Property](#)

Version Property

Return the current version of the control.

Syntax

object.**Version**

Remarks

The **Version** property returns the current version of the object. This can be used by an application for validation purposes.

Data Type

String

Internet Dialer Control Methods

Method	Description
Connect	Establish a connection with a server
CreateEntry	Create a new entry in the current phonebook
DeleteEntry	Delete a phonebook entry from the local system
Disconnect	Terminate the connection with a server
EditEntry	Edit an existing phonebook entry on the local system
Initialize	Initialize the component and load the Remote Access Services library
LoadEntry	Load the specified entry from the current phonebook
RenameEntry	Rename an existing phonebook entry
Reset	Resets the control state and disconnects the current session
SaveEntry	Save the specified entry to the current phonebook
Uninitialize	Uninitialize the component and unload the Remote Access Services library

Connect Method

Establish a connection with a server.

Syntax

object.Connect([EntryName])

Parameters

EntryName

An optional string value that specifies the name of the phonebook entry to use to establish the connection. If this argument is not provided, the value of the **PhoneEntry** property is used.

Return Value

A value of zero is returned if the connection was successful. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **Connect** method establishes a dial-up networking connection with a service provider using the specified phonebook entry. If this method is called without any arguments and **PhoneEntry** property has not been set, then the current values of the **PhoneNumber**, **UserName**, **UserDomain**, and **Password** properties will be used to create a temporary phonebook entry.

See Also

[Disconnect Method](#), [CallbackNumber Property](#), [Password Property](#), [PhoneEntry Property](#), [PhoneNumber Property](#), [UserName Property](#), [UserDomain Property](#)

CreateEntry Method

Create a new entry in the current phonebook.

Syntax

object.CreateEntry

Parameters

None.

Return Value

A value of zero is returned if the operation was successful, otherwise a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **CreateEntry** method displays a dialog box which allows the user to create a new phonebook entry on the system. If you do not wish to display a dialog box, use the **SaveEntry** method instead.

See Also

[DeleteEntry Method](#), [EditEntry Method](#), [RenameEntry Method](#), [SaveEntry Method](#)

DeleteEntry Method

Delete a phonebook entry from the local system.

Syntax

object.DeleteEntry([*EntryName*])

Parameters

EntryName

An optional string value which specifies specifies the phonebook entry to delete. If this argument is not provided, the value of the **PhoneEntry** property will be used.

Return Value

A value of zero is returned if the operation was successful, otherwise a non-zero error code is returned which indicates the cause of the failure.

See Also

[CreateEntry Method](#), [EditEntry Method](#), [RenameEntry Method](#)

Disconnect Method

Terminate the dial-up networking connection.

Syntax

object.Disconnect

Parameters

None.

Return Value

A value of zero is returned if the connection was terminated successfully. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

See Also

[Connect Method](#)

EditEntry Method

Edit an existing phonebook entry on the local system.

Syntax

object.EditEntry([*EntryName*])

Parameters

EntryName

An optional string value which specifies the phonebook entry to edit. If this argument is not provided, the value of the **PhoneEntry** property will be used.

Return Value

A value of zero is returned if the operation was successful, otherwise a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **EditEntry** method edits the specified entry from the local phonebook. This will cause a dialog box to be displayed from which the user can change the connection information. If you do not want to display a dialog, then use the **SaveEntry** method instead.

See Also

[CreateEntry Method](#), [DeleteEntry Method](#), [RenameEntry Method](#), [SaveEntry Method](#)

Initialize Method

Initialize the control and validate the runtime license key.

Syntax

```
object.Initialize( [LicenseKey] )
```

Parameters

LicenseKey

An optional string value which specifies a runtime license key used to initialize the control. If the license key is omitted or passed as an empty string, a development license must be installed on the local system.

Return Value

A value of zero is returned if the control was initialized successfully. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

This method dynamically loads other system libraries and allocates thread local storage. In most cases, it is not necessary to call this method directly because it is automatically invoked when an instance of the control is created by the container. However, if the control is created dynamically using **CreateObject** or a similar method, this must be the first method that is called before you attempt to modify any property values or invoke other methods. Failure to initialize the control may result in subsequent errors and/or cause an exception to be raised.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the control will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the control was created.

If the control is being used within another DLL, it is important that you do not attempt to create an instance of the control or call the **Initialize** method from within the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is written in C++ and it is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for any static and global C++ objects and has the same restrictions.

Example

```
Set rasDialer = CreateObject("SocketTools.Dialer.11")

nError = rasDialer.Initialize(strLicenseKey)
If nError > 0 Then
    MsgBox "Unable to initialize the SocketTools component"
End If
```

See Also

[IsInitialized Property](#), [Uninitialize Method](#)

LoadEntry Method

Load the specified entry from the current phonebook.

Syntax

object.LoadEntry([*EntryName*])

Parameters

EntryName

An optional string value which specifies the phonebook entry to load. If this argument is not provided, the current entry is reloaded from the phonebook, abandoning any changes that have been made.

Return Value

A value of zero is returned if the operation was successful, otherwise a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **LoadEntry** method loads the specified entry from the current phonebook and sets the control properties to match the configuration.

See Also

[PhoneBook Property](#), [PhoneEntry Property](#)

RenameEntry Method

Rename an existing phonebook entry.

Syntax

object.RenameEntry(*OldName*, *NewName*)

Parameters

OldName

A string value that specifies the name of the phonebook entry to be renamed.

NewName

A string value that specifies the new name of the phonebook entry. This name must not already exist for another connectoid in the current phonebook.

Return Value

A value of zero is returned if the operation was successful, otherwise a non-zero error code is returned which indicates the cause of the failure.

See Also

[CreateEntry Method](#), [DeleteEntry Method](#), [EditEntry Method](#)

Reset Method

Reset the internal state of the control.

Syntax

object.Reset

Parameters

None.

Return Value

None.

Remarks

The **Reset** method resets the internal state of the control. Property values are initialized to their internal defaults, active dial-up connections will be terminated and any handles allocated by the control will be released. Any property changes to the current phonebook entry will be ignored, reverting to their previous values.

See Also

[Initialize Method](#), [Uninitialize Method](#)

SaveEntry Method

Save the specified entry to the current phonebook.

Syntax

object.SaveEntry([*EntryName*])

Parameters

EntryName

An optional string value that specifies the name of phonebook entry. If this argument is not provided, the current value of the **PhoneEntry** property is used.

Return Value

A value of zero is returned if the operation was successful, otherwise a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **SaveEntry** method saves the specified entry to the current phonebook, based on the current control properties. If the entry does not exist, it will be created. If an entry by that name already exists, it will be overwritten. Note that unlike the **CreateEntry** method, this method does not display any dialogs.

See Also

[PhoneBook Property](#), [PhoneEntry Property](#), [CreateEntry Method](#), [EditEntry Method](#)

Uninitialize Method

Uninitialize the component and unload the Remote Access Services library.

Syntax

object.Uninitialize

Parameters

None.

Return Type

None.

Remarks

The **Uninitialize** method terminates any active dial-up networking connection established by the control and unloads the Remote Access Services (RAS) library. This method is not typically used because any resources that have been allocated by an instance of the control will automatically be released when it is destroyed. To prevent the connection from being terminated when the control is uninitialized, set the **AutoDisconnect** property to False or set the **Handle** property to a value of zero before calling this method.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the control will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the control was created. An application should only call the **Uninitialize** method if it has explicitly called the **Initialize** method.

See Also

[AutoDisconnect Property](#), [Handle Property](#), [Connect Method](#), [Disconnect Method](#), [Initialize Method](#)

Internet Dialer Control Events

Event	Description
OnConnect	This event occurs when a connection is established
OnDisconnect	This event occurs when a connection is terminated
OnError	This event occurs when a control error occurs
OnStatus	This event occurs when the control state changes
OnTimeout	This event occurs when the control is unable to establish a connection

OnConnect Event

The **OnConnect** event is generated when a connection is established.

Syntax

Sub *object_OnConnect* ([*Index As Integer*])

Remarks

The **OnConnect** event is generated when a successful connection has been established with the server. To monitor the progress of the connection attempt, use the **OnStatus** event.

See Also

[OnDisconnect Event](#), [OnStatus Event](#)

OnDisconnect Event

The **OnDisconnect** event is generated when a connection is terminated.

Syntax

Sub *object_OnDisconnect* ([*Index As Integer*])

Remarks

The **OnDisconnect** event is generated when the connection is terminated by the server.

See Also

[OnConnect Event](#)

OnError Event

The **OnError** event is generated when a control error occurs.

Syntax

```
Sub object_OnError ( [Index As Integer,] ByVal ErrorCode As Variant, ByVal Description As Variant )
```

Remarks

This event occurs when an error occurs during a control operation. The **OnError** event is typically fired when a method is called which results in an error, or an error occurs during the connection or authentication process.

The ***ErrorCode*** argument specifies the numeric error code. The Remote Access Services subsystem returns errors in the range of 600 to 800. These are automatically converted to 10600 through 10800 to avoid conflicts with standard error codes. For example, error 10676 corresponds to the RAS error 676, which indicates that the line is busy.

The ***Description*** argument contains a description of the error.

See Also

[LastError Property](#), [LastErrorString Property](#), [ThrowError Property](#)

OnStatus Event

The **OnStatus** event is generated when the control state changes.

Syntax

Sub *object_OnStatus* ([*Index As Integer*,] **ByVal** *State As Variant*, **ByVal** *Description As Variant*)

Remarks

This event occurs when the status of the control changes. Typically this occurs when a connection is being established with a server.

The **State** argument is a numeric code which identifies the state of the control. This is the same value as returned by the **State** property.

The **Description** argument contains a string which describes the new state. Applications may use this value to provide feedback to the user or for logging purposes.

See Also

[AutoConnect Property](#), [AutoDisconnect Property](#), [IsConnected Property](#), [Status Property](#)

OnTimeout Event

The **OnTimeout** event is generated when the control is unable to establish a connection.

Syntax

Sub *object_OnTimeout* ([*Index As Integer*])

Remarks

This event occurs when the control is unable to establish a connection with a server in the number of seconds specified by the **Timeout** property.

[Timeout Property](#)

Internet Dialer Control Errors

Value	Description
rasErrorPending	An operation is pending
rasErrorInvalidPortHandle	An invalid port handle was detected
rasErrorPortAlreadyOpen	The specified port is already open
rasErrorBufferTooSmall	The caller's buffer is too small
rasErrorWrongInfoSpecified	Incorrect information was specified
rasErrorCannotSetPortInfo	The port information cannot be set
rasErrorPortNotConnected	The specified port is not connected
rasErrorEventInvalid	An invalid event was detected
rasErrorDeviceDoesNotExist	A device was specified that does not exist
rasErrorDevicetypeDoesNotExist	A device type was specified that does not exist
rasErrorBufferInvalid	An invalid buffer was specified
rasErrorRouteNotAvailable	A route was specified that is not available
rasErrorRouteNotAllocated	A route was specified that is not allocated
rasErrorInvalidCompressionSpecified	An invalid compression was specified
rasErrorOutOfBuffers	There were insufficient buffers available
rasErrorPortNotFound	The specified port was not found
rasErrorAsyncRequestPending	An asynchronous request is pending
rasErrorAlreadyDisconnecting	The modem or other connecting device is already disconnecting
rasErrorPortNotOpen	The specified port is not open
rasErrorPortDisconnected	A connection to the remote computer could not be established
rasErrorNoEndpoints	No endpoints could be determined
rasErrorCannotOpenPhonebook	The system could not open the phone book file
rasErrorCannotLoadPhonebook	The system could not load the phone book file
rasErrorCannotFindPhonebookEntry	The system could not find the phone book entry for this connection
rasErrorCannotWritePhonebook	The system could not update the phone book file
rasErrorCorruptPhonebook	The system found invalid information in the phone book file
rasErrorCannotLoadString	A string could not be loaded
rasErrorKeyNotFound	A key could not be found
rasErrorDisconnection	The connection was terminated by the remote computer before it could be completed
rasErrorRemoteDisconnection	The connection was closed by the remote computer
rasErrorHardwareFailure	The modem or other connecting device was disconnected due to

	hardware failure
rasErrorUserDisconnection	The user disconnected the modem or other connecting device
rasErrorInvalidSize	An incorrect structure size was detected
rasErrorPortNotAvailable	The modem or other connecting device is already in use or is not configured properly
rasErrorCannotProjectClient	Your computer could not be registered on the remote network
rasErrorUnknown	There was an unknown error
rasErrorWrongDeviceAttached	The device attached to the port is not the one expected
rasErrorBadString	A string was detected that could not be converted
rasErrorRequestTimeout	The request has timed out
rasErrorCannotGetLana	No asynchronous net is available
rasErrorNetBIOSError	An error has occurred involving NetBIOS
rasErrorServerOutOfResources	The server cannot allocate NetBIOS resources needed to support the client
rasErrorNameExistsOnNet	One of your computer's NetBIOS names is already registered on the remote network
rasErrorServerGeneralNetFailure	A network adapter at the server failed
rasErrorMsgAliasNotAdded	You will not receive network message popups
rasErrorAuthInternal	There was an internal authentication error
rasErrorRestrictedLogonHours	The account is not permitted to log on at this time of day
rasErrorAcctDisabled	The account is disabled
rasErrorPasswdExpired	The password for this account has expired
rasErrorNoDialInPermission	The account does not have permission to dial in
rasErrorServerNotResponding	The remote access server is not responding
rasErrorFromDevice	The modem or other connecting device has reported an error
rasErrorUnrecognizedResponse	There was an unrecognized response from the modem or other connecting device
rasErrorMacroNotFound	A macro required by the modem or other connecting device was not found in the configuration file
rasErrorMacroNotDefined	A command or response in the configuration file refers to an undefined macro
rasErrorMessageMacroNotFound	The message macro was not found in the configuration file
rasErrorDefaultOffMacroNotFound	The configuration file contains an undefined macro
rasErrorFileCouldNotBeOpened	The configuration file could not be opened
rasErrorDevicenameTooLong	The device name in the configuration file is too long
rasErrorDevicenameNotFound	The configuration file refers to an unknown device name
rasErrorNoResponses	The configuration file contains no responses for the command

rasErrorNoCommandFound	The configuration file is missing a command
rasErrorWrongKeySpecified	There was an attempt to set a macro not listed in configuration file
rasErrorUnknownDeviceType	The configuration file refers to an unknown device type
rasErrorAllocatingMemory	The system has run out of memory
rasErrorPortNotConfigured	The modem or other connecting device is not properly configured
rasErrorDeviceNotReady	The modem or other connecting device is not functioning
rasErrorReadingIniFile	The system was unable to read the configuration file
rasErrorNoConnection	The connection was terminated
rasErrorBadUsageInIniFile	The usage parameter in the configuration file is invalid
rasErrorReadingSectionname	The system was unable to read the section name from the configuration file
rasErrorReadingDeviceType	The system was unable to read the device type from the configuration file
rasErrorReadingDeviceName	The system was unable to read the device name from the configuration file
rasErrorReadingUsage	The system was unable to read the usage from the configuration file
rasErrorReadingMaxconnectbps	The system was unable to read the maximum connection BPS rate from the configuration file
rasErrorReadingMaxcarrierbps	The system was unable to read the maximum carrier connection speed from the configuration file
rasErrorLineBusy	The phone line is busy
rasErrorVoiceAnswer	A person answered instead of a modem or other connecting device
rasErrorNoAnswer	The remote computer did not respond
rasErrorNoCarrier	The system could not detect the carrier
rasErrorNoDialtone	There was no dial tone
rasErrorInCommand	The modem or other connecting device reported a general error
rasErrorWritingSectionname	There was an error in writing the section name
rasErrorWritingDevicetype	There was an error in writing the device type
rasErrorWritingDevicename	There was an error in writing the device name
rasErrorWritingMaxconnectbps	There was an error in writing the maximum connection speed.
rasErrorWritingMaxCarrierBps	There was an error in writing the maximum carrier speed
rasErrorWritingUsage	There was an error in writing the usage
rasErrorWritingDefaultOff	There was an error in writing the default-off
rasErrorReadingDefaultOff	There was an error in reading the default-off
rasErrorEmptyIniFile	The configuration file is empty
rasErrorAuthenticationFailure	Access was denied because the username and/or password was

	invalid on the domain
rasErrorPortOrDevice	There was a hardware failure in the modem or other connecting device
rasErrorNotBinaryMacro	An internal error has occurred
rasErrorDcbNotFound	An internal error has occurred
rasErrorStateMachinesNotStarted	The state machines are not started
rasErrorStateMachinesAlreadyStarted	The state machines are already started
rasErrorPartialResponseLooping	The response looping did not complete
rasErrorUnknownResponseKey	A response keyname in the configuration file is not in the expected format
rasErrorRecvBufFull	The modem or other connecting device response caused a buffer overflow
rasErrorCmdTooLong	The expanded command in the configuration file is too long
rasErrorUnsupportedBps	The modem moved to a connection speed not supported by the COM driver
rasErrorUnexpectedResponse	Device response received when none expected
rasErrorInteractiveMode	The connection needs information from you, but the application does not allow user interaction
rasErrorBadCallbackNumber	The callback number is invalid
rasErrorInvalidAuthState	The authorization state is invalid
rasErrorWritingInitbps	An internal error has occurred
rasErrorX25Diagnostic	There was an error related to the X.25 protocol
rasErrorAcctExpired	The account has expired
rasErrorChangingPassword	There was an error changing the password on the domain
rasErrorOverrun	Serial overrun errors were detected while communicating with the modem
rasErrorRasmanCannotInitialize	A configuration error on this computer is preventing this connection
rasErrorBiplexPortNotAvailable	The two-way port is initializing, wait a few seconds and redial
rasErrorNoActiveIsdnLines	No active ISDN lines are available
rasErrorNoIsdnChannelsAvailable	No ISDN channels are available to make the call
rasErrorTooManyLineErrors	Too many errors occurred because of poor phone line quality
rasErrorIpConfiguration	The Remote Access Service IP configuration is unusable
rasErrorNoIpAddresses	No IP addresses are available in the static pool of Remote Access Service IP addresses
rasErrorPppTimeout	The connection was terminated because the remote computer did not respond in a timely manner
rasErrorPppRemoteTerminated	The connection was terminated by the remote computer

rasErrorPppNoProtocolsConfigured	A connection to the remote computer could not be established
rasErrorPppNoResponse	The remote computer did not respond
rasErrorPppInvalidPacket	Invalid data was received from the remote computer
rasErrorPhoneNumberTooLong	The phone number, including prefix and suffix, is too long
rasErrorIpxcpNoDialoutConfigured	The IPX protocol cannot dial out on the modem because this computer is not configured for dialing out
rasErrorIpxcpNoDialinConfigured	The IPX protocol cannot dial in on the modem because this computer is not configured for dialing in
rasErrorIpxcpDialoutAlreadyActive	The IPX protocol cannot be used for dialing out on more than one modem
rasErrorAccessingTcpcfgDll	Cannot access TCPCFG.DLL
rasErrorNoIpRasAdapter	The system cannot find an IP adapter
rasErrorSlipRequiresIp	SLIP cannot be used unless the IP protocol is installed
rasErrorProjectionNotComplete	Computer registration is not complete
rasErrorProtocolNotConfigured	The protocol is not configured
rasErrorPppNotConverging	Your computer and the remote computer could not agree on PPP control protocols
rasErrorPppCpRejected	A connection to the remote computer could not be completed
rasErrorPppLcpTerminated	The PPP link control protocol was terminated
rasErrorPppRequiredAddressRejected	The requested address was rejected by the server
rasErrorPppNcpTerminated	The remote computer terminated the control protocol
rasErrorPppLoopbackDetected	Loopback was detected
rasErrorPppNoAddressAssigned	The server did not assign an address
rasErrorCannotUseLogonCredentials	The authentication protocol required by the server cannot use the stored password
rasErrorTapiConfiguration	An invalid dialing rule was detected
rasErrorNoLocalEncryption	The local computer does not support the required data encryption type
rasErrorNoRemoteEncryption	The remote computer does not support the required data encryption type
rasErrorRemoteRequiresEncryption	The remote computer requires data encryption
rasErrorIpxcpNetNumberConflict	The system cannot use the IPX network number assigned by the remote computer
rasErrorInvalidSmm	An internal error has occurred
rasErrorSmmUninitialized	An internal error has occurred
rasErrorNoMacForPort	An internal error has occurred
rasErrorSmmTimeout	An internal error has occurred

rasErrorBadPhoneNumber	An invalid telephone number has been specified
rasErrorWrongModule	An internal error has occurred
rasErrorInvalidCallbackNumber	The callback number contains an invalid character
rasErrorScriptSyntax	A syntax error was encountered while processing a script
rasErrorHangupFailed	The connection could not be disconnected because it was created by the multi-protocol router
rasErrorBundleNotFound	The system could not find the multi-link bundle
rasErrorCannotDoCustomdial	The system cannot perform automated dial because this connection has a custom dialer specified
rasErrorDialAlreadyInProgress	This connection is already being dialed
rasErrorRasautoCannotInitialize	Remote Access Services could not be started automatically
rasErrorConnectionAlreadyShared	Internet Connection Sharing is already enabled on the connection
rasErrorSharingChangeFailed	An error occurred while the existing Internet Connection Sharing settings were being changed
rasErrorSharingRouterInstall	An error occurred while routing capabilities were being enabled
rasErrorShareConnectionFailed	An error occurred while Internet Connection Sharing was being enabled for the connection
rasErrorSharingPrivateInstall	An error occurred while the local network was being configured for sharing
rasErrorCannotShareConnection	Internet Connection Sharing cannot be enabled
rasErrorNoSmartCardReader	No smart card reader is installed
rasErrorSharingAddressExists	Internet Connection Sharing cannot be enabled
rasErrorNoCertificate	A certificate could not be found
rasErrorSharingMultipleAddresses	Internet Connection Sharing cannot be enabled
rasErrorFailedToEncrypt	The connection attempt failed because of failure to encrypt data
rasErrorBadAddressSpecified	The specified destination is not reachable
rasErrorConnectionReject	The remote computer rejected the connection attempt
rasErrorCongestion	The connection attempt failed because the network is busy
rasErrorIncompatible	The remote computer's network hardware is incompatible with the type of call requested
rasErrorNumberChanged	The connection attempt failed because the destination number has changed
rasErrorTempfailure	The connection attempt failed because of a temporary failure
rasErrorBlocked	The call was blocked by the remote computer
rasErrorDonotdisturb	The call could not be connected because the remote computer has invoked the Do Not Disturb feature
rasErrorOutOfOrder	The connection attempt failed because the modem on the remote

	computer is out of order
rasErrorUnableToAuthenticateServer	It was not possible to verify the identity of the server
rasErrorSmartCardRequired	To dial out using this connection you must use a smart card
rasErrorInvalidFunctionForEntry	An attempted function is not valid for this connection
rasErrorCertForEncryptionNotFound	The connection requires a certificate, and no valid certificate was found
rasErrorSharingRrasConflict	Network Address Translation must be removed before enabling Internet Connection Sharing
rasErrorSharingNoPrivateLan	Internet Connection Sharing cannot be enabled
rasErrorNoDiffUserAtLogon	You cannot dial using this connection at logon time
rasErrorNoRegCertAtLogon	You cannot dial using this connection at logon time
rasErrorOakleyNoCert	The L2TP connection attempt failed because there is no valid machine certificate on your computer for security authentication
rasErrorOakleyAuthFail	The L2TP connection attempt failed because the security layer could not authenticate the remote computer
rasErrorOakleyAttribFail	The L2TP connection attempt failed because the security layer could not negotiate compatible parameters with the remote computer
rasErrorOakleyGeneralProcessing	The L2TP connection attempt failed because the security layer encountered a processing error during initial negotiations with the remote computer
rasErrorOakleyNoPeerCert	The L2TP connection attempt failed because certificate validation on the remote computer failed
rasErrorOakleyNoPolicy	The L2TP connection attempt failed because security policy for the connection was not found
rasErrorOakleyTimedOut	The L2TP connection attempt failed because security negotiation timed out
rasErrorOakleyError	The L2TP connection attempt failed because an error occurred while negotiating security
rasErrorUnknownFramedProtocol	The Framed Protocol RADIUS attribute for this user is not PPP
rasErrorWrongTunnelType	The Tunnel Type RADIUS attribute for this user is not correct
rasErrorUnknownServiceType	The Service Type RADIUS attribute for this user is neither Framed nor Callback Framed
rasErrorConnectingDeviceNotFound	A connection to the remote computer could not be established because the modem was not found or was busy
rasErrorNoEaptlsCertificate	A certificate could not be found that can be used with this Extensible Authentication Protocol
rasErrorSharingHostAddressConflict	Internet Connection Sharing cannot be enabled
rasErrorAutomaticVpnFailed	Unable to establish the VPN connection
rasErrorValidatingServerCert	Unable to verify the digital certificate sent by the server

Remote Command Control

Execute commands on a server or establish an interactive terminal session.

Reference

- [Methods](#)
- [Events](#)
- [Error Codes](#)

Control Information

Object Name	RshClientCtl.RshClient
File Name	CSRSHX12.OCX
Version	12.0.3024.1286
ProgID	SocketTools.RshClient.12
ClassID	C4870EDE-83E6-45FA-B111-7E593EEACBF9
Threading Model	Apartment
Help File	CST12CTL.CHM
Dependencies	None
Standards	RFC 1282

Overview

The Remote Command control is used to execute a command on a server and return the output of that command to the client. This is most commonly used with UNIX based servers, although there are implementations of remote command servers for the Windows operating system. The control supports both the rcmd and rshell remote execution protocols and provides functions which can be used to search the data stream for specific sequences of characters. This makes it extremely easy to write Windows applications which serve as light-weight client interfaces to commands being executed on a UNIX server or another Windows system. The control can also be used to establish a remote terminal session using the rlogin protocol, which is similar to the Telnet protocol.

The Remote Shell (rsh/rcmd) protocol is deprecated, insecure, and should never be used. This protocol transmits user credentials and command data in plaintext, making it vulnerable to interception, spoofing, and other network-based attacks. Support for this protocol will be removed in a future release. For secure remote command execution and interactive terminal sessions, it is recommended you use the [Secure Shell](#) ActiveX control.

Requirements

The SocketTools ActiveX Edition components are self-registering controls that are compatible with any programming language that supports the Component Object Model (COM) and the ActiveX control specification. If you are using Visual Basic 6.0, Service Pack 6 (SP6) is required. We recommend installing all available updates for your development tools. Although the Visual Basic 6.0 runtime is supported on Windows 11, the IDE itself is no longer officially supported by Microsoft. Legacy IDEs

and compilers may also require elevated (administrator) privileges to run properly.

The ActiveX controls are supported on Windows 7, Windows Server 2008 R2, and later versions of both desktop and server editions of Windows. For Windows 7, Service Pack 1 (SP1) is the minimum requirement. For Windows 8 systems, the 8.1 update must be installed. On ARM-based platforms, the minimum supported version is Windows 10 build 1709.

SocketTools includes components for both 32-bit (x86) and 64-bit (x64) Windows platforms. All modern versions of Windows are 64-bit, but we continue to include 32-bit components for compatibility with legacy development tools such as Visual Basic 6.0. We also provide native ARM64 ActiveX controls for systems running Windows on ARM. Note that 32-bit applications on ARM run using x86 emulation, and Microsoft no longer supports native ARM32 applications.

If you are using VBScript, Visual Basic for Applications (VBA), or another scripting environment on an ARM-based system, be aware that 64-bit hosts will require ARM64 components, while 32-bit hosts will use x86 components under emulation. This includes applications created with Visual Basic 6.0. To reduce deployment complexity and avoid confusion, SocketTools does not include ARM32 ActiveX controls in its standard redistribution packages but they are available on request for legacy or specialized scenarios.

Distribution

When you distribute an application that uses this control, you can either install the file in the same folder as your application executable or as a shared component in the appropriate system folder. If you install the control in the system folder, it is important that you distribute the correct version for the target platform and it must be registered. If you install the control in the same folder as your executable, it is recommended that you use registration-free activation or COM redirection to ensure that the correct version of the control is loaded by the application.

Remote Command Control Properties

Property	Description
AutoResolve	Determines if host names and IP addresses are automatically resolved
Blocking	Gets and sets the blocking state of the control
CodePage	Gets and sets the code page used when reading and writing text
Command	Gets and sets the command to be executed on the server
HostAddress	Gets and sets the IP address of the server
HostName	Gets and sets the name of the server
IsBlocked	Return if the control is blocked performing an operation
IsConnected	Determine if the control is connected to a server
IsInitialized	Determine if the control has been initialized
IsReadable	Return if data can be read from the server without blocking
IsWritable	Return if data can be sent to the server without blocking
LastError	Gets and sets the last error that occurred on the control
LastErrorString	Return a description of the last error to occur
Password	Gets and sets the password for the current user
RemotePort	Gets and sets the port number for a remote connection
Terminal	Gets and sets the terminal type used by the control
ThrowError	Enables or disables error handling by the application
Timeout	Gets and sets the amount of time until a blocking operation fails
Trace	Enable or disable socket function level tracing
TraceFile	Specify the socket function trace output file
TraceFlags	Gets and sets the socket function tracing flags
UserName	Gets and sets the current user name
Version	Return the current version of the control

AutoResolve Property

Determines if host names and IP addresses are automatically resolved.

Syntax

object.AutoResolve [= { True | False }]

Remarks

Setting the **AutoResolve** property determines if the control automatically resolves host names and addresses specified by the **HostName** and **HostAddress** properties. If set to True, setting the **HostName** property will cause the control to automatically determine the corresponding IP address and set the **HostAddress** property accordingly. Likewise, setting the **HostAddress** property will cause the control to determine the host name and set the **HostName** property. Setting the property to False prevents the control from resolving host names until a connection attempt is made.

Note that setting the **HostName** or **HostAddress** property may cause the current thread to block, sometimes for several seconds, until the name or address is resolved. To prevent this behavior, set **AutoResolve** to False.

Data Type

Boolean

See Also

[HostAddress Property](#), [HostName Property](#)

Blocking Property

Gets and sets the blocking state of the control.

Syntax

object.**Blocking** [= { True | False }]

Remarks

Setting the **Blocking** property determines if control actions complete synchronously or asynchronously. If set to True, then each control action, such as sending or receiving data, will return when the operation has completed or timed-out. If set to False, control actions will return immediately. If the operation would result in the control blocking, such as attempting to read data when none has been written, an error is generated. Events such as **OnConnect**, **OnDisconnect**, **OnRead** and **OnWrite** are only fired if the connection is non-blocking.

Data Type

Boolean

See Also

[IsBlocked Property](#), [IsReadable Property](#), [IsWritable Property](#)

CodePage Property

Gets and sets the code page used when reading and writing text.

Syntax

object.CodePage [= *value*]

Remarks

The **CodePage** property is an integer value which specifies how strings are encoded when data is sent or received. Any valid code page identifier may be specified. Some common values are:

Value	Description
0	Text sent and received using a string should be converted using the ANSI code page for the current locale.
1	Text sent and received using a string should be converted using the system default OEM code page. The OEM code page typically contains characters that are used by console applications and are based on character sets commonly used by MS-DOS. You should not use this code page unless you know the server is sending text which includes OEM characters.
1252	Text sent and received using a string should be converted using the Windows ANSI code page for western European languages. This code page is commonly used by legacy Windows applications for English and some other western languages. It should be noted that while this code page is similar to ISO 8859-1 character encoding, it is not identical.
28591	Text sent and received using a string should be converted using the ISO 8859-1 code page for western European languages. This code page is commonly referred to as Latin-1 and is similar to the Windows 1252 code page.
65000	Data that is sent and received using a string should be converted using UTF-7 encoding. If this code page is specified, data written to the socket will be encoded as UTF-7 encoded Unicode. All data received from the server will be converted from UTF-7. It is not recommended that you use this code page unless you know that the remote host is sending UTF-7 encoded text.
65001	Data that is sent and received using a string should be converted using UTF-8 encoding. If this code page is specified, data written to the socket will be encoded as UTF-8 encoded Unicode. All data received from the server will be converted from UTF-8 to UTF-16 Unicode. Because UTF-8 is backwards compatible with the ASCII character set, it is safe to use this encoding option when sending and receiving ASCII text.

A complete list of available [code page identifiers](#) can be found in Microsoft's documentation for the Win32 API.

All data which is exchanged over a socket is sent and received as 8-bit bytes, typically referred to as "octets" in networking terminology. However, the internal string type used by ActiveX controls are Unicode where each character is represented by 16 bits. To send and receive data using strings, these Unicode strings are converted to a stream of bytes.

By default, strings are converted to an array of bytes using the code page for the current locale, mapping the 16-bit Unicode characters to bytes. Similarly, when reading data from the socket into a

string buffer, the stream of bytes received from the remote host are converted to Unicode before they are returned to your application.

If you are exchanging text with another system and it appears to be corrupted or characters are being replaced with question marks or other symbols, it is likely the system is sending text which is using a different character encoding. Most services use UTF-8 encoding to represent non-ASCII characters and selecting the UTF-8 code page will typically resolve the issue.

Strings are only guaranteed to be safe when sending and receiving text. Using a string data type is not recommended when reading or writing binary data to a socket. If possible, you should always use a byte array as the buffer parameter for the **Read** and **Write** methods whenever you are exchanging binary data.

For backwards compatibility, the control defaults to using the code page for the current locale. This property value directly corresponds to Windows code page identifiers, and will accept any valid code page in addition to the values listed above. Setting this property to an invalid code page will result in an error.

Data Type

Integer (Int32)

See Also

[Read Method](#), [Write Method](#)

Command Property

Gets and sets the command to be executed on the server.

Syntax

object.Command [= *command*]

Remarks

The **Command** property sets the default command string that will be sent to the server when the **Execute** method is called and no command is explicitly specified as an argument.

Data Type

String

See Also

[Password Property](#), [RemotePort Property](#), [UserName Property](#), [Execute Method](#)

HostAddress Property

Gets and sets the IP address of the server.

Syntax

object.HostAddress [= *ipaddress*]

Remarks

The **HostAddress** property can be used to set the IP address for a server that you wish to communicate with. If the address is valid and matches an entry in the host table, the **HostName** property will be changed to match the address.

Data Type

String

See Also

[AutoResolve Property](#), [HostName Property](#)

HostName Property

Gets and sets the name of the server.

Syntax

object.HostName [= *hostname*]

Remarks

The **HostName** property should be set to the name of the server that you wish to communicate with. If the name is found in the host table, the **HostAddress** property is updated to reflect the IP address of the host.

Note that it is legal to assign an IP address to this property, but it is not legal to assign a host name to the **HostAddress** property.

Data Type

String

See Also

[AutoResolve Property](#), [HostAddress Property](#)

IsBlocked Property

Return if the control is blocked performing an operation.

Syntax

object.IsBlocked

Remarks

The **IsBlocked** property returns True if the specified control is blocked performing an operation. Because the Windows Sockets API only permits one blocking operation per thread of execution, this property should be checked before starting any blocking operation.

Note that this property will return True if there is *any* blocking operation being performed by the application, regardless if the specified control is responsible for the blocking operation or not.

Data Type

Boolean

See Also

[Blocking Property](#), [LastError Property](#)

IsConnected Property

Determine if the control is connected to a server.

Syntax

object.**IsConnected**

Remarks

The **IsConnected** read-only property is set to a value of true if the control is connected with a server, otherwise the property has a value of false.

Data Type

Boolean

IsInitialized Property

Determine if the control has been initialized.

Syntax

object.IsInitialized

Remarks

The **IsInitialized** property is used to determine if the current instance of the control has been initialized properly. Normally this is done automatically when the control is loaded, however there are circumstances where the control may not be able to initialize itself. If this property returns **False**, the application must call the **Initialize** method to initialize the control before performing any other operation.

The most common reason that the control may not initialize correctly is that no valid development or runtime license key can be found or the license key that was provided is invalid. It may also indicate a problem with the system configuration or user access rights, such as not being able to load the required networking libraries or not being able to access the system registry.

Data Type

Boolean

See Also

[Initialize Method](#)

IsReadable Property

Return if data can be read from the server without blocking.

Syntax

object.IsReadable

Remarks

The **IsReadable** property returns True if data can be read from the server without blocking. For non-blocking connections, this property can be checked before the application attempts to read the data, preventing an error.

Data Type

Boolean

See Also

[IsConnected Property](#), [Read Method](#), [OnRead Event](#)

IsWritable Property

Return if data can be sent to the server without blocking.

Syntax

object.IsWritable

Remarks

The **IsWritable** property returns True if data can be written without blocking. For non-blocking connections, this property can be checked before the application attempts to send data to the server, preventing an error.

If the **IsWritable** property returns False, this means that the application cannot write to the socket at that time. However, if the property returns True, this does not guarantee that you will be able to send data without an error. The next operation may result in an **stErrorOperationWouldBlock** or **stErrorOperationInProgress** error. The application must treat these errors as recoverable, and should be prepared to retry operations that result in them.

Data Type

Boolean

See Also

[IsReadable Property](#), [Write Method](#), [OnWrite Event](#)

LastError Property

Gets and sets the last error that occurred on the control.

Syntax

object.LastError [= *value*]

Remarks

The **LastError** property can be read to determine the last error that occurred for this control. If a value is assigned to this property, it must either be zero to clear the error or a valid error code for the control.

Data Type

Integer (Int32)

See Also

[LastErrorString Property](#), [OnError Event](#)

LastErrorString Property

Return a description of the last error to occur

Syntax

object.LastErrorString

Remarks

The **LastErrorString** property returns a description of the last error that occurred. This can be used to display a meaningful error message to a user, rather than just the numeric value returned by the **LastError** property.

Data Type

String

See Also

[LastError Property](#), [OnError Event](#)

Password Property

Gets and sets the password for the current user.

Syntax

object.Password [= *password*]

Remarks

The **Password** property specifies the password used to authenticate the user. This property is used as the default value for the **Connect** method if no password is specified as an argument.

Data Type

String

See Also

[UserName Property](#), [Execute Method](#), [Login Method](#)

RemotePort Property

Gets and sets the port number for a remote connection.

Syntax

object.RemotePort [= *portnumber*]

Remarks

The **RemotePort** property is used to set the port number that the control will use to establish a connection with the server.

The following values are the default port numbers used by the control:

Value	Description
rshPortExec	A connection is established with the server using port 512, the rexec service. This service requires that the client provide a username and password to execute the specified command.
rshPortLogin	A connection is established with the server using port 513, the rlogin service. This service is similar Telnet in that it provides an interactive login session. The client is provided with a command prompt and can enter commands which are executed on the server.
rshPortRshell	A connection is established with the server using port 514, the rshell service. This service uses host equivalence to authenticate the user. With host equivalence, the server considers the client to be equivalent to itself, and as long as the specified user exists on the server, the client is permitted to execute commands on behalf of the user without requiring a password. Host equivalence is configured by the server administrator.

Data Type

Integer (Int32)

See Also

[HostAddress Property](#), [HostName Property](#), [Execute Method](#), [Login Method](#)

Terminal Property

Gets and sets the terminal type used by the control.

Syntax

object.Terminal [= *termtype*]

Remarks

The **Terminal** property specifies the terminal type of the server for display purposes. On UNIX based systems, the terminal name corresponds to a termcap or terminfo entry as set in the TERM environment variable. On Windows based systems which implement the rlogin service, this property may be ignored and the server will assume that the client is capable of displaying ANSI escape sequences. On VMS systems, the terminal name should correspond to the terminal type used with the SET TERMINAL/DEVICE command.

If this property is set to an empty string and no terminal type is specified when the **Login** method is called, a default terminal type named "unknown" will be used. On most UNIX and VMS systems this defines a terminal which is not capable of cursor positioning using control or escape sequences. This terminal type may not be recognized and an error may be displayed when the user logs in indicating that the terminal type is invalid.

Refer to the documentation for the server system to determine what terminal type names are available to you. Remember that on UNIX systems, the terminal type is case-sensitive. Some of the more common terminal types are:

Terminal Type	Description
ansi	This terminal type is usually available on UNIX based servers. This specifies that the client is capable of displaying standard ANSI escape sequences for cursor control.
dumb	This terminal type typically specifies a terminal display which does not support control or escape sequences for cursor positioning. If you do not want escape sequences embedded in the data stream and the server returns an error if the terminal type is not specified, try using this terminal type.
pcansi	This terminal type is usually available on UNIX based servers. This specifies that the client is using a PC terminal emulator that supports basic ANSI escape sequences for cursor control. This may also enable escape sequences which can set the display colors.
vt100	This terminal type is usually available on UNIX and VMS based servers. On some VMS systems this string may need to be specified as DEC-VT100. This specifies that the client is capable of emulating a DEC VT100 terminal. The VT100 supports many of the same cursor control sequences as an ANSI terminal.
vt220	This terminal type is usually available on UNIX and VMS based servers. On some VMS systems this string may need to be specified as DEC-VT220. This specifies that the client is capable of emulating a DEC VT220 terminal, which is a later version of the VT100.
vt320	This terminal type is usually available on UNIX and VMS based servers. On

	some VMS systems this string may need to be specified as DEC-VT320. This specifies that the client is capable of emulating a DEC VT320 terminal, which is similar to the VT100 and VT220 and provides advanced features such as the ability to set display colors.
xterm	This terminal type is may be available on UNIX based servers which have X Windows installed. This specifies that the client is a using the X Windows xterm emulator which supports standard ANSI escape sequences for cursor control.

Data Type

String

See Also

[UserName Property](#), [Login Method](#)

ThrowError Property

Enables or disables error handling by the application.

Syntax

object.ThrowError = { True | False }

Remarks

Error handling for methods can be performed using either return codes or exceptions, depending on the value of this property.

If the **ThrowError** property is set to False, methods will return a status value indicating success or failure. Applications should check the return value of each method and use the **LastError** and **LastErrorString** properties to determine the cause of any error.

If the **ThrowError** property is set to True, errors occurring within the control will be raised to the host application as ActiveX exceptions. In addition, the **OnError** event will fire. This allows applications to use language-specific exception handling mechanisms, such as Visual Basic error handling, instead of checking individual return values after each method call.

Even when the **ThrowError** property is set to True, the **LastError** and **LastErrorString** properties will still be updated with information about the most recent error.

If an error occurs while accessing a property value, an exception will be raised regardless of the value of the **ThrowError** property. However, the **OnError** event will not be fired for property access errors.

Data Type

Boolean

Example

The following example handles errors by checking the return code of a method:

```
RshClient1.ThrowError = False
nError = RshClient1.Connect(strHostName)

If nError > 0 Then
    MsgBox RshClient1.LastErrorString, vbExclamation
    Exit Sub
End If
```

The following example handles errors by throwing them to the container:

```
On Error Resume Next: Err.Clear

RshClient1.ThrowError = True
RshClient1.Connect strHostName

If Err.Number <> 0
    MsgBox Err.Description, vbExclamation
    Exit Sub
End If
On Error GoTo 0
```

See Also

[LastError Property](#), [LastErrorString Property](#), [OnError Event](#)

Timeout Property

Gets and sets the amount of time until a blocking operation fails.

Syntax

object.Timeout [= *seconds*]

Remarks

Setting the **Timeout** property specifies the number of seconds until a blocking operation fails and the control returns an error.

Note that the **Timeout** property also determines the amount of time the control will spend attempting to connect to a server. If a connection is not established within the given time period, the connection attempt will fail.

Data Type

Integer (Int32)

Trace Property

Enable or disable network function level logging.

Syntax

`object.Trace` [= { True | False }]

Remarks

The **Trace** property is used to enable or disable the logging of network function calls. When enabled, each function call is logged to a file, including the function parameters, return value and error code if applicable. This facility can be enabled and disabled at run time, and the trace log file can be specified by setting the **TraceFile** property. All function calls that are being logged are appended to the trace file, if it exists. If no log file exists when tracing is enabled, the file is created.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

Data Type

Boolean

See Also

[TraceFile Property](#), [TraceFlags Property](#)

TraceFile Property

Gets and sets the name of the file to use when logging network function calls.

Syntax

`object.TraceFile [= filename ]`

Remarks

The **TraceFile** property is used to specify the name of the file that is created when logging is enabled. If this property is set to an empty string (the default value), then a file named **SocketTools.log** is created in the current user's Documents folder. It is recommended that you always specify a complete path to the log file. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

If the file exists, the output is appended to the file, otherwise the file is created. Since logging is enabled per-process, the log file is shared by all instances of the controls being used. If you create multiple instances of the control, you only need to enable logging for a single instance. Because log files can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "0x". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxx:xxxx:xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, the control is attempting to connect to a system with the IPv4 address 192.0.0.1 on port 1234.

If the log file cannot be created, or the user does not have permission to modify an existing file, the error is silently ignored and no output will be generated.

Data Type

String

See Also

TraceFlags Property

Gets and sets the network function logging flags.

Syntax

object.TraceFlags [= *flags*]

Remarks

The **TraceFlags** property is used to specify the type of information written to the trace file when socket function tracing is enabled. The following values may be used:

Value	Description
dnsTraceInfo	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
dnsTraceError	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
dnsTraceWarning	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
dnsTraceHexDump	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
dnsTraceTruncate	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.

Since logging is enabled per-process, the trace flags are shared by all instances of the control being used. If multiple controls have tracing enabled, the **TraceFlags** property should be set to the same value for each control. Changing the trace flags for any one instance of the control will affect the logging performed for all other instances used by the application.

Warnings are generated when a non-fatal error is returned by a Windows Sockets function. For example, if data is being written through the control and an error indicating that the operation would block is returned, only a warning is logged since the application simply needs to attempt to write the data at a later time.

Data Type

Integer (Int32)

See Also

[Trace Property](#), [TraceFile Property](#)

UserName Property

Gets and sets the current user name.

Syntax

object.UserName [= *username*]

Remarks

The **UserName** property specifies the user that is logging in to the server, and is required for authentication purposes. This property is used as the default value for the **Connect** method if no password is specified as an argument.

Data Type

String

See Also

[Password Property](#), [Execute Method](#), [Login Method](#)

Version Property

Return the current version of the control.

Syntax

object.Version

Remarks

The **Version** property returns the current version of the object. This can be used by an application for validation purposes. The version returned is composed of four numbers, separated by periods. The first number is the major version number, the second number is the minor version number, the third is the build number and the fourth is the revision number.

Data Type

String

Remote Command Control Methods

Method	Description
Cancel	Cancels the current blocking network operation
Disconnect	Terminate the connection with a server
Execute	Execute the specified command on the server
Initialize	Initialize the control and validate the runtime license key
Login	Establish an interactive terminal session for the specified user
Read	Return data read from the server
Reset	Reset the internal state of the control
Search	Search for a specific character sequence in the data stream
SendKey	Send a key code to the server
Uninitialize	Uninitialize the control and release any system resources that were allocated
Write	Write data to the server

Cancel Method

Cancels the current blocking network operation.

Syntax

object.Cancel

Parameters

None.

Return Value

None.

Remarks

The **Cancel** method cancels any blocking network operation in the current thread. This is typically used inside an event handler, causing the blocking method to return to the caller with an error indicating that the current operation was canceled. This method sets an internal flag that is periodically checked during a blocking operation, such as waiting for more data to arrive. If the current thread is not blocked at the time that this method is called, it will have no effect.

See Also

[Disconnect Method](#), [Reset Method](#), [OnCancel Event](#)

Disconnect Method

Terminate the connection with a server.

Syntax

object.Disconnect

Parameters

None.

Return Value

A value of zero is returned if the connection was terminated successfully. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

This method terminates the network connection with the server.

See Also

[IsConnected Property](#), [Execute Method](#), [Login Method](#), [OnDisconnect Event](#)

Execute Method

Execute the specified command on the server.

Syntax

```
object.Execute( [RemoteHost], [RemotePort], [UserName], [Password], [Command], [Timeout],  
[Options] )
```

Parameters

RemoteHost

A optional string argument which specifies the name of the server to connect to. The string may either be an IP address or a fully qualified domain name. If the argument is omitted, the value of the **HostAddress** or **HostName** property will be used.

RemotePort

An optional integer argument which specifies the port number to connect to. This method may be used to either connect to the rexec service or the rshell service, and which service is selected depends on the port number provided. If this argument is omitted, the value of the **RemotePort** property will be used.

Value	Description
rshPortExec	A connection is established with the server using port 512, the rexec service. This service requires that the client provide a username and password to execute the specified command.
rshPortRshell	A connection is established with the server using port 514, the rshell service. This service uses host equivalence to authenticate the user. With host equivalence, the server considers the client to be equivalent to itself, and as long as the specified user exists on the server, the client is permitted to execute commands on behalf of the user without requiring a password. Host equivalence is configured by the server administrator.

UserName

An optional string argument which specifies the username which used to authenticate the client session. If this argument is omitted, the value of the **UserName** property will be used.

Password

An optional string argument which specifies the password to be used to authenticate the user. If this argument is omitted, the value of the **Password** property will be used. A password is only used if the client is connecting to the rexec service. The rshell service uses host equivalence to authenticate the user and this argument will be ignored.

Command

An optional string argument which specifies the command to be executed on the server. If this argument is omitted, the value of the **Command** property will be used.

Timeout

An optional integer argument which specifies the number of seconds that the client will wait for a response from the server. If this argument is omitted, the value of the **Timeout** property will be used. This value is only used for synchronous connections where the **Blocking** property is set to True.

Options

An optional integer argument which specifies one or more connection options. This argument is reserved for future use and should be omitted.

Return Value

A value of zero is returned if the operation was successful, otherwise a non-zero error code is returned which indicates the cause of the failure.

Remarks

This method executes the specified command on a server. Output from the command may be read using the **Read** method. Input can be supplied to the program using the **Write** method. To search for a specific sequence of bytes in the output returned by the server, use the **Search** method.

See Also

[Disconnect Method](#), [Login Method](#), [Read Method](#), [Search Method](#)

Initialize Method

Initialize the control and validate the runtime license key.

The Remote Shell (rsh/rcmd) protocol is deprecated, insecure, and should never be used. This protocol transmits user credentials and command data in plaintext, making it vulnerable to interception, spoofing, and other network-based attacks. Support for this protocol will be removed in a future release. For secure remote command execution and interactive terminal sessions, it is recommended you use the [Secure Shell](#) ActiveX control.

Syntax

object.Initialize([*LicenseKey*])

Parameters

LicenseKey

An optional string value which specifies a runtime license key used to initialize the control. If the license key is omitted or passed as an empty string, a development license must be installed on the local system.

Return Value

A value of zero is returned if the control was initialized successfully. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

This method dynamically loads other system libraries and allocates thread local storage. In most cases, it is not necessary to call this method directly because it is automatically invoked when an instance of the control is created by the container. However, if the control is created dynamically using **CreateObject** or a similar method, this must be the first method that is called before you attempt to modify any property values or invoke other methods. Failure to initialize the control may result in subsequent errors and/or cause an exception to be raised.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the control will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the control was created.

If the control is being used within another DLL, it is important that you do not attempt to create an instance of the control or call the **Initialize** method from within the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is written in C++ and it is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for any static and global C++ objects and has the same restrictions.

Example

```
Set rshClient = CreateObject("SocketTools.RshClient.12")

nError = rshClient.Initialize(strLicenseKey)
If nError > 0 Then
    MsgBox "Unable to initialize SocketTools component"
End
End If
```

See Also

[IsInitialized Property](#), [Uninitialize Method](#)

Login Method

Establish an interactive terminal session for the specified user.

Syntax

object.Login([*RemoteHost*], [*RemotePort*], [*UserName*], [*Timeout*], [*Options*])

Parameters

RemoteHost

A optional string argument which specifies the name of the server to connect to. The string may either be an IP address or a fully qualified domain name. If the argument is omitted, the value of the **HostAddress** or **HostName** property will be used.

RemotePort

An optional integer argument which specifies the port number to connect to. If this argument is omitted, the value of the **RemotePort** property will be used. A remote port of zero specifies that port 513 should be used, which is the standard port number for the rlogin service.

UserName

An optional string argument which specifies the username which should be used to authenticate the client session. If this argument is omitted, the value of the **UserName** property will be used.

Timeout

An optional integer argument which specifies the number of seconds that the client will wait for a response from the server. If this argument is omitted, the value of the **Timeout** property will be used. This value is only used for synchronous connections where the **Blocking** property is set to True.

Options

An optional integer argument which specifies one or more connection options. This argument is reserved for future use and should be omitted.

Return Value

A value of zero is returned if the operation was successful, otherwise a non-zero error code is returned which indicates the cause of the failure.

Remarks

This method logs the specified user in on the server. Note that no password is provided to the server. This is because the remote login service uses *user equivalence*. If the client system is recognized by the server as being equivalent, the login will proceed directly. If the client system is not recognized, the server will prompt the user for a password. For more information about user equivalence and the remote login service, refer to your server's operating system documentation.

Output from the command may be read using the **Read** method. Input can be supplied to the program using the **Write** method. To search for a specific sequence of bytes in the output returned by the server, use the **Search** method.

See Also

[Disconnect Method](#), [Execute Method](#), [Read Method](#), [Search Method](#)

Read Method

Return data read from the server.

Syntax

object.Read(*Buffer*, [*Length*])

Parameters

Buffer

A buffer that the data will be stored in. If the variable is a String then the data will be returned as a string of characters. This is the most appropriate data type to use if the server is sending data that consists of printable characters. If the server is sending binary data, it is recommended that a Byte array be used instead.

Length

A numeric value which specifies the number of bytes to read. Its maximum value is $2^{31}-1 = 2147483647$. This argument is required to be present for string data. If a value is specified for this argument for other permissible types of data, and it is less than number of bytes that is determined by the control, then ***Length*** will override the internally computed value. If the argument is omitted, then the maximum number of bytes to read is determined by the size of the buffer.

Return Value

The number of bytes actually read from the server is returned by this method. If an error occurs, a value of -1 is returned.

Remarks

The **Read** method returns data that has been read from the server, up to the number of bytes specified. If no data is available to be read, an error will be generated if the control is non-blocking mode. If the control is in blocking mode, the program will stop until data is returned by the server or the connection is closed. Note that it is possible for the returned data to contain embedded null characters.

See Also

[IsConnected Property](#), [IsReadable Property](#), [Write Method](#), [OnRead Event](#), [OnWrite Event](#)

Reset Method

Reset the internal state of the control.

Syntax

object.Reset

Parameters

None.

Return Value

None.

Remarks

The **Reset** method resets the internal state of the control. Property values are initialized to their internal defaults, open network connections will be closed and any handles allocated by the control will be released.

See Also

[Cancel Method](#), [Initialize Method](#), [Uninitialize Method](#)

Search Method

Search for a specific character sequence in the data stream.

Syntax

object.Search(*String*, [*Buffer*], [*Length*], [*Options*])

Parameters

String

A string argument which specifies the sequence of characters to search for in the data stream. When the control encounters this sequence, the method will return.

Buffer

An optional string or byte array buffer that will contain the output sent by the server, up to and including the search string character sequence. If this argument is omitted, the control will still search for the character sequence but any output sent by the server will be discarded.

Length

An optional integer value which specifies the maximum number of bytes of data to store in the buffer. If this argument is omitted, no limit will be placed on the amount of output buffered by the control.

Options

An optional integer argument which is reserved for future use. This argument should be omitted.

Return Value

This method returns a boolean value. A return value of true indicates that the search string was found in the data stream. A return value of False indicates that the search string was not found in the amount of time specified by the **Timeout** property or that the server closed the connection.

Remarks

The **Search** method searches for a character sequence in the data stream and stops reading when it is found. This is useful when the client wants to automate responses to the server, such as executing a command and processing the output. The function collects the output from the server and stores it in a buffer provided by the caller. When the function returns, the buffer will contain everything sent by the server up to and including the search string.

See Also

[IsReadable Property](#), [Timeout Property](#), [Execute Method](#), [Login Method](#), [Read Method](#)

SendKey Method

Send a key code to the server.

Syntax

object.SendKey(*Key*)

Parameters

Key

A value which specifies the key code to send to the server. This may be a single byte, in which case it is sent to the server as-is. If a numeric value is specified, then this is considered to be an ASCII character value and it is sent to the server as a single byte. The value must be between 1 and 255. If the key code value is 0, then the method returns without sending any data. If the value is greater than 255, an error will be raised. If the **Key** argument is a string, then the method will send that string to the server. An empty string is ignored and the method will return without sending any data. An error will be returned if the string is longer than 128 bytes.

Return Value

This method will return a value of true if the key code was successfully sent to the server. If the key cannot be sent, the method will return False and the **LastError** property will contain the error code that indicates the reason for the failure. This method will also return False if the key code value is zero or an empty string is passed by the caller.

Remarks

The **SendKey** method sends a key code to the server. This method is useful if the application needs to send a single character to the server, as opposed to using the **Write** method which should be used for sending large amounts of data.

The strings sent by the **SendKey** method are typically short escape sequences which are generated by a terminal emulator when the user presses a special key, such as a function key. For example, a DEC VT100 terminal sends the escape sequence <ESC>[M when the user presses the F1 function key. To simulate this, those three bytes could be passed as the **Key** value.

Example

The following example demonstrates how to use the **SendKey** method in conjunction with the **KeyMapped** and **KeyPress** events in the Terminal Emulator control:

```
Private Sub Terminal1_KeyMapped(KeyIndex As Integer, Shift As Integer, KeyString As String)
    RshClient1.SendKey KeyString
End Sub

Private Sub Terminal1_KeyPress(KeyAscii As Integer)
    RshClient1.SendKey KeyAscii
End Sub
```

See Also

[IsWritable Property](#), [Write Method](#), [OnWrite Event](#)

Uninitialize Method

Uninitialize the control and release any system resources that were allocated.

Syntax

object.Uninitialize

Parameters

None.

Return Value

None.

Remarks

The **Uninitialize** method terminates any connection established by the control and resets the internal state of the control. This method is not typically used because any resources that have been allocated by an instance of the control will automatically be released when it is destroyed.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the control will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the control was created. An application should only call the **Uninitialize** method if it has explicitly called the **Initialize** method.

See Also

[Initialize Method](#)

Write Method

Write data to the server.

Syntax

object.Write(*Buffer*, [*Length*])

Parameters

Buffer

A buffer variable that contains the data to be written to the server. If the variable is a **String** type, then the data will be written as a string of characters. This is the most appropriate data type to use if the server expects text data that consists of printable characters. If the server is expecting binary data, it is recommended that a **Byte** array be used instead.

Length

A numeric value which specifies the number of bytes to write. Its maximum value is $2^{31}-1 = 2147483647$. If a value is specified for this argument and it is greater than the actual size of the buffer, then the **Length** argument will be ignored and the entire contents of the buffer will be written. If the argument is omitted, then the maximum number of bytes to write is determined by the size of the buffer.

Return Value

This method returns the number of bytes actually written to the server, or -1 if an error was encountered.

Remarks

The **Write** method sends the data in *buffer* to the server. If the connection is buffered, as is typically the case, the data is copied to the send buffer and control immediately returns to the program. If the control is blocking, the application will wait until the data can be sent. If the control is non-blocking and the write fails because it could not send all of the data to the server, the **OnWrite** event will be fired when the server can accept data again.

See Also

[IsConnected Property](#), [IsWritable Property](#), [Timeout Property](#), [Read Method](#), [SendKey Method](#), [OnWrite Event](#)

Remote Command Control Events

Event	Description
OnCancel	This event occurs when a blocking operation is canceled
OnConnect	This event occurs when a connection is established
OnDisconnect	This event occurs when a connection is terminated
OnError	This event occurs when a control error occurs
OnRead	This event occurs when data is available to be read
OnTimeout	This event occurs when a blocking operation times out
OnWrite	This event occurs when data can be written to the server

OnCancel Event

The **OnCancel** event is generated when a blocking operation is canceled.

Syntax

Sub *object_OnCancel* ([*Index As Integer*])

Remarks

This event occurs when a blocking operation on the socket, such as sending or receiving data, is canceled with the **Cancel** method. To assist in determining which operation was canceled, consult the **State** property.

See Also

[Cancel Method](#), [OnError Event](#), [OnTimeout Event](#)

OnConnect Event

The **OnConnect** event is generated when a connection is established.

Syntax

Sub *object_OnConnect* ([*Index As Integer*])

Remarks

The **OnConnect** event is generated when a connection is made with a server as a result of a **Connect** method call. This event is only triggered when the **Blocking** property is set to False.

See Also

[Blocking Property](#), [Execute Method](#), [Login Method](#), [OnDisconnect Event](#), [OnWrite Event](#)

OnDisconnect Event

The **OnDisconnect** event is generated when a connection is terminated.

Syntax

Sub *object_OnDisconnect* ([*Index As Integer*])

Remarks

The **OnDisconnect** event is generated when the connection is terminated by the server. This event is only triggered when the **Blocking** property is set to False.

When the **OnDisconnect** event fires, it is possible that there may still be buffered data available to read from the server. Before disconnecting from the server, the application should attempt to read any remaining data until the **Read** method returns a value of zero, or returns an error indicating that the operation would block.

See Also

[Blocking Property](#), [IsConnected Property](#), [IsReadable Property](#), [Disconnect Method](#), [Read Method](#), [OnConnect Event](#)

OnError Event

The **OnError** event is generated when a control error occurs.

Syntax

Sub *object_OnError* ([*Index As Integer*,] **ByVal** *ErrorCode As Variant*, **ByVal** *Description As Variant*)

Remarks

This event occurs when an error occurs during a control action. Errors not generated by the control itself, such as errors related to the programming language or general component errors, do not trigger this event.

The ***ErrorCode*** argument specifies the last error that has occurred. If the error is network related, the error code values returned by the control correspond to those returned by the standard Windows Sockets library.

The ***Description*** argument is a string that describes the error.

See Also

[LastError Property](#), [LastErrorString Property](#), [ThrowError Property](#)

OnRead Event

The **OnRead** event is generated when data is available to be read.

Syntax

Sub *object_OnRead* ([*Index As Integer*])

Remarks

The **OnRead** event is generated for non-blocking sockets when data is available to be read from the server. Use the **Read** method to read the data. This event is only triggered when the **Blocking** property is set to False.

See Also

[IsReadable Property](#), [Read Method](#), [Write Method](#), [OnWrite Event](#)

OnTimeout Event

The **OnTimeout** event is fired when a blocking operation times out.

Syntax

Sub *object_OnTimeout* ([*Index As Integer*])

Remarks

The **OnTimeout** event is generated when a blocking socket operation, such as sending or receiving data, times out. To determine which operation was in progress when the timeout occurred, consult the **State** property. This event is only triggered when the **Blocking** property is set to True.

See Also

[Timeout Property](#), [OnCancel Event](#)

OnWrite Event

The **OnWrite** event is generated when data can be written to the server.

Syntax

Sub *object_OnWrite* ([*Index As Integer*])

Remarks

The **OnWrite** event is generated for non-blocking sockets when data can be written to the server after a previous attempt failed because it would cause the control to block. This event is only triggered when the **Blocking** property is set to False.

[IsWritable Property](#), [Read Method](#), [SendKey Method](#), [Write Method](#), [OnConnect Event](#), [OnRead Event](#)

Simple Mail Transfer Protocol Control

Submit email messages for delivery to one or more recipients.

Reference

- [Properties](#)
- [Methods](#)
- [Events](#)
- [Error Codes](#)

Control Information

Object Name	SmtpClientCtl.SmtpClient
File Name	CSMTPX12.OCX
Version	12.0.3024.1286
ProgID	SocketTools.SmtpClient.12
ClassID	BBA70E4B-7D7B-47B8-8D48-1FDE35F67FD5
Threading Model	Apartment
Help File	CST12CTL.CHM
Dependencies	None
Standards	RFC 821, RFC 1425, RFC 1869, RFC 2821

Overview

The Simple Mail Transfer Protocol (SMTP) enables applications to deliver email messages to one or more recipients. The control provides an interface for addressing and delivering messages, and extended features such as user authentication and delivery status notification. Unlike Microsoft's Messaging API (MAPI) or Collaboration Data Objects (CDO), there is no requirement to have certain third-party email applications installed or specific types of servers installed on the local system. The control can be used to deliver mail through a wide variety of systems, from standard UNIX based mail servers to Windows systems running Exchange or Lotus Notes and Domino.

Using this control, messages can be delivered directly to the recipient, or they can be submitted to a relay server, such as a company or service provider's mail system. The [MailMessage](#) control can be integrated with this control in order to provide a flexible interface for composing and delivering messages.

The control supports secure explicit and implicit connections using TLS 1.2 or later with client certificates for authentication. By simply setting a few properties, a secure connection using 256-bit AES encryption can be established, providing your application with the highest level of security available. Authentication is supported using both standard passwords and OAuth bearer tokens.

Requirements

The SocketTools ActiveX Edition components are self-registering controls that are compatible with any programming language that supports the Component Object Model (COM) and the ActiveX control specification. If you are using Visual Basic 6.0, Service Pack 6 (SP6) is required. We recommend installing all available updates for your development tools. Although the Visual Basic 6.0 runtime is

supported on Windows 11, the IDE itself is no longer officially supported by Microsoft. Legacy IDEs and compilers may also require elevated (administrator) privileges to run properly.

The ActiveX controls are supported on Windows 7, Windows Server 2008 R2, and later versions of both desktop and server editions of Windows. For Windows 7, Service Pack 1 (SP1) is the minimum requirement. For Windows 8 systems, the 8.1 update must be installed. On ARM-based platforms, the minimum supported version is Windows 10 build 1709.

SocketTools includes components for both 32-bit (x86) and 64-bit (x64) Windows platforms. All modern versions of Windows are 64-bit, but we continue to include 32-bit components for compatibility with legacy development tools such as Visual Basic 6.0. We also provide native ARM64 ActiveX controls for systems running Windows on ARM. Note that 32-bit applications on ARM run using x86 emulation, and Microsoft no longer supports native ARM32 applications.

If you are using VBScript, Visual Basic for Applications (VBA), or another scripting environment on an ARM-based system, be aware that 64-bit hosts will require ARM64 components, while 32-bit hosts will use x86 components under emulation. This includes applications created with Visual Basic 6.0. To reduce deployment complexity and avoid confusion, SocketTools does not include ARM32 ActiveX controls in its standard redistribution packages but they are available on request for legacy or specialized scenarios.

Distribution

When you distribute an application that uses this control, you can either install the file in the same folder as your application executable or as a shared component in the appropriate system folder. If you install the control in the system folder, it is important that you distribute the correct version for the target platform and it must be registered. If you install the control in the same folder as your executable, it is recommended that you use registration-free activation or COM redirection to ensure that the correct version of the control is loaded by the application.

Simple Mail Transfer Protocol Control Properties

Property	Description
AuthType	Gets and sets the method used to authenticate the user
AutoResolve	Determines if host names and IP addresses are automatically resolved
BearerToken	Gets and sets the OAuth 2.0 bearer token used for authentication
Blocking	Gets and sets the blocking state of the control
CertificateExpires	Return the date and time that the server certificate expires
CertificateIssued	Return the date and time that the server certificate was issued
CertificateIssuer	Returns information about the organization that issued the server certificate
CertificateName	Gets and sets the common name for the client certificate
CertificatePassword	Gets and sets the password associated with the client certificate
CertificateStatus	Return the status of the server certificate
CertificateStore	Gets and sets the name of the client certificate store or file
CertificateSubject	Returns information about the organization to which the server certificate was issued
CertificateUser	Gets and sets the user that owns the client certificate
CipherStrength	Return the length of the key used by the encryption algorithm
CurrentDate	Return the current date in the standard format used by email messages
Extended	Enable support for extended SMTP commands
HashStrength	Return the length of the message digest that was selected
HostAddress	Gets and sets the IP address of the server
HostName	Gets and sets the name of the server
IsBlocked	Return if the control is blocked performing an operation
IsConnected	Determine if the control is connected to a server
IsInitialized	Determine if the control has been initialized
IsWritable	Return if data can be sent to the server without blocking
LastError	Gets and sets the last error that occurred on the control
LastErrorString	Return a description of the last error to occur
LocalDomain	Gets and sets the local domain name
Options	Gets and sets the options that are used in establishing a connection
Password	Gets and sets the password for the current user
RemotePort	Gets and sets the port number for a remote connection
ResultCode	Return the result code of the previous action
ResultString	Return a string describing the results of the previous action
ReturnReceipt	Enable or disable delivery status notification
Secure	Set or return if a connection to the server is secure

SecureCipher	Return the encryption algorithm used to establish the secure connection with the server
SecureHash	Return the message digest selected when establishing the secure connection with the server
SecureKeyExchange	Return the key exchange algorithm used to establish the secure connection with the server
SecureProtocol	Gets and sets the security protocol used to establish the secure connection with the server
ThrowError	Enables or disables error handling by the application
Timeout	Gets and sets the amount of time until a blocking operation fails
Trace	Enable or disable socket function level tracing
TraceFile	Specify the socket function trace output file
TraceFlags	Gets and sets the socket function tracing flags
UserName	Gets and sets the current user name
Version	Return the current version of the control

AuthType Property

Gets and sets the method used to authenticate the user.

Syntax

object.AuthType [= *type*]

Remarks

The **AuthType** property specifies the type of authentication that should be used when the client connects to the mail server. The following authentication methods are supported:

Value	Description
smtpAuthLogin	The client will authenticate using the AUTH LOGIN command. This encodes the username and password, however the credentials are not encrypted and it is recommended you use a secure connection. This is the default method accepted by most mail servers and is the preferred authentication type for most clients.
smtpAuthPlain	The client will authenticate using the AUTH PLAIN command. This encodes the username and password, however the credentials are not encrypted and it is recommended you use a secure connection. The server must support the PLAIN Simple Authentication and Security Layer (SASL) mechanism as defined in RFC 4616.
smtpAuthXOAuth2	The client will authenticate using the AUTH XOAUTH2 command. This authentication method does not require the user password, instead the BearerToken property must specify the OAuth 2.0 bearer token issued by the service provider. The application must provide a valid access token which has not expired or the user authentication will fail.
smtpAuthBearer	The client will authenticate using the AUTH OAUTHBEARER command as defined in RFC 7628. This authentication method does not require the user password, instead the BearerToken property must specify the OAuth 2.0 bearer token issued by the service provider. The application must provide a valid access token which has not expired or the user authentication will fail.

Data Type

Integer (Int32)

Remarks

The default authentication method is **smtpAuthLogin** and this is accepted by most mail servers. If you attempt to use an authentication method which is not supported by the server, the **Authenticate** method will fail and the last error code will be set to **stErrorInvalidAuthenticationType**.

All authentication methods require the mail server to support the standard service extensions for authentication as specified in the RFC 4954. The server must support the ESMTP protocol extensions and the AUTH command. A user name and password are required for authentication. If you wish to authenticate without a user password, you must use one of the OAuth 2.0 authentication methods.

You should only use an OAuth 2.0 authentication method if you understand the process of how to request the access token. Obtaining an access token requires registering your application with the mail

service provider (e.g.: Microsoft or Google), getting a unique client ID associated with your application and then requesting the access token using the appropriate scope for the service. Obtaining the initial token will typically involve interactive confirmation on the part of the user, requiring they grant permission to your application to access their mail account.

The **smtpAuthXOAuth2** and **smtpAuthBearer** authentication methods are similar, but they are not interchangeable. Both use an OAuth 2.0 bearer token to authenticate the client session, but they differ in how the token is presented to the server. It is currently preferable to use the XOAUTH2 method because it is more widely available and some service providers do not yet support the OAUTHBEARER method.

Changing the value of the **BearerToken** property will automatically set the current authentication method to use OAuth 2.0.

See Also

[BearerToken Property](#), [Password Property](#), [UserName Property](#), [Authenticate Method](#), [Connect Method](#)

AutoResolve Property

Determines if host names and IP addresses are automatically resolved.

Syntax

object.AutoResolve [= { True | False }]

Remarks

Setting the **AutoResolve** property determines if the control automatically resolves host names and addresses specified by the **HostName** and **HostAddress** properties. If set to True, setting the **HostName** property will cause the control to automatically determine the corresponding IP address and set the **HostAddress** property accordingly. Likewise, setting the **HostAddress** property will cause the control to determine the host name and set the **HostName** property. Setting the property to False prevents the control from resolving host names until a connection attempt is made.

Note that setting the **HostName** or **HostAddress** property may cause the current thread to block, sometimes for several seconds, until the name or address is resolved. To prevent this behavior, set **AutoResolve** to False.

Data Type

Boolean

See Also

[HostAddress Property](#), [HostName Property](#)

BearerToken Property

Gets and sets the OAuth 2.0 bearer token for the current user.

Syntax

object.BearerToken [= *token*]

Remarks

The **BearerToken** property specifies the OAuth 2.0 bearer token used to authenticate the user. This property is used as the default value for the **Authenticate** method if the token is not provided as an parameter.

Assigning a value to this property will change the current authentication method to use OAuth 2.0 if necessary.

You should only use an OAuth 2.0 authentication method if you understand the process of how to request the access token. Obtaining an bearer token requires registering your application with the mail service provider (e.g.: Microsoft or Google), getting a unique client ID associated with your application and then requesting the token using the appropriate scope for the service. Obtaining the initial token will typically involve interactive confirmation on the part of the user, requiring they grant permission to your application to access their mail account.

Your application should not store an OAuth 2.0 bearer token for later use. They have a relatively short lifespan, typically about an hour, and are designed to be used with that session. You should specify offline access as part of the OAuth 2.0 scope if necessary and store the refresh token provided by the service. The refresh token has a much longer validity period and can be used to obtain a new bearer token when needed.

If the current authentication method does not use OAuth 2.0, this property will return an empty string and you should check the value of the **Password** property to obtain the current user's password. Refer to the **AuthType** property for more information on the available authentication methods.

Data Type

String

See Also

[AuthType Property](#), [Password Property](#), [UserName Property](#), [Authenticate Method](#), [Connect Method](#)

Blocking Property

Gets and sets the blocking state of the control.

Syntax

object.**Blocking** [= { True | False }]

Remarks

Setting the **Blocking** property determines if control actions complete synchronously or asynchronously. If set to True, then each control action, such as sending or receiving data, will return when the operation has completed or timed-out. If set to False, control actions will return immediately. If the operation would result in the control blocking, such as attempting to read data when none has been written, an error is generated. Events such as **OnConnect**, **OnDisconnect** and **OnWrite** are only fired if the connection is non-blocking.

Data Type

Boolean

See Also

[IsBlocked Property](#), [IsWritable Property](#)

CertificateExpires Property

Return the date and time that the server certificate expires.

Syntax

object.CertificateExpires

Remarks

The **CertificateExpires** property returns the date and time that the server certificate expires. This property will return an empty string if a secure connection has not been established with the server.

Data Type

String

See Also

[CertificateIssued Property](#), [CertificateIssuer Property](#), [CertificateStatus Property](#), [CertificateSubject Property](#), [Secure Property](#)

CertificateIssued Property

Return the date and time that the server certificate was issued.

Syntax

object.CertificateIssued

Remarks

The **CertificateIssued** property returns the date and time that the server certificate was issued. This property will return an empty string if a secure connection has not been established with the server.

Data Type

String

See Also

[CertificateExpires Property](#), [CertificateIssuer Property](#), [CertificateStatus Property](#), [CertificateSubject Property](#), [Secure Property](#)

CertificateIssuer Property

Returns information about the organization that issued the server certificate.

Syntax

object.CertificateIssuer

Remarks

The **CertificateIssuer** property returns a string that contains information about the organization that issued the server certificate. The string value is a comma separated list of tagged name and value pairs. In the nomenclature of the X.500 standard, each of these pairs are called a relative distinguished name (RDN), and when concatenated together, forms the issuer's distinguished name (DN). For example:

C=US, O="RSA Data Security, Inc.", OU=Secure Server Certification Authority

To obtain a specific value, such as the name of the issuer or the issuer's country, the application must parse the string returned by this property. Some of the common tokens used in the distinguished name are:

Name	Description
C	The ISO standard two character country code
S	The name of the state or province
L	The name of the city or locality
O	The name of the company or organization
OU	The name of the department or organizational unit
CN	The common name; with X.509 certificates, this is the domain name of the site the certificate was issued for

This property will return an empty string if a secure connection has not been established with the server.

Data Type

String

Example

The following example demonstrates how to extract the value of a relative distinguished name token:

```
Function GetCertNameValue(ByVal strValue As String, ByVal strFieldName As String)
As String
    Dim strFieldValue As String
    Dim cchValue As Integer, cchFieldName As Integer
    Dim nOffset As Integer

    GetCertNameValue = ""
    cchValue = Len(strValue)
    cchFieldName = Len(strFieldName)

    If cchValue = 0 Or cchFieldName = 0 Then
        Exit Function
    End If
```

```

nOffset = InStr(strValue, strFieldName & "=")

If nOffset > 0 Then
    '
    ' If the field name was found in the string, then
    ' remove everything to the left of the token from
    ' the string
    '
    strFieldValue = Right(strValue, cchValue - (nOffset + cchFieldName))

    '
    ' If the value is quoted, then strip off the leading
    ' quote and look for the ending quote in the string;
    ' otherwise look for the comma that marks the end of
    ' the field name/value pair
    '
    If Left(strFieldValue, 1) = Chr(34) Then
        strFieldValue = Right(strFieldValue, Len(strFieldValue) - 1)
        nOffset = InStr(strFieldValue, Chr(34))
    Else
        nOffset = InStr(strFieldValue, ",")
    End If

    '
    ' If the offset is 0, then the name/value pair is
    ' the last token in the string; otherwise, remove
    ' everything to the right of that position
    '
    If nOffset > 0 Then
        strFieldValue = Left(strFieldValue, nOffset - 1)
    End If

    GetCertNameValue = strFieldValue
End If

```

End Function

This function could then be used to return the name of the company who issued the server certificate:

```

Dim strIssuer As String
Dim strCompanyName As String

strIssuer = SmtplibClient1.CertificateIssuer
If Len(strIssuer) = 0 Then
    MsgBox "A secure connection has not been established"
Else
    strCompanyName = GetCertNameValue(strIssuer, "O")
    MsgBox "This certificate was issued by " & strCompanyName
End If

```

See Also

[CertificateExpires Property](#), [CertificateIssued Property](#), [CertificateStatus Property](#), [CertificateSubject Property](#), [Secure Property](#)

CertificateName Property

Gets and sets the common name for the client certificate.

Syntax

object.CertificateName [= *name*]

Remarks

This property sets the common name or friendly name of the certificate that should be used to establish the connection with the server. It is only required that you set this property value if the server requires a client certificate for authentication. If this property is not set, a client certificate will not be provided to the server. If a certificate name is specified, the certificate must have a private key associated with it, otherwise the connection attempt will fail because the control will be unable to create a security context for the session.

Certificates may be installed and viewed on the local system using the Certificate Manager that is included with the Windows operating system. For more information, refer to the documentation for the Microsoft Management Console.

Data Type

String

See Also

[CertificateStore Property](#), [Secure Property](#)

CertificatePassword Property

Gets and sets the password associated with the client certificate.

Syntax

object.CertificatePassword [= *password*]

Remarks

This property sets the password that should be used to access a certificate in the specified certificate store. It is only required when the **CertificateStore** property specifies a file that contains a certificate and private key in PKCS #12 format.

Data Type

String

See Also

[CertificateName Property](#), [CertificateStore Property](#), [Secure Property](#)

CertificateStatus Property

Return the status of the server certificate.

Syntax

object.CertificateStatus

Remarks

The **CertificateStatus** property returns an integer value which identifies the status of the server certificate. This property may return one of the following values:

Value	Description
stCertificateNone	No certificate information is available. A secure connection was not established with the server.
stCertificateValid	The certificate is valid.
stCertificateNoMatch	The certificate is valid, however the domain name specified in the certificate does not match the domain name of the site that the client has connected to. This is typically the case if the HostAddress property is used rather than the HostName property. It is recommended that the client examine the CertificateSubject property to determine the domain name of the site that the certificate was issued for.
stCertificateExpired	The certificate has expired and is no longer valid. The client can examine the CertificateExpires property to determine when the certificate expired.
stCertificateRevoked	The certificate has been revoked and is no longer valid. It is recommended that the client application immediately terminate the connection if this status is returned.
stCertificateUntrusted	The certificate has not been issued by a trusted authority, or the certificate is not trusted on the local host. It is recommended that the client application immediately terminate the connection if this status is returned.
stCertificateInvalid	The certificate is invalid. This typically indicates that the internal structure of the certificate is damaged. It is recommended that the client application immediately terminate the connection if this status is returned.

This property value should be checked after the connection to the server has completed, but prior to beginning a transaction. If a secure connection has not been established, this property will return a value of zero.

Data Type

Integer (Int32)

Example

The following example establishes a secure connection to a server:

```
SmtplibClient1.HostName = strHostName
```

```
SmtplibClient1.Secure = True

nError = SmtplibClient1.Connect()
If nError > 0 Then
    MsgBox "Unable to connect to server " & strHostName, vbExclamation
    Exit Sub
End If

If SmtplibClient1.CertificateStatus <> stCertificateValid Then
    nResult = MsgBox("The server certificate could not be validated" & vbCrLf & _
        "Are you sure you wish to continue?", vbYesNo)

    If nResult = vbNo Then
        SmtplibClient1.Disconnect
        Exit Sub
    End If
End If

SmtplibClient1.Disconnect
```

See Also

[CertificateExpires Property](#), [CertificateIssued Property](#), [CertificateIssuer Property](#), [CertificateSubject Property](#), [Secure Property](#)

CertificateStore Property

Gets and sets the name of the client certificate store or file.

Syntax

object.CertificateStore [= *store*]

Remarks

This property sets the name of the certificate store that contains the client certificate that should be used when establishing a secure connection with the server. The certificate may either be stored in the registry or in a file. If the certificate is stored in the registry, then this property should be set to one of the following predefined values:

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. If a certificate store is not specified, this is the default value that is used.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

In most cases the client certificate will be installed in the user's personal certificate store, and therefore it is not necessary to set this property value because that is the default location that will be used to search for the certificate. This property is only used if the **CertificateName** property is also set to a valid certificate name.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU" for the current user, or "HKLM" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, it will default to the certificate store for the current user.

This property may also be used to specify a file that contains the client certificate. In this case, the property should specify the full path to the file and must contain both the certificate and private key in PKCS #12 format. If the file is protected by a password, the **CertificatePassword** property must also be set to specify the password.

Data Type

String

See Also

[CertificateName Property](#), [CertificatePassword Property](#), [Secure Property](#)

CertificateSubject Property

Returns information about the organization that the server certificate was issued to.

Syntax

`object.CertificateSubject`

Remarks

The **CertificateSubject** property returns a string that contains information about the organization that the server certificate was issued for. The string value is a comma separated list of tagged name and value pairs. In the nomenclature of the X.500 standard, each of these pairs are called a relative distinguished name (RDN), and when concatenated together, forms the subject's distinguished name (DN). For example:

C=US, O="RSA Data Security, Inc.", OU=Secure Server Certification Authority

To obtain a specific value, such as the name of the subject's company or country, the application must parse the string returned by this property. Some of the common tokens used in the distinguished name are:

Name	Description
C	The ISO standard two character country code
S	The name of the state or province
L	The name of the city or locality
O	The name of the company or organization
OU	The name of the department or organizational unit
CN	The common name; with X.509 certificates, this is the domain name of the site the certificate was issued for

This property will return an empty string if a secure connection has not been established with the server.

Data Type

String

Example

The following example demonstrates how to extract the value of a relative distinguished name token:

```
Function GetCertNameValue(ByVal strValue As String, ByVal strFieldName As String)
As String
    Dim strFieldValue As String
    Dim cchValue As Integer, cchFieldName As Integer
    Dim nOffset As Integer

    GetCertNameValue = ""
    cchValue = Len(strValue)
    cchFieldName = Len(strFieldName)

    If cchValue = 0 Or cchFieldName = 0 Then
        Exit Function
    End If
```

```

nOffset = InStr(strValue, strFieldName & "=")

If nOffset > 0 Then
    '
    ' If the field name was found in the string, then
    ' remove everything to the left of the token from
    ' the string
    '
    strFieldValue = Right(strValue, cchValue - (nOffset + cchFieldName))

    '
    ' If the value is quoted, then strip off the leading
    ' quote and look for the ending quote in the string;
    ' otherwise look for the comma that marks the end of
    ' the field name/value pair
    '

    If Left(strFieldValue, 1) = Chr(34) Then
        strFieldValue = Right(strFieldValue, Len(strFieldValue) - 1)
        nOffset = InStr(strFieldValue, Chr(34))
    Else
        nOffset = InStr(strFieldValue, ",")
    End If

    '
    ' If the offset is 0, then the name/value pair is
    ' the last token in the string; otherwise, remove
    ' everything to the right of that position
    '

    If nOffset > 0 Then
        strFieldValue = Left(strFieldValue, nOffset - 1)
    End If

    GetCertNameValue = strFieldValue
End If

```

End Function

This function could then be used to return the domain name that the server certificate was issued for:

```

Dim strSubject As String
Dim strDomainName As String

strSubject = SmtplibClient1.CertificateSubject
If Len(strSubject) = 0 Then
    MsgBox "A secure connection has not been established"
Else
    strDomainName = GetCertNameValue(strSubject, "CN")
    MsgBox "This certificate was issued for " & strDomainName
End If

```

See Also

[CertificateExpires Property](#), [CertificateIssued Property](#), [CertificateIssuer Property](#), [CertificateStatus Property](#), [Secure Property](#)

CertificateUser Property

Gets and sets the user that owns the client certificate.

Syntax

object.CertificateUser [= *username*]

Remarks

This property sets the name of the user that owns the client certificate that will be used to establish a secure connection with the server. If this property is not set, the certificate store for the current user will be used when searching for the certificate. If this property is used to specify another user, the process must have the appropriate permission to access the registry location that contains the client certificate. On Windows Vista and later versions of the operating system, this requires that the process run with elevated privileges.

Data Type

String

See Also

[CertificateName Property](#), [CertificateStore Property](#), [Secure Property](#)

CipherStrength Property

Return the length of the key used by the encryption algorithm.

Syntax

object.CipherStrength

Remarks

The **CipherStrength** property returns the number of bits in the key used to encrypt the secure data stream. Common values returned by this property are 128 and 256. A key length of 40-bits or 56-bits is considered to be insecure, and subject to brute force attacks. 128-bit and 256-bit keys are considered secure. If this property returns a value of 0, this means that a secure connection has not been established with the server.

Data Type

Integer (Int32)

See Also

[HashStrength Property](#), [Secure Property](#), [SecureCipher Property](#), [SecureHash Property](#), [SecureKeyExchange Property](#), [SecureProtocol Property](#)

CurrentDate Property

Return the current date in the standard format used by email messages.

Syntax

object.CurrentDate

Remarks

The **CurrentDate** property returns the current date and time in a format that is commonly used in email messages.

Data Type

String

Extended Property

Enable support for extended SMTP commands.

Syntax

object.**Extended** [= { True | False }]]

Remarks

The **Extended** property determines if the control should attempt to use extended SMTP commands. This is required to support options such as authentication, delivery status notification and message sizing.

Note that this property should be set before establishing a connection with the server using the **Connect** method. If the server does not support extended (ESMTP) features, the property value will be reset to False after the connection has been made.

Data Type

Boolean

See Also

[Connect Method](#)

HashStrength Property

Return the length of the message digest that was selected.

Syntax

object.HashStrength

Remarks

The **HashStrength** property returns the number of bits used in the message digest (hash) that was selected. Common values returned by this property are 128 and 160. If this property returns a value of 0, this means that a secure connection has not been established with the server.

Data Type

Integer (Int32)

See Also

[CipherStrength Property](#), [Secure Property](#), [SecureCipher Property](#), [SecureHash Property](#), [SecureKeyExchange Property](#), [SecureProtocol Property](#)

HostAddress Property

Gets and sets the IP address of the server.

Syntax

object.HostAddress [= *ipaddress*]

Remarks

The **HostAddress** property can be used to set the IP address for a server that you wish to communicate with. If the address is valid and matches an entry in the host table, the **HostName** property will be changed to match the address.

Data Type

String

See Also

[AutoResolve Property](#), [HostName Property](#)

HostName Property

Gets and sets the name of the server.

Syntax

object.HostName [= *hostname*]

Remarks

The **HostName** property should be set to the name of the server that you wish to communicate with. If the name is found in the host table, the **HostAddress** property is updated to reflect the IP address of the host.

Note that it is legal to assign an IP address to this property, but it is not legal to assign a host name to the **HostAddress** property.

Data Type

String

See Also

[AutoResolve Property](#), [HostAddress Property](#)

IsBlocked Property

Return if the control is blocked performing an operation.

Syntax

object.IsBlocked

Remarks

The **IsBlocked** property returns True if the specified control is blocked performing an operation. Because the Windows Sockets API only permits one blocking operation per thread of execution, this property should be checked before starting any blocking operation.

Note that this property will return True if there is *any* blocking operation being performed by the application, regardless if the specified control is responsible for the blocking operation or not.

Data Type

Boolean

See Also

[Blocking Property](#), [LastError Property](#)

IsConnected Property

Determine if the control is connected to a server.

Syntax

object.**IsConnected**

Remarks

The **IsConnected** read-only property is set to a value of true if the control is connected with a server, otherwise the property has a value of false.

Data Type

Boolean

IsInitialized Property

Determine if the control has been initialized.

Syntax

object.IsInitialized

Remarks

The **IsInitialized** property is used to determine if the current instance of the control has been initialized properly. Normally this is done automatically when the control is loaded, however there are circumstances where the control may not be able to initialize itself. If this property returns **False**, the application must call the **Initialize** method to initialize the control before performing any other operation.

The most common reason that the control may not initialize correctly is that no valid development or runtime license key can be found or the license key that was provided is invalid. It may also indicate a problem with the system configuration or user access rights, such as not being able to load the required networking libraries or not being able to access the system registry.

Data Type

Boolean

See Also

[Initialize Method](#)

IsWritable Property

Return if data can be sent to the server without blocking.

Syntax

object.IsWritable

Remarks

The **IsWritable** property returns True if data can be written without blocking. For non-blocking connections, this property can be checked before the application attempts to send data to the server, preventing an error.

If the **IsWritable** property returns False, this means that the application cannot write to the socket at that time. However, if the property returns True, this does not guarantee that you will be able to send data without an error. The next operation may result in an **stErrorOperationWouldBlock** or **stErrorOperationInProgress** error. The application must treat these errors as recoverable, and should be prepared to retry operations that result in them.

Data Type

Boolean

See Also

[Write Method](#)

LastError Property

Gets and sets the last error that occurred on the control.

Syntax

object.LastError [= *value*]

Remarks

The **LastError** property can be read to determine the last error that occurred for this control. If a value is assigned to this property, it must either be zero to clear the error or a valid error code for the control.

Data Type

Integer (Int32)

See Also

[LastErrorString Property](#), [OnError Event](#)

LastErrorString Property

Return a description of the last error to occur.

Syntax

object.LastErrorString

Remarks

The **LastErrorString** property returns a description of the last error that occurred. This can be used to display a meaningful error message to a user, rather than just the numeric value returned by the **LastError** property.

Data Type

String

See Also

[LastError Property](#), [OnError Event](#)

LocalDomain Property

Gets and sets the local domain name.

Syntax

object.LocalDomain [= *domain*]

Remarks

The **LocalDomain** returns the local domain name used when the client identifies itself to the mail server. If this property is an empty string, then the control will attempt to automatically determine the appropriate domain name to use based on the system configuration. Setting this property will cause the control to use that value when identifying itself to the server.

This property should only be set if it is absolutely necessary. In most cases, it is preferable to leave this property undefined and allow the control to automatically determine the correct domain name to use. Setting an invalid domain name may cause the mail server to reject the connection.

Data Type

String

See Also

[HostName Property](#)

Options Property

Gets and sets the options that are used in establishing a connection.

Syntax

object.Options [= *options*]

Remarks

The **Options** property is an integer value which specifies one or more options. The value specified for this property will be used as the default options when connecting to the server. The property value is created by using a bitwise operator with one or more of the following values:

Value	Description
smtpOptionNone	No additional options are specified when establishing a connection with the server. A standard, non-secure connection will be used and the client will not attempt to use extended (ESMTP) features of the protocol. Note that if the mail server requires authentication, the smtpOptionExtended option must be specified.
smtpOptionExtended	Extended SMTP commands should be used if possible. This option enables features such as authentication and delivery status notification. If this option is not specified, the library will not attempt to use any extended features. This option is automatically enabled if the connection is established on port 587 because submitting messages for delivery using this port typically requires client authentication.
smtpOptionTunnel	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
smtpOptionTrustedSite	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
smtpOptionSecureExplicit	This option specifies that a secure connection should be established with the server and requires that the server support the TLS protocol. This option initiates the secure session using the STLS command.
smtpOptionSecureImplicit	This option specifies the client should attempt to establish a secure connection with the server. It should only be used when the server expects an implicit TLS connection or does not implement RFC 2595 where the STLS command is used to negotiate a secure connection with the server.
smtpOptionSecureFallback	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this

	option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
smtpOptionPreferIPv6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.

Data Type

Integer (Int32)

See Also

[Extended Property](#), [Secure Property](#), [Connect Method](#)

Password Property

Gets and sets the password for the current user.

Syntax

object.Password [= *password*]

Remarks

The **Password** property specifies the password used to authenticate the user. This property is used as the default value for the **Authenticate** method if no password is specified as an argument.

Refer to the **AuthType** property for more information on the available authentication methods. If you are using the OAuth 2.0 authentication method, this property should not be set to the user's password. Instead, you should set the **BearerToken** property to the OAuth 2.0 access token issued by the mail service provider. Note that these access tokens can be much larger than your typical password and are only valid for a limited period of time.

You can use the **Password** property to specify an OAuth 2.0 bearer token. However, it is recommended that you use the **BearerToken** property instead of assigning it to this property. It will ensure compatibility with future versions of the control and make it clear in your code you are using an OAuth 2.0 bearer token and not a password. If the **AuthType** property specifies one of the OAuth 2.0 authentication methods, this property will return the bearer token.

Data Type

String

See Also

[BearerToken Property](#), [UserName Property](#), [Authenticate Method](#), [Connect Method](#)

RemotePort Property

Gets and sets the port number for a remote connection.

Syntax

object.RemotePort [= *portnumber*]

Remarks

The **RemotePort** property is used to set the port number that the control will use to establish a connection with the server. For standard connections, the default port number is 25. An alternative port is 587, which is commonly used by authenticated clients to submit messages for delivery. For secure connections, the default port number is 465. If the secure port number is specified, an implicit TLS connection will be established by default.

Data Type

Integer (Int32)

See Also

[HostAddress Property](#), [HostName Property](#)

ResultCode Property

Return the result code of the previous action.

Syntax

object.ResultCode

Remarks

The **ResultCode** read-only property returns the result code of the last action performed by the client. This property should be checked after the **Command** method is used to execute a command on the server to determine if the operation was successful. Result codes are three-digit numeric values returned by the server and may be broken down into the following ranges:

Value	Description
100-199	Positive preliminary result. This indicates that the requested action is being initiated, and the client should expect another reply from the server before proceeding.
200-299	Positive completion result. This indicates that the server has successfully completed the requested action.
300-399	Positive intermediate result. This indicates that the requested action cannot complete until additional information is provided to the server.
400-499	Transient negative completion result. This indicates that the requested action did not take place, but the error condition is temporary and may be attempted again.
500-599	Permanent negative completion result. This indicates that the requested action did not take place.

It is important to note that while some result codes have become standardized, not all servers respond to commands using the same result codes. For example, one server may respond with a result code of 221 to indicate success, while another may respond with a value of 235. It is recommended that applications check for ranges of values to determine if a command was successful, not a specific value.

Data Type

Integer (Int32)

See Also

[ResultString Property](#), [Command Method](#), [OnCommand Event](#)

ResultString Property

Return a string describing the results of the previous action.

Syntax

object.ResultString

Remarks

The **ResultString** read-only property returns the result string from the last action taken by the client. This string is generated by the server, and typically is used to describe the result code. For example, if an error is indicated by the result code, the result string may describe the condition that caused the error.

Data Type

String

See Also

[ResultCode Property](#), [Command Method](#), [OnCommand Event](#)

ReturnReceipt Property

Enable or disable delivery status notification.

Syntax

`object.ReturnReceipt [= { True | False } ] ]`

Remarks

The **ReturnReceipt** property enables or disables delivery status notification (DSN) by the mail server. If the property is set to True, a mail message will be automatically returned to the sender indicating if the message was delivered successfully, unsuccessfully or delayed by the mail server. If the property is set to False, no delivery status information is sent back to the sender.

Note that delivery status notification is not available on all servers. It is also important to note that a message indicating that delivery was successful does not mean that the message was actually read by the recipient, only that it was delivered to their mailbox.

Data Type

Boolean

See Also

[AddRecipient Method](#), [CreateMessage Method](#)

Secure Property

Set or return if a connection to the server is secure.

Syntax

object.Secure [= { True | False }]

Remarks

The **Secure** property determines if a secure connection is established to the server. The default value for this property is False, which specifies that a standard connection to the server is used. To establish a secure connection, the application must set this property value to True prior to calling the **Connect** method. Once the connection has been established, the client may request files or submit queries to the server as with standard connections.

It is strongly recommended that any application that sets this property True use error handling to trap an errors that may occur. If the control is unable to initialize the security libraries, or otherwise cannot create a secure session for the client, an error will be generated when this property value is set.

Data Type

Boolean

Example

The following example establishes a secure connection to a server:

```
SmtplibClient1.HostName = strHostName
SmtplibClient1.RemotePort = 587
SmtplibClient1.UserName = strUserName
SmtplibClient1.Password = strPassword
SmtplibClient1.Secure = True

nError = SmtplibClient1.Connect()
If nError > 0 Then
    MsgBox "Unable to connect to server " & strHostName, vbExclamation
    Exit Sub
End If

If SmtplibClient1.CertificateStatus <> stCertificateValid Then
    nResult = MsgBox("The server certificate could not be validated" & vbCrLf & _
        "Are you sure you wish to continue?", vbYesNo)

    If nResult = vbNo Then
        SmtplibClient1.Disconnect
        Exit Sub
    End If
End If
```

See Also

[CertificateStatus Property](#), [Connect Method](#)

SecureCipher Property

Return the encryption algorithm used to establish the secure connection with the server.

Syntax

object.SecureCipher

Remarks

The **SecureCipher** property returns an integer value which identifies the algorithm used to encrypt the data stream. This property may return one of the following values:

Value	Description
stCipherNone	No cipher has been selected. This is not a secure connection with the server.
stCipherRC2	The RC2 block cipher was selected. This is a variable key length cipher which supports keys between 40- and 128-bits in length, in 8-bit increments.
stCipherRC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40- and 128-bits in length, in 8-bit increments.
stCipherRC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.
stCipherDES	The DES (Data Encryption Standard) block cipher was selected. This is a fixed key length cipher using 56-bit keys.
stCipherDES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively using a 168-bit key length.
stCipherDESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.
stCipherAES	The Advanced Encryption Standard cipher (also known as the Rijndael cipher) is a fixed block size cipher which use a key size of 128, 192 or 256 bits. This cipher is supported on Windows XP SP3 and later versions of the operating system.
stCipherSkipjack	The Skipjack block cipher was selected. This is a fixed key length cipher, using 80-bit keys.
stCipherBlowfish	The Blowfish block cipher was selected. This is a variable key length cipher up to 448 bits, using a 64-bit block size.

If a secure connection has not been established, this property will return a value of zero.

Data Type

Integer (Int32)

See Also

[CipherStrength Property](#), [HashStrength Property](#), [Secure Property](#), [SecureHash Property](#), [SecureKeyExchange Property](#), [SecureProtocol Property](#)

SecureHash Property

Return the message digest selected when establishing the secure connection with the server.

Syntax

object.SecureHash

Remarks

The **SecureHash** property returns an integer value which identifies the message digest algorithm that was selected when a secure connection is established. This property may return one of the following values:

Value	Description
stHashMD5	The MD5 algorithm was selected. This algorithm has been deprecated and is no longer considered to be cryptographically secure.
stHashSHA1	The SHA-1 algorithm was selected. This algorithm has been deprecated and is no longer considered to be cryptographically secure.
stHashSHA256	The SHA-256 algorithm has been selected.
stHashSHA384	The SHA-384 algorithm has been selected.
stHashSHA512	The SHA-512 algorithm has been selected.

If a secure connection has not been established, this property will return a value of zero.

Data Type

Integer (Int32)

See Also

[CipherStrength Property](#), [HashStrength Property](#), [Secure Property](#), [SecureCipher Property](#), [SecureKeyExchange Property](#), [SecureProtocol Property](#)

SecureKeyExchange Property

Return the key exchange algorithm used to establish the secure connection with the server.

Syntax

`object.SecureKeyExchange`

Remarks

The **SecureKeyExchange** property returns an integer value which identifies the key-exchange algorithm used when establishing a secure connection. This property may return one of the following values:

Value	Description
stKeyExchangeNone	No key exchange algorithm has been selected. This is not a secure connection with the server.
stKeyExchangeRSA	The RSA public key exchange algorithm has been selected.
stKeyExchangeKEA	The KEA public key exchange algorithm has been selected. This is an improved version of the Diffie-Hellman public key algorithm.
stKeyExchangeDH	The Diffie-Hellman public key exchange algorithm has been selected.
stKeyExchangeECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography. This key exchange algorithm is only supported on Windows XP SP3 and later versions of the operating system.

If a secure connection has not been established, this property will return a value of zero.

Data Type

Integer (Int32)

See Also

[CipherStrength Property](#), [HashStrength Property](#), [Secure Property](#), [SecureCipher Property](#), [SecureHash Property](#), [SecureProtocol Property](#)

SecureProtocol Property

Gets and sets the security protocol used to establish the secure connection with the server.

Syntax

object.SecureProtocol [= *protocol*]

Remarks

The **SecureProtocol** property can be used to specify the security protocol to be used when establishing a secure connection with a server. By default, the control will attempt to use TLS 1.3 to establish the connection. If TLS 1.3 is not supported, TLS 1.2 will be used. The appropriate protocol is automatically selected based on the capabilities of both the client and server.

It is recommended that you only change this property value if you fully understand the implications of doing so. Assigning a value to this property will override the default and force the control to attempt to use only the protocol specified. One or more of the following values may be used:

Value	Description
stProtocolNone	No security protocol has been selected. A secure connection has not been established.
stProtocolTLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
stProtocolTLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
stProtocolTLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
stProtocolTLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

Multiple security protocols may be specified by combining them using a bitwise Or operator. After a connection has been established, reading this property will identify the protocol that was selected to establish the connection. Attempting to set this property after a connection has been established will result in an exception being thrown. This property should only be set after setting the **Secure** property to True and before calling the **Connect** method.

Data Type

Integer (Int32)

See Also

[CipherStrength Property](#), [HashStrength Property](#), [Secure Property](#), [SecureCipher Property](#), [SecureHash Property](#), [SecureKeyExchange Property](#)

ThrowError Property

Enables or disables error handling by the application.

Syntax

object.ThrowError = { True | False }

Remarks

Error handling for methods can be performed using either return codes or exceptions, depending on the value of this property.

If the **ThrowError** property is set to False, methods will return a status value indicating success or failure. Applications should check the return value of each method and use the **LastError** and **LastErrorString** properties to determine the cause of any error.

If the **ThrowError** property is set to True, errors occurring within the control will be raised to the host application as ActiveX exceptions. In addition, the **OnError** event will fire. This allows applications to use language-specific exception handling mechanisms, such as Visual Basic error handling, instead of checking individual return values after each method call.

Even when the **ThrowError** property is set to True, the **LastError** and **LastErrorString** properties will still be updated with information about the most recent error.

If an error occurs while accessing a property value, an exception will be raised regardless of the value of the **ThrowError** property. However, the **OnError** event will not be fired for property access errors.

Data Type

Boolean

Example

The following example handles errors by checking the return code of a method:

```
SmtplibClient1.ThrowError = False
nError = SmtplibClient1.Connect(strHostName)

If nError > 0 Then
    MsgBox SmtplibClient1.LastErrorString, vbExclamation
    Exit Sub
End If
```

The following example handles errors by throwing them to the container:

```
On Error Resume Next: Err.Clear

SmtplibClient1.ThrowError = True
SmtplibClient1.Connect strHostName

If Err.Number <> 0
    MsgBox Err.Description, vbExclamation
    Exit Sub
End If
On Error GoTo 0
```

See Also

[LastError Property](#), [LastErrorString Property](#), [OnError Event](#)

Timeout Property

Gets and sets the amount of time until a blocking operation fails.

Syntax

object.Timeout [= *seconds*]

Remarks

Setting the **Timeout** property specifies the number of seconds until a blocking operation fails and the control returns an error.

Note that the **Timeout** property also determines the amount of time the control will spend attempting to connect to a server. If a connection is not established within the given time period, the connection attempt will fail.

Data Type

Integer (Int32)

Trace Property

Enable or disable network function level logging.

Syntax

`object.Trace [= { True | False } ]`

Remarks

The **Trace** property is used to enable or disable the logging of network function calls. When enabled, each function call is logged to a file, including the function parameters, return value and error code if applicable. This facility can be enabled and disabled at run time, and the trace log file can be specified by setting the **TraceFile** property. All function calls that are being logged are appended to the trace file, if it exists. If no log file exists when tracing is enabled, the file is created.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

Data Type

Boolean

See Also

[TraceFile Property](#), [TraceFlags Property](#)

TraceFile Property

Gets and sets the name of the file to use when logging network function calls.

Syntax

`object.TraceFile [= filename ]`

Remarks

The **TraceFile** property is used to specify the name of the file that is created when logging is enabled. If this property is set to an empty string (the default value), then a file named **SocketTools.log** is created in the current user's Documents folder. It is recommended that you always specify a complete path to the log file. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

If the file exists, the output is appended to the file, otherwise the file is created. Since logging is enabled per-process, the log file is shared by all instances of the controls being used. If you create multiple instances of the control, you only need to enable logging for a single instance. Because log files can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "0x". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxx:xxxx:xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, the control is attempting to connect to a system with the IPv4 address 192.0.0.1 on port 1234.

If the log file cannot be created, or the user does not have permission to modify an existing file, the error is silently ignored and no output will be generated.

Data Type

String

See Also

TraceFlags Property

Gets and sets the network function logging flags.

Syntax

object.TraceFlags [= *flags*]

Remarks

The **TraceFlags** property is used to specify the type of information written to the trace file when socket function tracing is enabled. The following values may be used:

Value	Description
dnsTraceInfo	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
dnsTraceError	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
dnsTraceWarning	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
dnsTraceHexDump	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
dnsTraceTruncate	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.

Since logging is enabled per-process, the trace flags are shared by all instances of the control being used. If multiple controls have tracing enabled, the **TraceFlags** property should be set to the same value for each control. Changing the trace flags for any one instance of the control will affect the logging performed for all other instances used by the application.

Warnings are generated when a non-fatal error is returned by a Windows Sockets function. For example, if data is being written through the control and an error indicating that the operation would block is returned, only a warning is logged since the application simply needs to attempt to write the data at a later time.

Data Type

Integer (Int32)

See Also

[Trace Property](#), [TraceFile Property](#)

UserName Property

Gets and sets the current user name.

Syntax

object.UserName [= *username*]

Remarks

The **UserName** property specifies the user that is logging in to the server, and is required for authentication purposes. This property is used as the default value for the **Connect** method if no password is specified as an argument.

Data Type

String

See Also

[Password Property](#), [Connect Method](#)

Version Property

Return the current version of the control.

Syntax

object.Version

Remarks

The **Version** property returns the current version of the object. This can be used by an application for validation purposes. The version returned is composed of four numbers, separated by periods. The first number is the major version number, the second number is the minor version number, the third is the build number and the fourth is the revision number.

Data Type

String

Simple Mail Transfer Protocol Control Methods

Method	Description
AddRecipient	Add an address to the recipient list for the current message
AppendMessage	Append text to the current message being composed
Authenticate	Authenticate the client session
Cancel	Cancels the current blocking network operation
CloseMessage	Closes the current message
Command	Send a custom command to the server
Connect	Establish a connection with a server
CreateMessage	Begin the composition of a new message to be delivered
Disconnect	Terminate the connection with a server
ExpandAddress	Expand the specified email address
Initialize	Initialize the control and validate the runtime license key
Reset	Reset the internal state of the control
SendMessage	Send the specified message through the mail server
Uninitialize	Uninitialize the control and release any system resources that were allocated
VerifyAddress	Verify the specified email address
Write	Write data to the server

AddRecipient Method

Add an address to the recipient list for the current message.

Syntax

object.AddRecipient(*Address*)

Parameters

Address

A string value that specifies the email address of a recipient.

Return Value

A value of zero is returned if the operation was successful, otherwise a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **AddRecipient** method adds the specified address to the recipient list for the current message. This method should be called after the message transaction has begun with a call to the **CreateMessage** method. Most servers impose a limit of approximately 100 recipient addresses that will be accepted for a single message.

See Also

[AppendMessage Method](#), [CloseMessage Method](#), [CreateMessage Method](#)

AppendMessage Method

Append text to the current message being composed.

Syntax

object.AppendMessage(*Message*, [*Options*])

Parameters

Message

A string or byte array which will contain the article to be posted to the server.

Options

An optional integer value which specifies one or more options. This argument is reserved for future use and should be omitted.

Return Value

A value of zero is returned if the operation was successful, otherwise a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **AppendMessage** method appends the specified text to the current message. This method will cause the current thread to block until the article transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

This method is useful for composing a message where the application needs to dynamically create the header, followed by a large amount of text. The message contents should be text, with each line terminated with a carriage return and linefeed character. Not all mail servers support sending 8-bit characters, so the message contents may need to be encoded if it uses anything other than standard US ASCII. To append binary data, it must be encoded using either the uuencode or base64 (MIME) algorithms. It is recommended that you use the Mail Message control to handle file attachments and other complex message types.

See Also

[AddRecipient Method](#), [CloseMessage Method](#), [CreateMessage Method](#)

Authenticate Method

Authenticate the client session.

Syntax

object.Authenticate([*UserName*], [*Password*])

Parameters

UserName

An optional string argument which specifies the username used to authenticate the client session. If the argument is omitted, the value assigned to the **UserName** property will be used instead.

Password

An optional string argument which specifies the password used to authenticate the client session. If the argument is omitted, the value assigned to the **Password** property will be used instead. If you are using OAuth 2.0 authentication, this parameter specifies the bearer token provided by the mail service.

Return Value

A value of zero is returned if the operation was successful, otherwise a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **Authenticate** method is used to authenticate the current client session to the mail server, ensuring that only valid users may deliver messages through the server. This method uses the LOGIN authentication mechanism by default and you can specify an alternate authentication method by setting the **AuthType** property.

Authentication requires the server to support the AUTH extended SMTP command and the **Extended** property must be set to True. If the server does not support the specified type of authentication, an error will be returned.

If you wish to use OAuth 2.0 for authentication, set the **AuthType** property to the desired authentication type prior to calling this method. The connection must be secure, and the server must advertise its support for OAuth 2.0 or the authentication attempt will fail. This method will not attempt to automatically refresh an expired token.

See Also

[AuthType Property](#), [BearerToken Property](#), [Password Property](#), [UserName Property](#), [Connect Method](#)

Cancel Method

Cancels the current blocking network operation.

Parameters

None.

Return Value

None.

Remarks

The **Cancel** method cancels any blocking network operation in the current thread. This is typically used inside an event handler, causing the blocking method to return to the caller with an error indicating that the current operation was canceled. This method sets an internal flag that is periodically checked during a blocking operation, such as waiting for more data to arrive. If the current thread is not blocked at the time that this method is called, it will have no effect.

See Also

[Disconnect Method](#), [Reset Method](#), [OnCancel Event](#)

CloseMessage Method

Closes the current message.

Syntax

object.CloseMessage

Parameters

None.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **CloseMessage** method closes the current message and completes the submission of the message to the server. This method is only required if the message is being submitted using the **AppendMessage** or **Write** methods.

See Also

[AppendMessage Method](#), [CreateMessage Method](#)

Command Method

Send a custom command to the server.

Syntax

object.Command(Command, [Parameters], [Options])

Parameters

Command

A string which specifies the command to send. Valid commands vary based on the Internet protocol and the type of server that the client is connected to. Consult the protocol standard and/or the technical reference documentation for the server to determine what commands may be issued by a client application.

Parameters

An optional string which specifies one or more parameters to be sent along with the command. If more than one parameter is required, most Internet protocols require that they be separated by a single space character. Consult the protocol standard and/or technical reference documentation for the server to determine what parameters should be provided when issuing a specific command. If no parameters are required for the command, this argument may be omitted.

Options

A numeric value which specifies one or more options. Currently this argument is reserved and should either be omitted, or a value of zero should always be used.

Return Value

A value of zero is returned if the command was successful. Otherwise, a non-zero error code is returned which indicates the cause of the failure. To determine the result code returned by the server in response to the command, read the value of the **ResultCode** property.

Remarks

The **Command** method sends a command to the server and processes the result code sent back in response to that command. This method can be used to send custom commands to a server to take advantage of features or capabilities that may not be supported internally by the control.

See Also

[ResultCode Property](#), [ResultString Property](#), [OnCommand Event](#)

Connect Method

Establish a connection with a server.

Syntax

`object.Connect( [RemoteHost], [RemotePort], [UserName], [Password], [Timeout], [Options] )`

Parameters

RemoteHost

A string which specifies the host name or IP address of the server. If this argument is not specified, it defaults to the value of the **HostAddress** property if it is defined. Otherwise, it defaults to the value of the **HostName** property.

RemotePort

A number which specifies the port to connect to on the server. If this argument is not specified, it defaults to the value of the **RemotePort** property. A value of zero specifies that the default port number should be used. For standard connections, the default port number is 25. An alternative port is 587, which is commonly used by authenticated clients to submit messages for delivery. For implicit TLS connections, the default port number is 465.

UserName

An optional string argument which specifies the user name to be used with authentication. If this argument is not specified, it defaults to the value of the **UserName** property. Note that for authentication to be performed, the **Extended** property must be set to True.

Password

An optional string argument which specifies the password to be used with authentication. If this argument is not specified, it defaults to the value of the **Password** property. Note that for authentication to be performed, the **Extended** property must be set to True.

Timeout

The number of seconds that the client will wait for a response before failing the operation. If this argument is not specified, the value of the **Timeout** property will be used as the default.

Options

A numeric value which specifies one or more options. If this argument is omitted or a value of zero is specified, a default connection will be established. This argument is constructed by using a bitwise operator with any of the following values:

Value	Description
smtpOptionNone	No additional options are specified when establishing a connection with the server. A standard, non-secure connection will be used and the client will not attempt to use extended (ESMTP) features of the protocol. Note that if the mail server requires authentication, the smtpOptionExtended option must be specified.
smtpOptionExtended	Extended SMTP commands should be used if possible. This option enables features such as authentication and delivery status notification. If this option is not specified, the library will not attempt to use any extended features. This option is automatically enabled if the connection is established on port

	587 because submitting messages for delivery using this port typically requires client authentication.
smtpOptionTunnel	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
smtpOptionTrustedSite	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
smtpOptionSecureExplicit	This option specifies that a secure connection should be established with the server and requires that the server support the TLS protocol. This option initiates the secure session using the STLS command.
smtpOptionSecureImplicit	This option specifies the client should attempt to establish a secure connection with the server. It should only be used when the server expects an implicit TLS connection or does not implement RFC 2595 where the STLS command is used to negotiate a secure connection with the server.
smtpOptionSecureFallback	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
smtpOptionPreferIPv6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.

Return Value

A value of zero is returned if the connection was successful. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **Connect** method establishes a connection with the mail server. All arguments are optional. If a given argument is omitted, then the corresponding property values are used as defaults. Specifying a username and password only sets the default **UserName** and **Password** property values. If authentication is required, the client must explicitly call the **Authenticate** method after the connection has been established.

See Also

[Extended Property](#), [HostAddress Property](#), [HostName Property](#), [Options Property](#), [RemotePort](#)

CreateMessage Method

Begin the composition of a new message to be delivered.

Syntax

object.CreateMessage(*Sender*, [*MessageSize*])

Parameters

Sender

A string which specifies the email address of the user sending the message. This typically corresponds to the address in the From header of the message, but it is not required that they be the same.

MessageSize

An integer which specifies the size of the message in bytes. If the size of the message is unknown, this argument should be omitted or passed as value of zero. This argument is ignored if the server does not support extended features. If the message size is larger than what the server will accept, this method will fail. Most Internet Service Providers impose a limit on the size of an email message, typically between 5 and 10 megabytes.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **CreateMessage** method begins the composition of a new message to be submitted to the mail server for delivery. There are several steps that must be followed when dynamically composing a message using the **CreateMessage** method:

1. Call the **CreateMessage** method to begin the message composition. The sender email address should generally be the same address as the one used in the "From" header field in the message.
2. Call the **AddRecipient** method for each recipient of the message. These addresses are typically specified in the "To" and "Cc" header fields in the message. Additional addresses may also be provided which are not specified in the email message itself. This is how one or more blind carbon copies of a message is delivered. Most servers have a limit on the total number of recipients that may be specified for a single message. This limit is usually around 100 addresses.
3. Call the **Write** method to write the contents of the message to the data stream. The application may also choose to use the **AppendMessage** method to write out a large amount of message data.
4. Call the **CloseMessage** method to close the message and submit it to the mail server for delivery.

For applications that do not need to dynamically compose the message and already have the message contents stored in a file or memory buffer, the **SendMessage** method is the preferred method of submitting a message for delivery.

See Also

[AddRecipient Method](#), [AppendMessage Method](#), [CloseMessage Method](#), [SendMessage Method](#),
[Write Method](#)

Disconnect Method

Terminate the connection with a server.

Syntax

object.Disconnect

Parameters

None.

Return Value

A value of zero is returned if the connection was terminated successfully. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

This method terminates the network connection with the server.

See Also

[IsConnected Property](#), [Connect Method](#), [OnDisconnect Event](#)

ExpandAddress Method

Expand the specified email address.

Syntax

object.ExpandAddress(*Address*, *ExpandedAddress*)

Parameters

Address

A string argument which specifies the address to expand.

ExpandedAddress

A string argument which will contain the list of expanded addresses when the method returns.

Return Value

If the method succeeds, it will return a value of true. If it was unable to expand the address, then the return value will be False. If the method fails, the **ResultString** property may provide additional information as to why the failure occurred.

Remarks

The **ExpandAddress** method requests that the server expand the specified email address. Typically this is used to expand aliases which refer to a mailing list, returning all of the members of that list. A server may not support this command, or may restrict its usage. An application should not depend on the ability to expand addresses.

See Also

[VerifyAddress Method](#)

Initialize Method

Initialize the control and validate the runtime license key.

Syntax

```
object.Initialize( [LicenseKey] )
```

Parameters

LicenseKey

An optional string value which specifies a runtime license key used to initialize the control. If the license key is omitted or passed as an empty string, a development license must be installed on the local system.

Return Value

A value of zero is returned if the control was initialized successfully. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

This method dynamically loads other system libraries and allocates thread local storage. In most cases, it is not necessary to call this method directly because it is automatically invoked when an instance of the control is created by the container. However, if the control is created dynamically using **CreateObject** or a similar method, this must be the first method that is called before you attempt to modify any property values or invoke other methods. Failure to initialize the control may result in subsequent errors and/or cause an exception to be raised.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the control will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the control was created.

If the control is being used within another DLL, it is important that you do not attempt to create an instance of the control or call the **Initialize** method from within the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is written in C++ and it is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for any static and global C++ objects and has the same restrictions.

Example

```
Set smtpClient = CreateObject("SocketTools.Smtplib.12")

nError = smtpClient.Initialize(strLicenseKey)
If nError > 0 Then
    MsgBox "Unable to initialize SocketTools component"
End
End If
```

See Also

[IsInitialized Property](#), [Uninitialize Method](#)

Reset Method

Reset the internal state of the control.

Syntax

object.Reset

Parameters

None.

Return Value

None.

Remarks

The **Reset** method resets the internal state of the control. Property values are initialized to their internal defaults, open network connections will be closed and any handles allocated by the control will be released.

See Also

[Cancel Method](#), [Initialize Method](#), [Uninitialize Method](#)

SendMessage Method

Submit the specified message to the mail server for delivery.

Syntax

object.SendMessage(*Sender*, *Recipients*, *Message*, [*Options*])

Parameters

Sender

A string argument which specifies the email address of the person sending the message. This typically corresponds to the address in the From header of the message, but it is not required that they be the same.

Recipients

A string argument which specifies the email address of the person or persons to receive the message. Multiple addresses may be specified by separating each address with a comma. It should be noted that this protocol is only concerned with the delivery of a message and not its contents. Header fields in the message are not parsed to automatically determine the recipients. This argument should be a concatenation of all recipients, including carbon copies and blind carbon copies, with each address separated with a comma.

Message

A string argument contains the message to be delivered to the specified recipients. The message must be text and conform to the basic structure defined in RFC 822. There must be one or more headers separated by a blank line, followed by the body of the message. Each line of text must be terminated by a carriage return and linefeed character sequence. Note that more complex multipart MIME messages may also be used, but it is recommended that you use the Mail Message control to compose them.

Options

An optional argument that is reserved for future use. This argument should be omitted when calling this method.

Return Value

A value of zero is returned if the operation was successful, otherwise a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **SendMessage** method enables an application to send a formatted email message using the current mail server. This provides a convenient one-step method of addressing and sending a message, and is designed to easily integrate with the Mail Message control.

This method will cause the current thread to block until the message transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

Example

The following example demonstrates how to use the **SendMessage** method, along with the Mail Message control, to compose and deliver a message:

```
' Compose a new message  
nError = MailMessage1.ComposeMessage(strFrom, _
```

```

        strTo, _
        strCc, _
        strBcc, _
        strSubject, _
        strMessageText)

If nError > 0 Then
    MsgBox MailMessage1.LastErrorString, vbExclamation
    Exit Sub
End If

If MailMessage1.Recipients = 0 Then
    MsgBox "There are no recipients for this message"
    Exit Sub
End If

' Connect to the mail server
nError = SmtpClient1.Connect(strMailServer)
If nError > 0 Then
    MsgBox SmtpClient1.LastErrorString, vbExclamation
    Exit Sub
End If

' Deliver the message
nError = SmtpClient1.SendMessage(MailMessage1.Sender, MailMessage1.AllRecipients,
MailMessage1.Message)
If nError > 0 Then
    MsgBox SmtpClient1.LastErrorString, vbExclamation
    SmtpClient1.Disconnect
    Exit Sub
End If

' Disconnect
SmtpClient1.Disconnect

```

See Also

[AddRecipient Method](#), [Connect Method](#), [CreateMessage Method](#), [Disconnect Method](#), [OnProgress Event](#)

Uninitialize Method

Uninitialize the control and release any system resources that were allocated.

Syntax

object.Uninitialize

Parameters

None.

Return Value

None.

Remarks

The **Uninitialize** method terminates any connection established by the control and resets the internal state of the control. This method is not typically used because any resources that have been allocated by an instance of the control will automatically be released when it is destroyed.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the control will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the control was created. An application should only call the **Uninitialize** method if it has explicitly called the **Initialize** method.

See Also

[Initialize Method](#)

VerifyAddress Method

Verify the specified email address.

Syntax

object.VerifyAddress(*Address*, *VerifiedAddress*)

Parameters

Address

A string argument which specifies the address to verify.

VerifiedAddress

A string argument which will contain the verified address when the method returns. This parameter must be passed by reference.

Return Value

If the method succeeds, it will return a value of true. If it was unable to verify the address, then the return value will be False. If the method fails, the **ResultString** property may provide additional information as to why the failure occurred.

Remarks

The **VerifyAddress** method requests that the server verify the specified email address. Typically this is used to verify that a recipient address is valid, and return a fully qualified email address for that recipient. A server may not support this command, or may restrict its usage. An application should not depend on the ability to verify addresses.

See Also

[ExpandAddress Method](#)

Write Method

Write data to the server.

Syntax

object.Write(*Buffer*, [*Length*])

Parameters

Buffer

A buffer variable that contains the data to be written to the server. If the variable is a **String** type, then the data will be written as a string of characters. This is the most appropriate data type to use if the server expects text data that consists of printable characters. If the string contains Unicode characters, it will be automatically converted to use standard UTF-8 encoding prior to being sent. If you wish to send the data without conversion, use a **Byte** array as the buffer instead of a **String** variable.

Length

A numeric value which specifies the number of bytes to write. Its maximum value is $2^{31}-1 = 2147483647$. If a value is specified for this argument and it is greater than the actual size of the buffer, then the **Length** argument will be ignored and the entire contents of the buffer will be written. If the argument is omitted, then the maximum number of bytes to write is determined by the size of the buffer.

Return Value

This method returns the number of bytes actually written to the server, or -1 if an error was encountered.

Remarks

The **Write** method sends the data in *buffer* to the server. If the connection is buffered, as is typically the case, the data is copied to the send buffer and control immediately returns to the program. If the control is blocking, the application will wait until the data can be sent. If the control is non-blocking and the write fails because it could not send all of the data to the server, the **OnWrite** event will be fired when the server can accept data again.

If the **Write** method is used to send the message contents to the server, the application must first call the **CreateMessage** method to specify the sender and the length of the message, followed by one or more calls to the **AddRecipient** method to specify each recipient of the message. When all of the message text has been submitted to the server, the application must call the **CloseMessage** method.

The message text is filtered by the **Write** method, and it will automatically normalize end-of-line character sequences to ensure the message meets the protocol requirements. The message itself must be in a standard RFC 822 or multi-part MIME message format, or the server may reject the message. Binary data, such as file attachments, should always be encoded. The **MailMessage** control can be used to compose and export a message in the correct format, which can then be submitted to the server.

It is recommended that most applications use the **SendMessage** method, which submits the message in a single method call.

See Also

[AddRecipient Method](#), [CloseMessage Method](#), [CreateMessage Method](#), [SendMessage Method](#)

Simple Mail Transfer Protocol Control Events

Event	Description
OnCancel	This event occurs when a blocking operation is canceled
OnCommand	This event occurs when the server processes a command issued by the client
OnConnect	This event occurs when a connection is established
OnDisconnect	This event occurs when a connection is terminated
OnError	This event occurs when a control error occurs
OnProgress	This event occurs during data transfer
OnTimeout	This event occurs when a blocking operation times out

OnCancel Event

The **OnCancel** event is generated when a blocking operation is canceled.

Syntax

Sub *object_OnCancel* ([*Index As Integer*])

Remarks

This event occurs when a blocking operation on the socket, such as sending or receiving data, is canceled with the **Cancel** method. To assist in determining which operation was canceled, consult the **State** property.

See Also

[Cancel Method](#), [OnError Event](#), [OnTimeout Event](#)

OnCommand Event

The **OnCommand** event is generated when the client sends a command to the server and receives a reply indicating the results of that command.

Syntax

Sub *object_OnCommand*([*Index As Integer*], **ByVal** *ResultCode As Variant*, **ByVal** *ResultString As Variant*)

Remarks

The **OnCommand** event is generated when the client receives a reply from the server after some action has been taken. The **ResultCode** argument contains the numeric result code returned by the server. The result codes returned from the server fall into one of the following categories:

Value	Description
100-199	Positive preliminary result. This indicates that the requested action is being initiated, and the client should expect another reply from the server before proceeding.
200-299	Positive completion result. This indicates that the server has successfully completed the requested action.
300-399	Positive intermediate result. This indicates that the requested action cannot complete until additional information is provided to the server.
400-499	Transient negative completion result. This indicates that the requested action did not take place, but the error condition is temporary and may be attempted again.
500-599	Permanent negative completion result. This indicates that the requested action did not take place.

The **ResultString** argument contains the descriptive string returned by the server which describes the result. The string contents may vary depending on the type of server.

See Also

[ResultCode Property](#), [ResultString Property](#), [Command Method](#)

OnConnect Event

The **OnConnect** event is generated when a connection is established.

Syntax

Sub *object_OnConnect* ([*Index As Integer*])

Remarks

The **OnConnect** event is generated when a connection is made with a server as a result of a **Connect** method call. This event is only triggered when the **Blocking** property is set to False.

See Also

[Blocking Property](#), [Connect Method](#), [OnDisconnect Event](#)

OnDisconnect Event

The **OnDisconnect** event is generated when a connection is terminated.

Syntax

Sub *object_OnDisconnect* ([*Index As Integer*])

Remarks

The **OnDisconnect** event is generated when the connection is terminated by the server. This event is only triggered when the **Blocking** property is set to False.

When the **OnDisconnect** event fires, it is possible that there may still be buffered data available to read from the server. Before disconnecting from the server, the application should attempt to read any remaining data until the **Read** method returns a value of zero, or returns an error indicating that the operation would block.

See Also

[Blocking Property](#), [IsConnected Property](#), [Connect Method](#), [Disconnect Method](#), [OnConnect Event](#)

OnError Event

The **OnError** event is generated when a control error occurs.

Syntax

```
Sub object_OnError ( [Index As Integer,] ByVal ErrorCode As Variant, ByVal Description As Variant )
```

Remarks

This event occurs when an error occurs during a control action. Errors not generated by the control itself, such as errors related to the programming language or general component errors, do not trigger this event.

The ***ErrorCode*** argument specifies the last error that has occurred. If the error is network related, the error code values returned by the control correspond to those returned by the standard Windows Sockets library.

The ***Description*** argument is a string that describes the error.

See Also

[LastError Property](#), [LastErrorString Property](#), [ThrowError Property](#)

OnProgress Event

The **OnProgress** event is generated during data transfer.

Syntax

Sub *object_OnProgress* ([*Index As Integer*], **ByVal** *MessageSize As Variant*, **ByVal** *MessageCopied As Variant*, **ByVal** *Percent As Variant*)

Remarks

The **OnProgress** event is generated during the transfer of data between the client and server, indicating the amount of data exchanged. For transfers of large amounts of data, this event can be used to update a progress bar or other user-interface control to provide the user with some visual feedback. The arguments to this event are:

MessageSize

The size of the message being transferred in bytes.

MessageCopied

The number of bytes that have been transferred between the client and server.

Percent

The percentage of data that's been transferred, expressed as an integer value between 0 and 100, inclusive.

Note that this event is only generated when a message is delivered using the **SendMessage** method. If the client is writing the message data directly to the server using **Write** method then the application is responsible for calculating the completion percentage and updating any user interface controls.

See Also

[SendMessage Method](#)

OnTimeout Event

The **OnTimeout** event is fired when a blocking operation times out.

Syntax

Sub *object_OnTimeout* ([*Index As Integer*])

Remarks

The **OnTimeout** event is generated when a blocking socket operation, such as sending or receiving data, times out. To determine which operation was in progress when the timeout occurred, consult the **State** property. This event is only triggered when the **Blocking** property is set to True.

See Also

[Timeout Property](#), [OnCancel Event](#)

OnWrite Event

The **OnWrite** event is generated when data can be written to the server.

Syntax

Sub *object_OnWrite* ([*Index As Integer*])

Remarks

The **OnWrite** event is generated for non-blocking sockets when data can be written to the server after a previous attempt failed because it would cause the control to block. This event is only triggered when the **Blocking** property is set to False.

Standards	RFC 768, RFC 791, RFC 793

Overview

The SocketWrench control provides a simplified interface for the standard Windows Sockets API used to develop Internet and intranet applications using the TCP/IP protocol. With SocketWrench, you can create both client and server applications, as well as send and receive UDP datagrams. SocketWrench also supports secure connections using the standard Transport Layer Security (TLS) protocol. Enabling the security features of the control is done by setting a single property, and all of the data that is exchanged between your application and the remote host will be encrypted.

Instead of using complex API calls, virtually all network functions can be performed by setting the control's properties and responding to events. For developers who are not familiar with the details of Internet programming, SocketWrench can also insulate them from many of the common pitfalls, without sacrificing functionality or flexibility.

Each instance of the control that you use corresponds to one socket which may or may not be currently connected to a remote host. If you need access to multiple sockets, you simply create multiple instances of the control. This is most commonly needed when your application acts a server and must be able to handle several connections at one time.

Requirements

The SocketWrench control is self-registering and compatible with any programming language that supports the Component Object Model (COM) and the ActiveX control specification. If you are using Visual Basic 6.0, Service Pack 6 (SP6) is required. We recommend installing all available updates for your development tools. Although the Visual Basic 6.0 runtime is supported on Windows 11, the IDE itself is no longer officially supported by Microsoft. Legacy IDEs and compilers may also require

elevated (administrator) privileges to run properly.

The control is supported on Windows 7, Windows Server 2008 R2, and later versions of both desktop and server editions of Windows. For Windows 7, Service Pack 1 (SP1) is the minimum requirement. For Windows 8 systems, the 8.1 update must be installed. On ARM-based platforms, the minimum supported version is Windows 10 build 1709.

SocketWrench includes components for both 32-bit (x86) and 64-bit (x64) Windows platforms. All modern versions of Windows are 64-bit, but we continue to include 32-bit components for compatibility with legacy development tools such as Visual Basic 6.0. We also provide native ARM64 ActiveX controls for systems running Windows on ARM. Note that 32-bit applications on ARM run using x86 emulation, and Microsoft no longer supports native ARM32 applications.

If you are using VBScript, Visual Basic for Applications (VBA), or another scripting environment on an ARM-based system, be aware that 64-bit hosts will require ARM64 components, while 32-bit hosts will use x86 components under emulation. This includes applications created with Visual Basic 6.0. To reduce deployment complexity and avoid confusion, SocketWrench does not include ARM32 ActiveX controls in its standard redistribution packages but they are available on request for legacy or specialized scenarios.

Distribution

When you distribute an application that uses this control, you can either install the file in the same folder as your application executable or as a shared component in the appropriate system folder. If you install the control in the system folder, it is important that you distribute the correct version for the target platform and it must be registered. If you install the control in the same folder as your executable, it is recommended that you use registration-free activation or COM redirection to ensure that the correct version of the control is loaded by the application.

SocketWrench Control Properties

Property	Description
AdapterAddress	Returns the IP address associated with the specified network adapter
AdapterCount	Returns the number of available local and remote network adapters
AtMark	A read-only property that returns True if the next receive will return urgent data
AutoResolve	Determines if host names and addresses are automatically resolved
Backlog	Gets and sets the number of client connections that may be queued by a listening socket
Blocking	Gets and sets the blocking state of the control
Broadcast	Determines if datagrams should be broadcast over the network
ByteOrder	Gets and sets the byte order in which integer data will be written to and read from the socket
CertificateExpires	Return the date and time that the server certificate expires
CertificateIssued	Return the date and time that the server certificate was issued
CertificateIssuer	Returns information about the organization that issued the server certificate
CertificateName	Gets and sets the common name for the security certificate
CertificatePassword	Gets and sets the password associated with the certificate
CertificateStatus	Return the status of the server certificate
CertificateStore	Gets and sets the name of the certificate store or file
CertificateSubject	Returns information about the organization to which the server certificate was issued
CertificateUser	Gets and sets the user that owns the client certificate
CipherStrength	Return the length of the key used by the encryption algorithm
CodePage	Gets and sets the code page used when reading and writing text
ExternalAddress	Return the external IP address assigned to the local system
HashStrength	Return the length of the message digest that was selected
HostAddress	Gets and sets the IP address of the remote host
HostAlias	Returns the aliases defined for the current hostname
HostFile	Gets and sets the name of an alternate host file
HostName	Gets and sets the name of the remote host
InLine	Sets or returns if urgent data is received in-line with non-urgent data
Interval	Gets and sets the number of milliseconds between calls to the control's timer event
IsBlocked	Determine if the control is blocked performing an operation
IsClosed	Determine if the connection has been closed by the remote host
IsConnected	Determine if the control is connected to a remote host
IsInitialized	Determine if the control has been initialized
IsListening	Returns if the socket is listening for connections
IsReadable	Determine if data can be read from the socket without blocking

IsWritable	Determine if data can be written to the socket without blocking
KeepAlive	Set or return if keep-alive packets are sent on a connected socket
LastError	Gets and sets the last error that occurred on the control
LastErrorString	Return a description of the last error that occurred
Linger	Gets and sets the number of seconds to wait for the socket to close
LocalAddress	Return the IP address of the local host
LocalName	Return the name of the local host
LocalPort	Gets and sets the port number for a local listening socket
NoDelay	Enable or disable the Nagle algorithm
Options	Gets and sets the options that are used in establishing a connection
PeerAddress	Return the IP address of the remote peer
PeerName	Return the name of the remote peer
PeerPort	Return the port number of the remote connection or datagram
PhysicalAddress	Return the MAC address for the local host's Ethernet or Token Ring adapter
Protocol	Gets and sets the protocol that should be used to create the socket
RemotePort	Gets and sets the port number for a remote connection
ReservedPort	Set or return if a reserved local port number should be allocated
ReuseAddress	Set or return if an address can be reused
Secure	Set or return if a connection to the remote host is secure
SecureCipher	Return the encryption algorithm used to establish a secure connection
SecureHash	Return the message digest selected when establishing a secure connection
SecureKeyExchange	Return the key exchange algorithm used to establish a secure connection
SecureProtocol	Gets and sets the security protocol used to establish a secure connection
ThrowError	Enables or disables error handling by the application
Timeout	Gets and sets the amount of time until a blocking operation fails
Trace	Enable or disable socket function level tracing
TraceFile	Specify the socket function trace output file
TraceFlags	Gets and sets the socket function tracing flags
Urgent	Send or receive urgent data
Version	Return the current version of the control
VpnAdapter	Return the name of the active VPN adapter.
VpnAddress	Return the local IP address assigned to the active VPN adapter.

AdapterAddress Property

Returns the IP address associated with the specified network adapter.

Syntax

object.AdapterAddress(Index)

Remarks

The **AdapterAddress** property array returns the IP addresses that are associated with the local network or remote dial-up network adapters configured on the system. The **AdapterCount** property can be used to determine the number of adapters that are available.

Multihomed systems with more than one local network adapter, or a combination of local and dial-up adapters will not be listed in a specific order. An application should not make the assumption that the address returned by **AdapterAddress(0)** always refers to a local network adapter.

Note that it is possible that the **AdapterCount** property will return 0, and **AdapterAddress(0)** will return an empty string. This indicates that the system does not have a physical network adapter with an assigned IP address, and there are no dial-up networking connections currently active. If a dial-up networking connection is established at some later point, the **AdapterCount** property will change to 1, and the **AdapterAddress(0)** property will return the IP address allocated for that connection.

When using Visual Studio .NET, you must use the accessor method **get_AdapterAddress** instead of the property name, otherwise an error will be returned indicating that it not a member of the control class.

Data Type

String

See Also

[AdapterCount Property](#), [LocalAddress Property](#), [LocalName Property](#), [PhysicalAddress Property](#)

AdapterCount Property

Returns the number of available local and remote network adapters.

Syntax

object.AdapterCount

Remarks

The **AdapterCount** property returns the number of local and remote dial-up networking adapters available on the local system. This value can be used in conjunction with the **AdapterAddress** property array to enumerate the IP addresses assigned to the various network adapters.

Note that it is possible that the **AdapterCount** property will return 0, and **AdapterAddress**(0) will return an empty string. This indicates that the system does not have a physical network adapter with an assigned IP address, and there are no dial-up networking connections currently active. If a dial-up networking connection is established at some later point, the **AdapterCount** property will change to 1, and the **AdapterAddress**(0) property will return IP address allocated for that connection.

Data Type

Integer (Int32)

See Also

[AdapterAddress Property](#), [LocalAddress Property](#), [LocalName Property](#)

AtMark Property

A read-only property that returns True if the next receive will return urgent data.

Syntax

object.AtMark

Remarks

This property can only be used if the Protocol is swProtocolTcp and the InLine property has been set to True. Reading this property is the same as using the SIOCATMARK option with the **ioctlsocket** function.

Data Type

Boolean

See Also

[Urgent Property](#), [OnRead Event](#)

AutoResolve Property

Determines if host names and addresses are automatically resolved.

Syntax

object.AutoResolve [= { True | False }]

Remarks

Setting the **AutoResolve** property determines if the control automatically resolves host names and addresses specified by the **HostName** and **HostAddress** properties. If set to True, setting the **HostName** property will cause the control to automatically determine the corresponding IP address and set the **HostAddress** property accordingly. Likewise, setting the **HostAddress** property will cause the control to determine the host name and set the **HostName** property. Setting the property to False prevents the control from resolving host names until a connection attempt is made.

Note: When using the domain name service (DNS), setting the **HostName** or **HostAddress** property may cause the thread to block, sometimes for several seconds, until the name or address is resolved. To prevent this behavior, set **AutoResolve** to False.

Data Type

Boolean

See Also

[HostAddress Property](#), [HostFile Property](#), [HostName Property](#), [Resolve Method](#)

Backlog Property

Gets and sets the number of client connections that may be queued by a listening socket.

Syntax

object.Backlog [= *backlog*]

Remarks

The **Backlog** property specifies the maximum size of the queue used to manage pending connections to the server. If the property is set to value which exceeds the maximum size for the underlying service provider, it will be silently adjusted to the nearest legal value. There is no standard way to determine what the maximum backlog value is.

This property must be set to the desired value before the **Listen** method is called, if the **Listen** method is used with default parameters. The default backlog value is 5 on all Windows platforms. The Windows Server platforms support a maximum backlog value of 200.

Note that this property does not specify the total number of connections that the server application may accept. It only specifies the size of the backlog queue which is used to manage pending client connections. Once the client connection has been accepted, it is removed from the queue.

Data Type

Integer (Int32)

See Also

[IsListening Property](#), [OnAccept Event](#), [Accept Method](#), [Listen Method](#)

Blocking Property

Gets and sets the blocking state of the control.

Syntax

object.**Blocking** [= { True | False }]

Remarks

Setting the **Blocking** property determines if control actions complete synchronously or asynchronously. If set to True, then each control action (such as sending or receiving data) will return when the operation has completed or timed-out. If set to False, control actions will return immediately. If the operation would result in the control blocking (such as attempting to receive data when none has been written), an error is generated. Control events such as **OnDisconnect**, **OnRead** and **OnWrite** are only fired if the socket is non-blocking.

Data Type

Boolean

See Also

[IsBlocked Property](#)

Broadcast Property

Determines if datagrams should be broadcast over the network.

Syntax

object.**Broadcast** [= { True | False }]

Remarks

If the **Broadcast** property is set to a value of true, the datagram written to the socket will be broadcast to all systems on the network. Use of this property is restricted to the swProtocolUdp protocol.

Data Type

Boolean

See Also

[InLine Property](#), [KeepAlive Property](#), [ReuseAddress Property](#), [Route Property](#), [Protocol Property](#)

ByteOrder Property

Gets and sets the byte order in which integer data will be written to and read from the socket.

Syntax

object.ByteOrder [= 0 | 1]

Remarks

The **ByteOrder** property is used to specify how 16-bit (short) integer and 32-bit (long) integer data is written to and read from the socket. The default value for this property is 0, which specifies that integers should be written in the native byte order for the local machine. A value of 1 indicates that integers should be written in network byte order.

When applications write integer values on a socket (instead of string representations of those values), they should typically be converted to network byte order before they are sent. Likewise, when an integer value is read, it should then be converted from the network byte order back to the byte order used by the local machine. The native byte order, also called the host byte order, should only be used if it can be assured that both the sender and the receiver are running on an identical or compatible machine architectures (for example, if both systems are Intel-based).

This property will affect how data is read by the **Read** method and by the **Write** method, if the Variant data that is being read or written is recognized as integer data.

Data Type

Integer (Int32)

CertificateExpires Property

Return the date and time that the server certificate expires.

Syntax

object.CertificateExpires

Remarks

The **CertificateExpires** property returns the date and time that the server certificate expires. This property will return an empty string if a secure connection has not been established with the server.

Data Type

String

See Also

[CertificateIssued Property](#), [CertificateIssuer Property](#), [CertificateStatus Property](#), [CertificateSubject Property](#), [Secure Property](#)

CertificateIssued Property

Return the date and time that the server certificate was issued.

Syntax

object.CertificateIssued

Remarks

The **CertificateIssued** property returns the date and time that the server certificate was issued. This property will return an empty string if a secure connection has not been established with the server.

Data Type

String

See Also

[CertificateExpires Property](#), [CertificateIssuer Property](#), [CertificateStatus Property](#), [CertificateSubject Property](#), [Secure Property](#)

CertificateIssuer Property

Returns information about the organization that issued the server certificate.

Syntax

object.CertificateIssuer

Remarks

The **CertificateIssuer** property returns a string that contains information about the organization that issued the server certificate. The string value is a comma separated list of tagged name and value pairs. In the nomenclature of the X.500 standard, each of these pairs are called a relative distinguished name (RDN), and when concatenated together, forms the issuer's distinguished name (DN). For example:

C=US, O="RSA Data Security, Inc.", OU=Secure Server Certification Authority

To obtain a specific value, such as the name of the issuer or the issuer's country, the application must parse the string returned by this property. Some of the common tokens used in the distinguished name are:

Name	Description
C	The ISO standard two character country code
S	The name of the state or province
L	The name of the city or locality
O	The name of the company or organization
OU	The name of the department or organizational unit
CN	The common name; with X.509 certificates, this is the domain name of the site the certificate was issued for

This property will return an empty string if a secure connection has not been established with the server.

Data Type

String

Example

The following example demonstrates how to extract the value of a relative distinguished name token:

```
Function GetCertNameValue(ByVal strValue As String, ByVal strFieldName As String)
As String
    Dim strFieldValue As String
    Dim cchValue As Integer, cchFieldName As Integer
    Dim nOffset As Integer

    GetCertNameValue = ""
    cchValue = Len(strValue)
    cchFieldName = Len(strFieldName)

    If cchValue = 0 Or cchFieldName = 0 Then
        Exit Function
    End If
```

```

nOffset = InStr(strValue, strFieldName & "=")

If nOffset > 0 Then
    '
    ' If the field name was found in the string, then
    ' remove everything to the left of the token from
    ' the string
    '
    strFieldValue = Right(strValue, cchValue - (nOffset + cchFieldName))

    '
    ' If the value is quoted, then strip off the leading
    ' quote and look for the ending quote in the string;
    ' otherwise look for the comma that marks the end of
    ' the field name/value pair
    '
    If Left(strFieldValue, 1) = Chr(34) Then
        strFieldValue = Right(strFieldValue, Len(strFieldValue) - 1)
        nOffset = InStr(strFieldValue, Chr(34))
    Else
        nOffset = InStr(strFieldValue, ",")
    End If

    '
    ' If the offset is 0, then the name/value pair is
    ' the last token in the string; otherwise, remove
    ' everything to the right of that position
    '
    If nOffset > 0 Then
        strFieldValue = Left(strFieldValue, nOffset - 1)
    End If

    GetCertNameValue = strFieldValue
End If

```

End Function

This function could then be used to return the name of the company who issued the server certificate:

```

Dim strIssuer As String
Dim strCompanyName As String

strIssuer = HttpClient1.CertificateIssuer
If Len(strIssuer) = 0 Then
    MsgBox "A secure connection has not been established"
Else
    strCompanyName = GetCertNameValue(strIssuer, "O")
    MsgBox "This certificate was issued by " & strCompanyName
End If

```

See Also

[CertificateExpires Property](#), [CertificateIssued Property](#), [CertificateStatus Property](#), [CertificateSubject Property](#), [Secure Property](#)

CertificateName Property

Gets and sets the common name for the security certificate.

Syntax

object.CertificateName [= *name*]

Remarks

This property sets the common name or friendly name of the client certificate that should be used to establish the connection with the server, or the name of the server certificate if the control is being used to create a server application. This property is used in conjunction with the **CertificateStore** property to identify the certificate that should be used to create a security context for the session.

For client applications, it is only required that you set this property value if the server requires a client certificate for authentication. If this property is not set, a client certificate will not be provided to the server. The certificate must be designated as a client certificate and have a private key associated with it, otherwise the connection attempt will fail.

For server applications, it is required that you specify a certificate name if security has been enabled by setting the **Secure** property to True. The certificate must be designated as a server certificate and have a private key associated with it, otherwise the control will be unable to accept incoming client connections.

Certificates may be installed and viewed on the local system using the Certificate Manager that is included with the Windows operating system. For more information, refer to the documentation for the Microsoft Management Console.

Data Type

String

See Also

[CertificateStore Property](#), [Secure Property](#)

CertificatePassword Property

Gets and sets the password associated with the certificate.

Syntax

object.CertificatePassword [= *password*]

Remarks

This property sets the password that should be used to access a certificate in the specified certificate store. It is only required when the **CertificateStore** property specifies a file that contains a certificate and private key in PKCS #12 format.

Data Type

String

See Also

[CertificateName Property](#), [CertificateStore Property](#), [Secure Property](#)

CertificateStatus Property

Return the status of the server certificate.

Syntax

object.CertificateStatus

Remarks

The **CertificateStatus** property returns an integer value which identifies the status of the server certificate. This property may return one of the following values:

Value	Description
swCertificateNone	No certificate information is available. A secure connection was not established with the server.
swCertificateValid	The certificate is valid.
swCertificateNoMatch	The certificate is valid, however the domain name specified in the certificate does not match the domain name of the site that the client has connected to. This is typically the case if the HostAddress property is used rather than the HostName property. It is recommended that the client examine the CertificateSubject property to determine the domain name of the site that the certificate was issued for.
swCertificateExpired	The certificate has expired and is no longer valid. The client can examine the CertificateExpires property to determine when the certificate expired.
swCertificateRevoked	The certificate has been revoked and is no longer valid. It is recommended that the client application immediately terminate the connection if this status is returned.
swCertificateUntrusted	The certificate has not been issued by a trusted authority, or the certificate is not trusted on the local host. It is recommended that the client application immediately terminate the connection if this status is returned.
swCertificateInvalid	The certificate is invalid. This typically indicates that the internal structure of the certificate is damaged. It is recommended that the client application immediately terminate the connection if this status is returned.

This property value should be checked after the connection to the server has completed, but prior to beginning a transaction. If a secure connection has not been established, this property will return a value of zero.

Data Type

Integer (Int32)

Example

The following example establishes a secure connection to a server:

```
SocketWrench1.HostName = strHostName  
SocketWrench1.Secure = True
```

```
nError = SocketWrench1.Connect()  
If nError > 0 Then
```

```
        MsgBox "Unable to connect to server " & strHostName, vbExclamation
    Exit Sub
End If

If SocketWrench1.CertificateStatus <> swCertificateValid Then
    nResult = MsgBox("The server certificate could not be validated" & vbCrLf & _
        "Are you sure you wish to continue?", vbYesNo)

    If nResult = vbNo Then
        SocketWrench1.Disconnect
        Exit Sub
    End If
End If

SocketWrench1.Disconnect
```

See Also

[CertificateExpires Property](#), [CertificateIssued Property](#), [CertificateIssuer Property](#), [CertificateSubject Property](#), [Secure Property](#)

CertificateStore Property

Gets and sets the name of the certificate store or file.

Syntax

object.CertificateStore [= *store*]

Remarks

This property sets the name of the certificate store that contains the certificate that should be used when establishing a secure connection with the server or accepting secure client connections. The certificate may either be stored in the registry or in a file. If the certificate is stored in the registry, then this property should be set to one of the following predefined values:

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. If a certificate store is not specified, this is the default value that is used.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

In most cases the certificate will be installed in the user's personal certificate store, and therefore it is not necessary to set this property value because that is the default location that will be used to search for the certificate. This property is only used if the **CertificateName** property is also set to a valid certificate name.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU" for the current user, or "HKLM" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, it will default to the certificate store for the current user.

This property may also be used to specify a file that contains the certificate. In this case, the property should specify the full path to the file and must contain both the certificate and private key in PKCS #12 format. If the file is protected by a password, the **CertificatePassword** property must also be set to specify the password.

Data Type

String

See Also

[CertificateName Property](#), [CertificatePassword Property](#), [Secure Property](#)

CertificateSubject Property

Returns information about the organization that the server certificate was issued to.

Syntax

`object.CertificateSubject`

Remarks

The **CertificateSubject** property returns a string that contains information about the organization that the server certificate was issued for. The string value is a comma separated list of tagged name and value pairs. In the nomenclature of the X.500 standard, each of these pairs are called a relative distinguished name (RDN), and when concatenated together, forms the subject's distinguished name (DN). For example:

`C=US, O="RSA Data Security, Inc.", OU=Secure Server Certification Authority`

To obtain a specific value, such as the name of the subject's company or country, the application must parse the string returned by this property. Some of the common tokens used in the distinguished name are:

Name	Description
C	The ISO standard two character country code
S	The name of the state or province
L	The name of the city or locality
O	The name of the company or organization
OU	The name of the department or organizational unit
CN	The common name; with X.509 certificates, this is the domain name of the site the certificate was issued for

This property will return an empty string if a secure connection has not been established with the server.

Data Type

String

Example

The following example demonstrates how to extract the value of a relative distinguished name token:

```
Function GetCertNameValue(ByVal strValue As String, ByVal strFieldName As String)
As String
    Dim strFieldValue As String
    Dim cchValue As Integer, cchFieldName As Integer
    Dim nOffset As Integer

    GetCertNameValue = ""
    cchValue = Len(strValue)
    cchFieldName = Len(strFieldName)

    If cchValue = 0 Or cchFieldName = 0 Then
        Exit Function
    End If
```

```

nOffset = InStr(strValue, strFieldName & "=")

If nOffset > 0 Then
    '
    ' If the field name was found in the string, then
    ' remove everything to the left of the token from
    ' the string
    '
    strFieldValue = Right(strValue, cchValue - (nOffset + cchFieldName))

    '
    ' If the value is quoted, then strip off the leading
    ' quote and look for the ending quote in the string;
    ' otherwise look for the comma that marks the end of
    ' the field name/value pair
    '
    If Left(strFieldValue, 1) = Chr(34) Then
        strFieldValue = Right(strFieldValue, Len(strFieldValue) - 1)
        nOffset = InStr(strFieldValue, Chr(34))
    Else
        nOffset = InStr(strFieldValue, ",")
    End If

    '
    ' If the offset is 0, then the name/value pair is
    ' the last token in the string; otherwise, remove
    ' everything to the right of that position
    '
    If nOffset > 0 Then
        strFieldValue = Left(strFieldValue, nOffset - 1)
    End If

    GetCertNameValue = strFieldValue
End If

```

End Function

This function could then be used to return the domain name that the server certificate was issued for:

```

Dim strSubject As String
Dim strDomainName As String

strSubject = HttpClient1.CertificateSubject
If Len(strSubject) = 0 Then
    MsgBox "A secure connection has not been established"
Else
    strDomainName = GetCertNameValue(strSubject, "CN")
    MsgBox "This certificate was issued for " & strDomainName
End If

```

See Also

[CertificateExpires Property](#), [CertificateIssued Property](#), [CertificateIssuer Property](#), [CertificateStatus Property](#), [Secure Property](#)

CertificateUser Property

Gets and sets the user that owns the certificate.

Syntax

object.CertificateUser [= *username*]

Remarks

This property sets the name of the user that owns the certificate that will be used to establish a secure connection with the server or accept secure client connections. If this property is not set, the certificate store for the current user will be used when searching for the certificate. If this property is used to specify another user, the process must have the appropriate permission to access the registry location that contains the client certificate. On Windows Vista and later versions of the operating system, this requires that the process run with elevated privileges.

Data Type

String

See Also

[CertificateName Property](#), [CertificateStore Property](#), [Secure Property](#)

CipherStrength Property

Return the length of the key used by the encryption algorithm.

Syntax

object.CipherStrength

Remarks

The **CipherStrength** property returns the number of bits in the key used to encrypt the secure data stream. Common values returned by this property are 128 and 256. A key length of 40-bits or 56-bits is considered to be insecure, and subject to brute force attacks. 128-bit and 256-bit keys are considered secure. If this property returns a value of 0, this means that a secure connection has not been established with the server.

Data Type

Integer (Int32)

See Also

[HashStrength Property](#), [Secure Property](#), [SecureCipher Property](#), [SecureHash Property](#), [SecureKeyExchange Property](#), [SecureProtocol Property](#)

CodePage Property

Gets and sets the code page used when reading and writing text.

Syntax

object.CodePage [= *value*]

Remarks

The **CodePage** property is an integer value which specifies how strings are encoded when data is sent or received. Any valid code page identifier may be specified. Some common values are:

Value	Description
0	Text sent and received using a string should be converted using the ANSI code page for the current locale.
1	Text sent and received using a string should be converted using the system default OEM code page. The OEM code page typically contains characters that are used by console applications and are based on character sets commonly used by MS-DOS. You should not use this code page unless you know the server is sending text which includes OEM characters.
1252	Text sent and received using a string should be converted using the Windows ANSI code page for western European languages. This code page is commonly used by legacy Windows applications for English and some other western languages. It should be noted that while this code page is similar to ISO 8859-1 character encoding, it is not identical.
28591	Text sent and received using a string should be converted using the ISO 8859-1 code page for western European languages. This code page is commonly referred to as Latin-1 and is similar to the Windows 1252 code page.
65000	Data that is sent and received using a string should be converted using UTF-7 encoding. If this code page is specified, data written to the socket will be encoded as UTF-7 encoded Unicode. All data received from the server will be converted from UTF-7. It is not recommended that you use this code page unless you know that the remote host is sending UTF-7 encoded text.
65001	Data that is sent and received using a string should be converted using UTF-8 encoding. If this code page is specified, data written to the socket will be encoded as UTF-8 encoded Unicode. All data received from the server will be converted from UTF-8 to UTF-16 Unicode. Because UTF-8 is backwards compatible with the ASCII character set, it is safe to use this encoding option when sending and receiving ASCII text.

A complete list of available [code page identifiers](#) can be found in Microsoft's documentation for the Win32 API.

All data which is exchanged over a socket is sent and received as 8-bit bytes, typically referred to as "octets" in networking terminology. However, the internal string type used by ActiveX controls are Unicode where each character is represented by 16 bits. To send and receive data using strings, these Unicode strings are converted to a stream of bytes.

By default, strings are converted to an array of bytes using the code page for the current locale, mapping the 16-bit Unicode characters to bytes. Similarly, when reading data from the socket into a

string buffer, the stream of bytes received from the remote host are converted to Unicode before they are returned to your application.

If you are exchanging text with another system and it appears to be corrupted or characters are being replaced with question marks or other symbols, it is likely the system is sending text which is using a different character encoding. Most services use UTF-8 encoding to represent non-ASCII characters and selecting the UTF-8 code page will typically resolve the issue.

Strings are only guaranteed to be safe when sending and receiving text. Using a string data type is not recommended when reading or writing binary data to a socket. If possible, you should always use a byte array as the buffer parameter for the **Read** and **Write** methods whenever you are exchanging binary data.

For backwards compatibility, the control defaults to using the code page for the current locale. This property value directly corresponds to Windows code page identifiers, and will accept any valid code page in addition to the values listed above. Setting this property to an invalid code page will result in an error.

Data Type

Integer (Int32)

See Also

[Read Method](#), [ReadLine Method](#), [ReadStream Method](#), [Write Method](#), [WriteLine Method](#), [WriteStream Method](#)

ExternalAddress Property

Return the external IP address for the local system.

Syntax

object.ExternalAddress

Remarks

The **ExternalAddress** property returns the IP address assigned to the router that connects the local host to the Internet. This is typically used by an application executing on a system in a local network that uses a router which performs Network Address Translation (NAT). In that network configuration, the **LocalAddress** property will only return the IP address for the local system on the LAN side of the network unless a connection has already been established to a remote host.

This property can be used to determine the IP address assigned to the router on the Internet side of the connection and can be particularly useful for servers running on a system behind a NAT router. Note that you should not assign the **LocalAddress** property to the value returned by the **ExternalAddress** property. If the server is running behind a NAT router, the router must be configured to forward incoming connections to the appropriate address on the local network.

It may not be possible to determine the external IP address for the local system for a number of reasons, particularly if it is behind a firewall or uses a proxy server that restricts access to external sites on the Internet. If you are using a VPN (Virtual Private Network), this property will return the external IP address for the VPN adapter and not your local network connection. The **VpnAdapter** property can be used to obtain the name of the active VPN adapter and the **VpnAddress** property can be used to determine the IP address assigned to the adapter.

Checking this property value may cause the current thread to block until the external IP address can be resolved and should never be used in conjunction with asynchronous socket connections.

Data Type

String

See Also

[HostAddress Property](#), [LocalAddress Property](#), [PeerAddress Property](#), [VpnAdapter Property](#), [VpnAddress Property](#)

Handle Property

Returns the descriptor for the current socket.

Syntax

object.**Handle**

Remarks

The **Handle** read-only property returns the descriptor of the socket being used by the control. If the control is not connected to a remote host, a value of -1 is returned. This property can be used in conjunction with direct calls to the Windows Sockets API.

When using Visual Studio .NET, you must use the property name **CtlHandle** instead.

Data Type

Integer (Int32)

See Also

[Connect Method](#), [Listen Method](#)

HashStrength Property

Return the length of the message digest that was selected.

Syntax

object.HashStrength

Remarks

The **HashStrength** property returns the number of bits used in the message digest (hash) that was selected. Common values returned by this property are 128 and 160. If this property returns a value of 0, this means that a secure connection has not been established with the server.

Data Type

Integer (Int32)

See Also

[CipherStrength Property](#), [Secure Property](#), [SecureCipher Property](#), [SecureHash Property](#), [SecureKeyExchange Property](#), [SecureProtocol Property](#)

HostAddress Property

Gets and sets the IP address of the remote host.

Syntax

object.HostAddress [= *ipaddress*]

Remarks

The **HostAddress** property can be used to set the IP address for a remote system that you wish to communicate with. If the address is valid and matches an entry in the host table, the **HostName** property will be changed to match the address.

Data Type

String

See Also

[AutoResolve Property](#), [HostFile Property](#), [HostName Property](#), [LocalAddress Property](#), [Resolve Method](#)

HostAlias Property

Returns the aliases defined for the current hostname.

Syntax

object.HostAlias(*Index*)

Remarks

The **HostAlias** property array returns the aliases assigned to the host specified by the **HostAddress** or **HostName** properties. If the host address or name can be resolved, the first element in the **HostAlias** array (an index value of 0) always refers to the host's fully qualified domain name. The end of the alias list is indicated when the property returns an empty string.

When using Visual Studio .NET, you must use the accessor method **get_HostAlias** instead of the property name, otherwise an error will be returned indicating that it not a member of the control class.

Data Type

String

Example

The following example places the all of the aliases for a specific host into a listbox:

```
Dim nIndex As Integer

List1.Clear
Socket1.HostName = Trim(Text1.Text)

Do While Len(Socket1.HostAlias(nIndex)) > 0
    List1.AddItem Socket1.HostAlias(nIndex)
    nIndex = nIndex + 1
Loop
```

See Also

[HostAddress Property](#), [HostName Property](#)

HostFile Property

Gets and sets the name of an alternate host file.

Syntax

object.HostFile [= *filename*]

Remarks

The **HostFile** property is used to specify the name of an alternate file for resolving hostnames and IP addresses. The host file is used as a database that maps an IP address to one or more hostnames, and is used when setting the **HostName** or **HostAddress** properties and establishing a connection with a remote host. The file is a plain text file, with each line in the file specifying a record, and each field separated by spaces or tabs. The format of the file must be as follows:

ipaddress hostname [hostalias ...]

For example, one typical entry maps the name "localhost" to the local loopback IP address. This would be entered as:

127.0.0.1 localhost

The hash character (#) may be used to specify a comment in the file, and all characters after it are ignored up to the end of the line. Blank lines are ignored, as are any lines which do not follow the required format.

Setting this property loads the file into memory allocated for the current thread. If the contents of the file have changed after the function has been called, those changes will not be reflected when resolving hostnames or addresses. To reload the host file from disk, set the property again with the same file name. To remove the alternate host file from memory, specify an empty string as the file name.

If a host file has been specified, it is processed before the default host file when resolving a hostname into an IP address, or an IP address into a hostname. If the host name or address is not found, or no host file has been specified, a nameserver lookup is performed.

Because the alternate host file is cached for the current thread, setting this property will affect all instances of the control in the same thread. For example, if a project has three instances of the control loaded on a form, setting the **HostFile** property will affect all three controls, not just the control that set the property. To determine if an alternate host file has been cached, check the property value. If the property returns an empty string, no alternate host file has been cached.

Data Type

String

See Also

[AutoResolve Property](#), [HostAddress Property](#), [HostName Property](#), [LocalName Property](#), [Resolve Method](#)

HostName Property

Gets and sets the name of the remote host.

Syntax

object.HostName [= *hostname*]

Remarks

The **HostName** property should be set to the name of the remote system that you wish to communicate with. If the name is found in the host table, the **HostAddress** property is updated to reflect the IP address of the host.

Note that it is legal to assign an IP address to this property, but it is not legal to assign a host name to the **HostAddress** property.

Data Type

String

See Also

[AutoResolve Property](#), [HostAddress Property](#), [HostFile Property](#), [LocalName Property](#), [Resolve Method](#)

InLine Property

Sets or returns if urgent data is received in-line with non-urgent data.

Syntax

object.InLine [= { True | False }]

Remarks

The **InLine** property controls how urgent (out-of-band) data is handled when reading data from the socket. If set to a value of true, urgent data is placed in the data stream along with non-urgent data. To determine if the data that is being read is urgent, the **AtMark** property can be read.

Urgent data is sent and received directly from the socket, and is not buffered even if buffering is enabled. It is recommended that you do not enable buffering if urgent data is being received in-line.

Data Type

Boolean

See Also

[NoDelay Property](#), [Urgent Property](#), [OnRead Event](#)

Interval Property

Gets and sets the number of milliseconds between calls to the control's **OnTimer** event.

Syntax

object.Interval [= *milliseconds*]

Remarks

The **Interval** property specifies the number of milliseconds between calls to the **OnTimer** event. A value of zero indicates that the timer is disabled and no events will be generated. The maximum interval value is 65536 milliseconds, which is slightly more than one minute.

Data Type

Integer (Int32)

See Also

[OnTimer Event](#)

IsBlocked Property

Return if the control is blocked performing an operation.

Syntax

object.IsBlocked

Remarks

The **IsBlocked** property returns True if the specified control is blocked performing an operation. Because the Windows Sockets API only permits one blocking operation per thread of execution, this property should be checked before starting any blocking operation.

If the **IsBlocked** property returns False, this means there are no blocking operations on the current thread at that time. If the property returns True, this tells you that you can't proceed with a socket operation. However, if the property returns False this does not guarantee that the next socket operation will not fail with a **swErrorOperationWouldBlock** or **swErrorOperationInProgress** error. The application should treat these errors as recoverable, and should be prepared to retry operations that result in them.

Note that this property will return True if there is *any* blocking operation being performed by the application, regardless of whether the control is responsible for the blocking operation or not.

Data Type

Boolean

See Also

[Blocking Property](#), [LastError Property](#)

IsClosed Property

Determine if the connection has been closed by the remote host.

Syntax

object.IsClosed

Remarks

The **IsClosed** property returns True if the socket connection has been closed by the remote host. Note that it is possible to continue to receive data due to buffering.

Data Type

Boolean

See Also

[IsReadable Property](#), [IsWritable Property](#)

IsConnected Property

Determine if the control is connected to a remote host.

Syntax

object.IsConnected

Remarks

The **IsConnected** read-only property is set to a value of True if the control is connected with a remote host, otherwise the property has a value of false.

Data Type

Boolean

See Also

[Connect Method](#), [Disconnect Method](#), [OnConnect Event](#)

IsInitialized Property

Determine if the control has been initialized.

Syntax

object.IsInitialized

Remarks

The **IsInitialized** property is used to determine if the current instance of the control has been initialized properly. Normally this is done automatically when the control is loaded, however there are circumstances where the control may not be able to initialize itself. If this property returns **False**, the application must call the **Initialize** method to initialize the control before performing any other operation.

The most common reason that the control may not initialize correctly is that no valid development or runtime license key can be found or the license key that was provided is invalid. It may also indicate a problem with the system configuration or user access rights, such as not being able to load the required networking libraries or not being able to access the system registry.

Data Type

Boolean

See Also

[Initialize Method](#)

IsListening Property

Returns if the socket is listening for connections.

Syntax

object.IsListening

Remarks

The **IsListening** property returns True if the socket is listening for connections after the **Listen** method is called.

Data Type

Boolean

See Also

[Backlog Property](#), [Listen Method](#), [OnAccept Event](#)

IsReadable Property

Determine if data can be read from the socket without blocking.

Syntax

object.IsReadable

Remarks

The **IsReadable** property returns True if data can be read from the socket without blocking. For non-blocking sockets, this property can be checked before the application attempts to read the socket, preventing an error.

Data Type

Boolean

See Also

[IsClosed Property](#), [IsWritable Property](#), [Peek Method](#), [Read Method](#), [OnRead Event](#)

IsWritable Property

Determine if data can be written to the socket without blocking.

Syntax

object.IsWritable

Remarks

The **IsWritable** property returns True if data can be written to the socket without blocking. For non-blocking sockets, this property can be checked before the application attempts to write to the socket, preventing an error.

If the **IsWritable** property returns False, this means that the application cannot write to the socket at that time. However, if the property returns True, this does not guarantee that you will be able to write to the socket without an error. The next socket operation may result in a **swErrorOperationWouldBlock** or **swErrorOperationInProgress** error. The application should treat these errors as recoverable, and should be prepared to retry operations that result in them.

Data Type

Boolean

See Also

[IsClosed Property](#), [IsReadable Property](#), [OnWrite Event](#)

KeepAlive Property

Set or return if keep-alive packets are sent on a connected socket.

Syntax

object.KeepAlive [= { True | False }]

Remarks

Setting the **KeepAlive** property to a value of true indicates that packets are to be sent to the remote system when no data is being exchanged to keep the connection active. This property can only be set for stream sockets that were created with the **Protocol** property set to a value of **swProtocolTcp**.

If this property is set to true, keep-alive packets will start being generated five seconds after the socket has become idle with no data being sent or received. Enabling this option can be used by applications to detect when a physical network connection has been lost. However, it is recommended that most applications query the remote host directly to determine if the connection is still active. This is typically accomplished by sending specific commands to the server to query its status, or checking the elapsed time since the last response from the server.

Data Type

Boolean

See Also

[Broadcast Property](#), [InLine Property](#), [NoDelay Property](#), [Protocol Property](#), [ReuseAddress Property](#), [Route Property](#)

LastError Property

Gets and sets the last error that occurred on the control.

Syntax

object.LastError [= *errorcode*]

Remarks

The **LastError** property can be read to determine the last error that occurred for this control. If a value is assigned to this property, it must either be zero (to clear the error) or a valid error code for the control.

Data Type

Integer (Int32)

See Also

[LastErrorString Property](#), [ThrowError Property](#), [OnError Event](#)

LastErrorString Property

Return a description of the last error that occurred.

Syntax

object.LastErrorString

Remarks

The **LastErrorString** property returns a string that contains a description of the last error that occurred.

Data Type

String

See Also

[LastError Property](#), [ThrowError Property](#), [OnError Event](#)

Linger Property

Gets and sets the number of seconds to wait for the socket to close.

Syntax

object.Linger [= *seconds*]

Remarks

Setting the **Linger** property to a value greater than zero indicates that the **Disconnect** method should wait up to the specified number of seconds for any data on the socket to be written before it is closed. A value of zero indicates that the socket should be closed immediately (but gracefully, without data loss).

Data Type

Integer (Int32)

See Also

[OnDisconnect Event](#)

LocalAddress Property

Return the IP address of the local host.

Syntax

object.LocalAddress

Remarks

The **LocalAddress** read-only property returns the local host's IP address in dot notation, as four numbers separated by periods.

Data Type

String

See Also

[AutoResolve Property](#), [ExternalAddress Property](#), [HostAddress Property](#), [LocalName Property](#), [Bind Method](#)

LocalName Property

Return the name of the local host.

Syntax

object.LocalName

Remarks

The **LocalName** read-only property returns the fully qualified domain name of the local system. This consists of the local computer name and its domain name. The actual value returned depends on the system configuration. If no domain has been specified for the system, then only the machine name will be returned.

Data Type

String

See Also

[AutoResolve Property](#), [HostName Property](#), [LocalAddress Property](#), [Resolve Method](#)

LocalPort Property

Gets and sets the port number for a local listening socket.

Syntax

object.LocalPort [= *port*]

Remarks

The **LocalPort** property is used to set the port number that a server will listen on for connections.

Data Type

Integer (Int32)

See Also

[PeerPort Property](#), [RemotePort Property](#), [ReservedPort Property](#), [Bind Method](#), [Listen Method](#)

NoDelay Property

Enable or disable the Nagle algorithm.

Syntax

object.NoDelay [= { True | **False** }]

Remarks

The **NoDelay** property is used to enable or disable the Nagle algorithm, which buffers unacknowledged data and ensures that a full-size packet can be sent to the remote host. By default this property value is set to False, which enables the Nagle algorithm (in other words, the data being written may not actually be sent until it is optimal to do so). Setting this property to True disables the Nagle algorithm, minimizing the time delays between the data packets being sent.

This property should be set to True only if it is absolutely required and the implications of doing so are understood. Disabling the Nagle algorithm can have a significant negative impact on the performance of the application.

Data Type

Boolean

See Also

[InLine Property](#), [KeepAlive Property](#), [ReuseAddress Property](#), [Route Property](#)

Options Property

Gets and sets the options that are used in establishing a connection.

Syntax

object.Options [= *value*]

Remarks

The **Options** property is an integer value which specifies one or more options. The value specified for this property will be used as the default options when connecting to the server. The property value is created by using a bitwise operator with one or more of the following values:

Value	Description
swOptionBroadcast	This option specifies that broadcasting should be enabled for datagrams. This option is invalid for stream sockets.
swOptionDontRoute	This option specifies default routing should not be used. This option should not be specified unless absolutely necessary.
swOptionKeepAlive	This option specifies that packets are to be sent to the remote system when no data is being exchanged to keep the connection active. This is only valid for stream sockets.
swOptionNoDelay	This option disables the Nagle algorithm. By default, small amounts of data written to the socket are buffered, increasing efficiency and reducing network congestion. However, this buffering can negatively impact the responsiveness of certain applications. This option disables this buffering and immediately sends data packets as they are written to the socket.
swOptionInLine	This option specifies that out-of-band data should be received inline with the standard data stream. This option is only valid for stream sockets.
swOptionTrustedSite	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the TLS protocol.
swOptionSecure	This option specifies that a secure connection should be established with the remote host. The specific version of TLS can be specified by setting the SecureProtocol property. By default, the connection will use TLS 1.2 and the strongest cipher suites available. Older versions of Windows prior to Windows 7 and Windows Server 2008 R2 only support TLS 1.0 and secure connections will automatically downgrade on those platforms.
swOptionSecureFallback	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
swOptionPreferIPv6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4

	address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.

Several of these options correspond to boolean properties which can be used to enable or disable specific functionality. For example, setting the **Secure** to True is the same as specifying the **swOptionSecure** option. We generally recommend setting individual properties when they are available, or explicitly specifying the required options when calling the **Connect** method.

Data Type

Integer (Int32)

See Also

[Broadcast Property](#), [InLine Property](#), [NoDelay Property](#), [Secure Property](#), [SecureProtocol Property](#), [Connect Method](#)

PeerAddress Property

Return the IP address of the remote peer.

Syntax

object.PeerAddress

Remarks

The **PeerAddress** property returns the IP address of the remote system that the local host is connected to. If a datagram socket is being used, this property will return the address of the system which sent the last datagram that was read. If no connection has been established, this property will return 255.255.255.255.

If this property is read inside an **OnAccept** event handler, it will return the IP address of the client that is requesting the connection. The application may use this information to determine if it wishes to accept or reject the client connection. If the IP address information is not available for the client at that time, this property will return the address 0.0.0.0.

Data Type

String

See Also

[HostAddress Property](#), [LocalAddress Property](#), [PeerName Property](#), [PeerPort Property](#)

PeerName Property

Return the name of the remote peer.

Syntax

object.PeerName

Remarks

The **PeerName** property returns the name of the remote system that the local host is connected to. If a datagram socket is being used, this property will return the name of the system which sent the last datagram that was read.

Accessing this property causes the control to perform a blocking reverse DNS lookup, attempting to match the client Internet address with a hostname. Not all addresses have a reverse DNS record, in which case this property will return an empty string. It is recommended that most applications use the value of the **PeerAddress** property rather than use the **PeerName** property to distinguish between connections from a remote host.

Data Type

String

See Also

[HostName Property](#), [LocalName Property](#), [PeerAddress Property](#), [PeerPort Property](#)

PeerPort Property

Return the port number of the remote connection or datagram.

Syntax

object.**PeerPort**

Remarks

The **PeerPort** property returns the port number that the remote host has used when establishing a connection with the local system. If a datagram socket is being used, this property will return the port number used by the remote host which sent the last datagram that was received.

Data Type

String

See Also

[LocalPort Property](#), [PeerAddress Property](#), [PeerName Property](#), [RemotePort Property](#)

PhysicalAddress Property

Return the MAC address for the local host's Ethernet or Token Ring adapter.

Syntax

object.PhysicalAddress

Remarks

The **PhysicalAddress** property returns the Media Access Control (MAC) address for an Ethernet or Token Ring network adapter installed and configured on the local system. Since it is guaranteed that every adapter is assigned a unique address throughout the world, this value can be safely used for identification purposes. It is possible that this property will return an empty string, which indicates that it could not find a network adapter.

If more than one physical network adapter is installed on the system, this property will return the MAC address of the first adapter that it finds.

Data Type

String

See Also

[AdapterAddress Property](#), [AdapterCount Property](#), [LocalAddress Property](#)

Protocol Property

Gets and sets the protocol that should be used to create the socket.

Syntax

object.Protocol [= *protocol*]

Remarks

The **Protocol** property specifies the type of socket that is to be created. This property may only be set before a socket has been created, or after it has been closed. Supported socket protocols are:

Value	Description
swProtocolTcp	Specifies the User Datagram Protocol. This is a stateless, peer-to-peer message oriented protocol, with the data sent in discrete packets. UDP is a simpler network protocol that does not have the inherent reliability of TCP, but it has less overhead and is ideal for real-time applications where a dropped packet is preferable to the delay of waiting for a packet to be retransmitted. It also supports the broadcasting of datagrams over local networks, and is commonly used by services that must exchange a relatively small amount of data with a large number of clients.
swProtocolUdp	Specifies the User Datagram Protocol. This is a stateless, peer-to-peer message oriented protocol, with the data sent in discrete packets. UDP is a simpler network protocol that does not have the inherent reliability of TCP, but it has less overhead and is ideal for real-time applications where a dropped packet is preferable to the delay of waiting for a packet to be retransmitted. It also supports the broadcasting of datagrams over local networks, and is commonly used by services that must exchange a relatively small amount of data with a large number of clients.
swProtocolRaw	Raw sockets. This socket type is for special purpose applications which need access to the IP datagram. It is not supported on all platforms and should only be used if required.

The default value for this property is **swProtocolTcp**.

Data Type

Integer (Int32)

See Also

[Bind Method](#), [Connect Method](#)

RemotePort Property

Gets and sets the port number for a remote connection.

Syntax

object.RemotePort [= *portno*%]

Remarks

The **RemotePort** property is used to set the port number that the control will use to establish a connection with the remote host.

Data Type

Integer (Int32)

See Also

[HostAddress Property](#), [HostName Property](#), [LocalPort Property](#)

ReservedPort Property

Set or return if a reserved local port number should be allocated.

Syntax

object.ReservedPort [= { True | False }]

Remarks

The **ReservedPort** property determines if a reserved local port number is used by the control when the socket is created (reserved port numbers are in the range of 513 through 1023, inclusive). Some application protocols require that the client bind to a local port number in this range. By setting the **LocalPort** property to 0 and the **ReservedPort** property to True, a reserved port number will be used when the socket is created. The default value for this property is False, which specifies that a standard port number with a value of 1024 or higher will be bound to the socket unless the **LocalPort** property is explicitly set to a non-zero value. Reserved ports should only be used by those applications that expressly need them to implement a specific protocol.

It is possible that the error **swErrorAddressInUse** will be returned when attempting to connect using a reserved port number. The value of the **LocalPort** property will contain the reserved port number that could not be used.

Data Type

Boolean

See Also

[LocalPort Property](#), [RemotePort Property](#)

ReuseAddress Property

Set or return if a local socket address can be reused by the application.

Syntax

`object.ReuseAddress [= { True | False } ]`

Remarks

Setting this property to a value of true allows the address that the socket is listening on to be reused.

When a listening socket is closed, the socket will normally go into a TIME-WAIT state where the local address and port number cannot be immediately reused. A consequence of this is that calling the **Disconnect** method immediately followed by the **Listen** method using the same address and port number values may result in an error indicating that the specified address is already in use. By setting this property to True, that error is avoided and the listening socket can be created immediately without waiting for the TIME-WAIT period to elapse.

Data Type

Boolean

See Also

[Broadcast Property](#), [InLine Property](#), [NoDelay Property](#), [KeepAlive Property](#), [Route Property](#)

Secure Property

Set or return if a connection to the server is secure.

Syntax

object.Secure [= { True | False }]

Remarks

The **Secure** property determines if a secure connection is established to the server. The default value for this property is False, which specifies that a standard connection to the server is used. To establish a secure connection, the application should set this property value to True prior to calling the **Connect** method. Once the connection has been established, the client may request files or submit queries to the server as with standard connections.

It is possible for an application to establish a non-secure connection, and then switch to a secure connection at some later point during the session. Initially set the **Secure** property to False, then connect to the server normally. Once the connection has been established, setting the **Secure** property to True will cause the control to negotiate a secure connection with the remote host. If the socket was created using the **Accept** method, the control will block and wait for the client to begin the negotiation. If the socket was created using the **Connect** method, it will immediately begin the negotiation with the server. Note that if a non-blocking (asynchronous) socket is being used, the application must wait to set the **Secure** property to True after the **OnConnect** event has fired.

Setting the **Secure** property to False during a connection will cause the control to send a shutdown message to the remote host. This may cause which may cause it to terminate the connection, however it will not close the socket. It is recommended that applications do not set the **Secure** property to False after a secure connection has been established, and instead use the **Disconnect** method to close the connection.

It is recommended that the application use exception handling to catch any errors that may occur when changing the value of this property. If the control is unable to initialize the Windows security libraries, an exception will be thrown when this property value is modified.

Data Type

Boolean

Example

The following example establishes a secure connection to a web server:

```
SocketWrench1.HostName = strHostName
SocketWrench1.RemotePort = 443
SocketWrench1.Secure = True

nError = SocketWrench1.Connect()
If nError > 0 Then
    MsgBox "Unable to connect to server " & strHostName, vbExclamation
    Exit Sub
End If

If SocketWrench1.CertificateStatus <> swCertificateValid Then
    nResult = MsgBox("The server certificate could not be validated" & vbCrLf & _
        "Are you sure you wish to continue?", vbYesNo)

    If nResult = vbNo Then
```

```
        SocketWrench1.Disconnect
    Exit Sub
End If
End If
```

SecureCipher Property

Return the encryption algorithm used to establish the secure connection with the server.

Syntax

`object.SecureCipher`

Remarks

The **SecureCipher** property returns an integer value which identifies the algorithm used to encrypt the data stream. This property may return one of the following values:

Value	Description
swCipherNone	No cipher has been selected. This is not a secure connection with the server.
swCipherRC2	The RC2 block cipher was selected. This is a variable key length cipher which supports keys between 40- and 128-bits in length, in 8-bit increments.
swCipherRC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40- and 128-bits in length, in 8-bit increments.
swCipherRC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.
swCipherDES	The DES (Data Encryption Standard) block cipher was selected. This is a fixed key length cipher using 56-bit keys.
swCipherDES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively using a 168-bit key length.
swCipherDESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.
swCipherAES	The Advanced Encryption Standard cipher (also known as the Rijndael cipher) is a fixed block size cipher which use a key size of 128, 192 or 256 bits. This cipher is supported on Windows XP SP3 and later versions of the operating system.
swCipherSkipjack	The Skipjack block cipher was selected. This is a fixed key length cipher, using 80-bit keys.
swCipherBlowfish	The Blowfish block cipher was selected. This is a variable key length cipher up to 448 bits, using a 64-bit block size.

If a secure connection has not been established, this property will return a value of zero.

Data Type

Integer (Int32)

See Also

[CipherStrength Property](#), [HashStrength Property](#), [Secure Property](#), [SecureHash Property](#), [SecureKeyExchange Property](#), [SecureProtocol Property](#)

SecureHash Property

Return the message digest selected when establishing the secure connection with the server.

Syntax

object.SecureHash

Remarks

The **SecureHash** property returns an integer value which identifies the message digest algorithm that was selected when a secure connection is established. This property may return one of the following values:

Value	Description
swHashMD5	The MD5 algorithm was selected. This algorithm has been deprecated and is no longer considered to be cryptographically secure.
swHashSHA1	The SHA-1 algorithm was selected. This algorithm has been deprecated and is no longer considered to be cryptographically secure.
swHashSHA256	The SHA-256 algorithm has been selected.
swHashSHA384	The SHA-384 algorithm has been selected.
swHashSHA512	The SHA-512 algorithm has been selected.

If a secure connection has not been established, this property will return a value of zero.

Data Type

Integer (Int32)

See Also

[CipherStrength Property](#), [HashStrength Property](#), [Secure Property](#), [SecureCipher Property](#), [SecureKeyExchange Property](#), [SecureProtocol Property](#)

SecureKeyExchange Property

Return the key exchange algorithm used to establish the secure connection with the server.

Syntax

`object.SecureKeyExchange`

Remarks

The **SecureKeyExchange** property returns an integer value which identifies the key-exchange algorithm used when establishing a secure connection. This property may return one of the following values:

Value	Description
swKeyExchangeNone	No key exchange algorithm has been selected. This is not a secure connection with the server.
swKeyExchangeRSA	The RSA public key exchange algorithm has been selected.
swKeyExchangeKEA	The KEA public key exchange algorithm has been selected. This is an improved version of the Diffie-Hellman public key algorithm.
swKeyExchangeDH	The Diffie-Hellman public key exchange algorithm has been selected.
swKeyExchangeECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography. This key exchange algorithm is only supported on Windows XP SP3 and later versions of the operating system.

If a secure connection has not been established, this property will return a value of zero.

Data Type

Integer (Int32)

See Also

[CipherStrength Property](#), [HashStrength Property](#), [Secure Property](#), [SecureCipher Property](#), [SecureHash Property](#), [SecureProtocol Property](#)

SecureProtocol Property

Gets and sets the security protocol used to establish the secure connection with the server.

Syntax

object.SecureProtocol [= *protocol*]

Remarks

The **SecureProtocol** property can be used to specify the security protocol to be used when establishing a secure connection with a server. By default, the control will attempt to use TLS 1.3 to establish the connection. If TLS 1.3 is not supported, TLS 1.2 will be used. The appropriate protocol is automatically selected based on the capabilities of both the client and server.

It is recommended that you only change this property value if you fully understand the implications of doing so. Assigning a value to this property will override the default and force the control to attempt to use only the protocol specified. One or more of the following values may be used:

Value	Description
stProtocolNone	No security protocol has been selected. A secure connection has not been established.
stProtocolTLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
stProtocolTLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
stProtocolTLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
stProtocolTLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

Multiple security protocols may be specified by combining them using a bitwise Or operator. After a connection has been established, reading this property will identify the protocol that was selected to establish the connection. Attempting to set this property after a connection has been established will result in an exception being thrown. This property should only be set after setting the **Secure** property to True and before calling the **Connect** method.

Data Type

Integer (Int32)

See Also

[CipherStrength Property](#), [HashStrength Property](#), [Secure Property](#), [SecureCipher Property](#), [SecureHash Property](#), [SecureKeyExchange Property](#)

ThrowError Property

Enables or disables error handling by the application.

Syntax

object.ThrowError = { True | False }

Remarks

Error handling for methods can be performed using either return codes or exceptions, depending on the value of this property.

If the **ThrowError** property is set to False, methods will return a status value indicating success or failure. Applications should check the return value of each method and use the **LastError** and **LastErrorString** properties to determine the cause of any error.

If the **ThrowError** property is set to True, errors occurring within the control will be raised to the host application as ActiveX exceptions. In addition, the **OnError** event will fire. This allows applications to use language-specific exception handling mechanisms, such as Visual Basic error handling, instead of checking individual return values after each method call.

Even when the **ThrowError** property is set to True, the **LastError** and **LastErrorString** properties will still be updated with information about the most recent error.

If an error occurs while accessing a property value, an exception will be raised regardless of the value of the **ThrowError** property. However, the **OnError** event will not be fired for property access errors.

Data Type

Boolean

Example

The following example handles errors by checking the return code of a method:

```
Dim lResult As Long

Socket1.ThrowError = False
lResult = Socket1.Connect

If lResult <> 0 Then
    MsgBox "Error on Connect: " & lResult
    Exit Sub
End If
```

The following example handles errors by throwing them to the container (VB):

```
On Error Resume Next: Err.Clear

Socket1.ThrowError = True
Socket1.Connect

If Err.Number <> 0
    MsgBox Err.Description, vbExclamation
    Exit Sub
End If
On Error GoTo 0
```

See Also

Timeout Property

Gets and sets the amount of time until a blocking operation fails.

Syntax

object.Timeout [= *seconds*]

Remarks

Setting this property specifies the number of seconds until a blocking operation fails and the control returns an error.

For backwards compatibility with previous versions of the control, if a value greater than 1000 is specified when setting the property, the control assumes that milliseconds were intended and adjusts the value accordingly.

Data Type

Integer (Int32)

See Also

[LastError Property](#), [OnError Event](#), [OnTimeout Event](#)

Trace Property

Enable or disable network function level logging.

Syntax

`object.Trace [= { True | False } ]`

Remarks

The **Trace** property is used to enable or disable the logging of network function calls. When enabled, each function call is logged to a file, including the function parameters, return value and error code if applicable. This facility can be enabled and disabled at run time, and the trace log file can be specified by setting the **TraceFile** property. All function calls that are being logged are appended to the trace file, if it exists. If no log file exists when tracing is enabled, the file is created.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

Data Type

Boolean

See Also

[TraceFile Property](#), [TraceFlags Property](#)

TraceFile Property

Gets and sets the name of the file to use when logging network function calls.

Syntax

`object.TraceFile [= filename ]`

Remarks

The **TraceFile** property is used to specify the name of the file that is created when logging is enabled. If this property is set to an empty string (the default value), then a file named **SocketTools.log** is created in the current user's Documents folder. It is recommended that you always specify a complete path to the log file. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

If the file exists, the output is appended to the file, otherwise the file is created. Since logging is enabled per-process, the log file is shared by all instances of the controls being used. If you create multiple instances of the control, you only need to enable logging for a single instance. Because log files can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "0x". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxx:xxxx:xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, the control is attempting to connect to a system with the IPv4 address 192.0.0.1 on port 1234.

If the log file cannot be created, or the user does not have permission to modify an existing file, the error is silently ignored and no output will be generated.

Data Type

String

See Also

TraceFlags Property

Gets and sets the network function logging flags.

Syntax

`object.TraceFlags [= flags ]`

Remarks

The **TraceFlags** property is used to specify the type of information written to the trace file when socket function tracing is enabled. The following values may be used:

Value	Description
dnsTraceInfo	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
dnsTraceError	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
dnsTraceWarning	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
dnsTraceHexDump	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
dnsTraceTruncate	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.

Since logging is enabled per-process, the trace flags are shared by all instances of the control being used. If multiple controls have tracing enabled, the **TraceFlags** property should be set to the same value for each control. Changing the trace flags for any one instance of the control will affect the logging performed for all other instances used by the application.

Warnings are generated when a non-fatal error is returned by a Windows Sockets function. For example, if data is being written through the control and an error indicating that the operation would block is returned, only a warning is logged since the application simply needs to attempt to write the data at a later time.

Data Type

Integer (Int32)

See Also

[Trace Property](#), [TraceFile Property](#)

Urgent Property

Send or receive urgent data.

Syntax

object.**Urgent** [= { True | False }]

Remarks

This boolean property affects how the **Read** and **Write** methods read or write data to the socket. If set to a value of true, urgent (out-of-band) data will be read or written. All reads or writes of urgent data are unbuffered. The property value will automatically be reset to a value of false after the socket has been read or written.

Note: Not all implementations may support more than one byte of urgent data if the data is not being received in-line. Refer to the **InLine** property for additional information.

Data Type

Boolean

See Also

[InLine Property](#), [OnRead Event](#)

Version Property

Return the current version of the control.

Syntax

object.Version

Remarks

The **Version** property returns the current version of the object. This can be used by an application for validation purposes. The version returned is composed of four numbers, separated by periods. The first number is the major version number, the second number is the minor version number, the third is the build number and the fourth is the revision number.

Data Type

String

VpnAdapter Property

Return the name of the active VPN adapter.

Syntax

object.**VpnAdapter**

Remarks

The **VpnAdapter** property attempts to detect if the system is currently using a Virtual Private Network (VPN) connection. The detection logic is based on identifying active network adapters with names or descriptions that match known VPN software or common VPN adapter naming conventions, while explicitly excluding adapters associated with virtualization platforms (such as Hyper-V, VMware, and VirtualBox), loopback interfaces, and other non-VPN virtual adapters.

Because there is no industry standard for how VPN clients are identified at the network adapter level, this function uses a heuristic approach and cannot guarantee detection in every scenario. Some VPN clients may use custom adapter names or attempt to obscure their presence, and new VPN software may not be recognized until the internal detection list is updated. There is also a small chance that non-VPN software using similar naming conventions could result in a false positive.

The value of this property should be treated as a hint for diagnostic or troubleshooting purposes. It should not be used to restrict access to your application or deny service to users based solely on the possible presence of a VPN connection. If you wish to determine the IP address assigned to the VPN adapter, check the value of the **VpnAddress** property.

If no active VPN adapter is detected, this property will return an empty string.

Data Type

String

See Also

[ExternalAddress Property](#), [HostAddress Property](#), [LocalAddress Property](#), [VpnAddress Property](#)

VpnAddress Property

Return the local IP address assigned to the active VPN adapter.

Syntax

object.VpnAddress

Remarks

The **VpnAddress** property returns the IP address assigned to the active VPN connection. This property uses heuristics to detect if the system is currently using a Virtual Private Network (VPN) connection. Because there is no industry standard for how VPN adapters are identified, it is possible a VPN may not be detected and the property will return an empty string. If the property does return an IP address, the **VpnAdapter** property will return the name of the VPN adapter.

If this property returns an IP address, it will be the local address bound to the VPN adapter, not the external IP address. You can check the value of the **ExternalAddress** property to determine what external IP address has been assigned to the VPN adapter. By default, this property will prefer IPv4 addresses and will only return an IPv6 address if the VPN adapter has not been assigned an IPv4 address.

Data Type

String

See Also

[ExternalAddress Property](#), [HostAddress Property](#), [LocalAddress Property](#), [VpnAdapter Property](#)

SocketWrench Control Methods

Method	Description
Abort	Terminate the connection with a remote host
Accept	Accepts a client connection on a listening socket
Bind	Bind the socket to the specified local address and port number
Cancel	Cancels the current blocking network operation
Connect	Establish a connection with a server
ConnectUrl	Establish a connection with a server using a URL
Disconnect	Terminate the connection with a remote host
Flush	Flush the contents of the send and receive socket buffers
Initialize	Initialize the control and validate the runtime license key
Listen	Listen for incoming connections
Peek	Return data read from the socket, but do not remove it from the socket buffer
Read	Return data read from the socket
ReadByte	Read a single byte of data from the socket
ReadLine	Read a line of data from the socket, storing it in a string buffer
ReadStream	Read a stream of data from the socket, returning when all data has been read
Reject	Reject a pending client connection
Reset	Reset the internal state of the control
Resolve	Resolves a host name to a host IP address
Shutdown	Stop sending or receiving data on the socket
StoreStream	Read a stream of data from the remote host, storing it in a file
Uninitialize	Uninitialize the control and release any system resources that were allocated
Write	Write data to the socket
WriteByte	Write a single byte of data to the socket
WriteLine	Write a line of data to the socket, terminated with a carriage-return and linefeed
WriteStream	Write a stream of data to the socket, returning when all data has been written

Abort Method

Terminate the connection with a remote host.

Syntax

object.Abort

Parameters

None.

Return Value

A value of zero is returned if the connection was terminated successfully. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **Abort** method immediately closes the socket, without waiting for any remaining data to be written out. This method should only be used when the connection must be closed immediately before the application terminates.

See Also

[Connect Method](#), [Disconnect Method](#)

Accept Method

Accepts a client connection on a listening socket.

Syntax

object.Accept (*Handle*, [*Options*])

Parameters

Handle

An integer value that specifies the handle of the listening socket. If the control that invokes this method is not the listening socket, then the listening socket may continue to listen for incoming connections. If the control invokes this method using its own **Handle** property, it will stop listening for connections.

Options

An optional integer value that specifies one or more options. If this parameter is omitted, the values of the properties listed below will be used to determine the default options when accepting the connection.

Value	Property
swOptionNone	None
swOptionDontRoute	Route = False
swOptionKeepAlive	KeepAlive = True
swOptionReuseAddress	ReuseAddress = True
swOptionNoDelay	NoDelay = True
swOptionInLine	InLine = True
swOptionSecure	Secure = True

Return Value

A value of zero is returned if the acceptance was successful. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

To set the **Options** argument explicitly, set it as a combination of values chosen from the table above. Use the appropriate constant if you wish the attribute corresponding to the property to be True, except for the **Route** property. Specifying the *swOptionDontRoute* option is the same as setting the Route property to a value of False.

See Also

[Backlog Property](#), [Handle Property](#), [Listen Method](#), [Reject Method](#), [OnAccept Event](#)

Bind Method

Bind the socket to the specified local address and port number.

Syntax

object.Bind([*LocalAddress*], [*LocalPort*], [*Protocol*], [*Timeout*], [*Options*])

Parameters

LocalAddress

An optional string value that specifies the local Internet address that the socket should be bound to. To bind to any valid network interface on the local system, specify the address 0.0.0.0. Applications should only specify a particular address if it is absolutely necessary. In most cases a local address is not required when establishing a client connection. If this value is not specified, the **LocalAddress** property will be used to determine the default value.

LocalPort

An optional integer value that specifies a local port number that the socket should be bound to. To bind to any available port number, specify a port number of 0. Applications should only specify a particular port number if it is absolutely necessary. The maximum valid port number is 65535. If this argument is not specified, the **LocalPort** property will be used to determine the default value.

Protocol

An optional integer value that specifies the protocol that should be used when establishing the connection. If this argument is not specified, the value of the **Protocol** property will be used as the default. One of the following values may be used:

Value	Description
swProtocolTcp	Specifies the Transmission Control Protocol. This protocol provides a reliable means of communication between two computers using a client/server architecture. The data is exchanged as a stream of bytes, with the protocol ensuring that the data arrives in the same byte order that it was sent, without duplication or missing data. This protocol is designed for accuracy and not speed, therefore TCP can sometimes incur relatively long delays while waiting for out-of-order packets and the retransmission of data which can make it unsuitable for some applications such as streaming video or audio.
swProtocolUdp	Specifies the User Datagram Protocol. This is a stateless, peer-to-peer message oriented protocol, with the data sent in discrete packets. UDP is a simpler network protocol that does not have the inherent reliability of TCP, but it has less overhead and is ideal for real-time applications where a dropped packet is preferable to the delay of waiting for a packet to be retransmitted. It also supports the broadcasting of datagrams over local networks, and is commonly used by services that must exchange a relatively small amount of data with a large number of clients.

Timeout

An optional integer value that specifies the amount of time until a blocking operation fails. If this argument is not specified, the **Timeout** property will be used to determine the default value.

Options

An optional integer value that specifies one or more options which are to be used when establishing the connection. The value is created by combining the options using a bitwise Or operator. Note that if this argument is specified, it will override any property values that are related to that option.

Value	Description
swOptionBroadcast	This option specifies that broadcasting should be enabled for datagrams. This option is invalid for stream sockets.
swOptionDontRoute	This option specifies default routing should not be used. This option should not be specified unless absolutely necessary.
swOptionKeepAlive	This option specifies that packets are to be sent to the remote system when no data is being exchanged to keep the connection active. This option is only valid for stream sockets.
swOptionReuseAddress	This option specifies the local address can be reused. This option is commonly used by server applications.
swOptionNoDelay	This option disables the Nagle algorithm, which buffers unacknowledged data and insures that a full-size packet can be sent to the remote host.
swOptionInLine	This option specifies that out-of-band data should be received inline with the standard data stream. This option is only valid for stream sockets.

Return Value

A value of zero is returned if the connection was successful. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

When this method is called with **swProtocolUdp** as the specified protocol, it will immediately create the datagram socket and bind it to the given address. When this method is called with **swProtocolTcp** as the specified protocol, creation of the socket is deferred until the **Connect** method is called. For stream sockets, this method will set the local address, port number and default options used when the socket is actually created.

See Also

[Broadcast Property](#), [LocalAddress Property](#), [LocalPort Property](#), [Timeout Property](#), [Connect Method](#), [Disconnect Method](#)

Cancel Method

Cancels the current blocking network operation.

Syntax

object.Cancel

Parameters

None.

Return Value

None.

Remarks

The **Cancel** method cancels any blocking network operation in the current thread. This is typically used inside an event handler, causing the blocking method to return to the caller with an error indicating that the current operation was canceled. This method sets an internal flag that is periodically checked during a blocking operation, such as waiting for more data to arrive. If the current thread is not blocked at the time that this method is called, it will have no effect.

See Also

[Reset Method](#)

Connect Method

Establish a connection with a server.

Syntax

```
object.Connect( [RemoteAddress], [RemotePort], [Protocol], [Timeout], [Options], [LocalAddress],  
[LocalPort] )
```

Parameters

RemoteAddress

An optional string value that specifies the host name or IP address of the server. If this parameter is omitted, it defaults to the value of the **HostAddress** property if it is defined; otherwise, it defaults to the value of the **HostName** property.

RemotePort

An optional integer value that specifies the port number that the server is using to listen for connections. If this parameter is omitted, the **RemotePort** property will be used to determine the default value.

Protocol

An optional integer value that specifies the protocol that should be used when establishing the connection. If this parameter is omitted, the **Protocol** property will be used to determine the default value. It may be one of the following values:

Value	Description
swProtocolTcp	The connection will use the Transmission Control Protocol. This protocol provides a reliable means of communication between two computers using a client/server architecture. The data is exchanged as a stream of bytes, with the protocol ensuring that the data arrives in the same byte order that it was sent, without duplication or missing data. This protocol is designed for accuracy and not speed, therefore TCP can sometimes incur relatively long delays while waiting for out-of-order packets and the retransmission of data which can make it unsuitable for some applications such as streaming video or audio.
swProtocolUdp	The connection will use the User Datagram Protocol. This is a stateless, peer-to-peer message oriented protocol, with the data sent in discrete packets. UDP is a simpler network protocol that does not have the inherent reliability of TCP, but it has less overhead and is ideal for real-time applications where a dropped packet is preferable to the delay of waiting for a packet to be acknowledged or retransmitted. It also supports the broadcasting of datagrams over local networks, and is commonly used by services that must exchange a relatively small amount of data with a large number of clients.

Timeout

An optional integer value that specifies the amount of time until a blocking operation fails. If this parameter is omitted, the **Timeout** property will be used to determine the default value.

Options

An optional integer value that specifies one or more socket options which are to be used when

establishing the connection. The value is created by combining the options using a bitwise Or operator. Note that if this argument is specified, it will override any property values that are related to that option.

Value	Description
swOptionBroadcast	This option specifies that broadcasting should be enabled for datagrams. This option is invalid for stream sockets.
swOptionDontRoute	This option specifies default routing should not be used. This option should not be specified unless absolutely necessary.
swOptionKeepAlive	This option specifies that packets are to be sent to the remote system when no data is being exchanged to keep the connection active. This is only valid for stream sockets.
swOptionNoDelay	This option disables the Nagle algorithm. By default, small amounts of data written to the socket are buffered, increasing efficiency and reducing network congestion. However, this buffering can negatively impact the responsiveness of certain applications. This option disables this buffering and immediately sends data packets as they are written to the socket.
swOptionInLine	This option specifies that out-of-band data should be received inline with the standard data stream. This option is only valid for stream sockets.
swOptionTrustedSite	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the TLS protocol.
swOptionSecure	This option specifies that a secure connection should be established with the remote host. The specific version of TLS can be specified by setting the SecureProtocol property. By default, the connection will use TLS 1.2 and the strongest cipher suites available. Older versions of Windows prior to Windows 7 and Windows Server 2008 R2 only support TLS 1.0 and secure connections will automatically downgrade on those platforms.
swOptionSecureFallback	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
swOptionPreferIPv6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.

LocalAddress

An optional string value that specifies the local IP address of the network adapter that the control

should use when establishing the connection. If this parameter is omitted, the control will bind to any suitable adapter on the local system. It is recommended that you omit this parameter when establishing a TCP connection unless you fully understand the implications of binding the socket to a specific local address.

LocalPort

An optional integer value that specifies the local port number that the control should use when establishing the connection. If this argument is not specified, an appropriate local port number will be automatically allocated for the connection. It is recommended that you omit this parameter when establishing a TCP connection unless you fully understand the implications of binding the socket to a specific local port.

Return Value

A value of zero is returned if the connection was successful. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

ConnectUrl Method

Establish a connection with a server using a URL.

Syntax

object.ConnectUrl([*Url*], [*Timeout*], [*Options*])

Parameters

Url

A string value which specifies a URL used when establishing the connection. This parameter cannot be omitted and it cannot be an empty string. If a non-standard URI scheme is used, the port number must be explicitly specified or the method will fail. See the remarks below for more information on the format supported by this method.

Timeout

An optional integer value that specifies the amount of time until a blocking operation fails. If this parameter is omitted, the **Timeout** property will be used to determine the default value.

Options

An optional integer value that specifies one or more socket options which are to be used when establishing the connection. The value is created by combining the options using a bitwise Or operator. Note that if this argument is specified, it will override any property values that are related to that option.

Value	Description
swOptionKeepAlive	This option specifies that packets are to be sent to the remote system when no data is being exchanged to keep the connection active. This is only valid for stream sockets.
swOptionNoDelay	This option disables the Nagle algorithm. By default, small amounts of data written to the socket are buffered, increasing efficiency and reducing network congestion. However, this buffering can negatively impact the responsiveness of certain applications. This option disables this buffering and immediately sends data packets as they are written to the socket.
swOptionInLine	This option specifies that out-of-band data should be received inline with the standard data stream. This option is only valid for stream sockets.
swOptionTrustedSite	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the TLS protocol.
swOptionSecure	This option specifies that a secure connection should be established with the remote host. The specific version of TLS can be specified by setting the SecureProtocol property. By default, the connection will use TLS 1.2 and the strongest cipher suites available.
swOptionSecureFallback	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this

	option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
swOptionPreferIPv6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.

Return Value

A value of zero is returned if the connection was successful. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **ConnectUrl** method provides a simplified interface which can be used to establish a connection using a URL. This method can only be used to establish connections using TCP and does not currently support the use of URLs to connect with a service which uses UDP. The general format of the URL should look like this:

```
[scheme]:// [[username : password] @] hostname [:port] / [path;parameters
...]
```

This method recognizes most standard URI schemes which use this format. The host name and port number specified in the URL will be used to establish a connection and the remaining information will be discarded. If the URL does not explicitly specify a port number, the default port number associated with the scheme will be used as the default value. For example, consider the following:

```
https://www.example.com
```

In this example, there is no port number specified; instead, the default port for the **https://** scheme would be used, which is port 443. The host name **www.example.com** would be resolved into an IP address and the connection established on port 443. This method will also recognize a simpler format which only includes the host name and port number without a URI scheme, such as:

```
www.example.com:443
```

When used in this way, the port number must always be provided. Without a URI scheme or an explicit port number, the method cannot determine what port number should be used when establishing the connection. The same also applies if a custom, non-standard URI scheme is provided which is not recognized.

If the URI scheme specifies a secure protocol which requires implicit TLS, this method will automatically enable security options. For example, providing a URL which uses the **https://** scheme will automatically enable a secure connection regardless if the **Options** parameter includes that option. If a URI scheme is used in conjunction with a port number associated with a secure service, security will also be enabled for that connection. For example:

```
http://www.example.com:443
```

The standard **http://** scheme is used which does not indicate a secure connection. However, since port 443 is the standard port designated for a secure HTTP connection, a secure connection will be enabled by default, even if **swOptionSecure** has not been specified by the caller. Alternatively, if a custom port number is specified in the URL or the scheme is not recognized as one which requires implicit TLS, security options will not be automatically enabled for the connection.

The host name portion of the URL can be specified as either a domain name or an IP address. Because an IPv6 address can contain colon characters, you must enclose the entire address in bracket [] characters. If this is not done, this method will return an error indicating the port number is invalid. For example, the URL **https://[2001:db8:0:0:1::128]/** uses an IPv6 host address and this would be considered valid. Without the brackets, this URL would not be accepted.

Important: The URL provided to this method will only be used to establish a connection with a server. This is a general purpose method which does not enable support for any particular application protocol and all implementation details are the responsibility of your application. If you require higher-level support for a specific Internet protocol, the SocketTools ActiveX Edition provides a comprehensive collection of higher-level controls which can be used to access those services.

If you use the **swOptionSecure** option to enable a secure connection, the connection will always use implicit TLS. This means a secure session will be initiated immediately after the socket connection has been established with the server. A common example of a service which uses implicit TLS is the HTTPS protocol. Another type of secure connection is one that uses explicit TLS. This is when the client establishes a normal (non-secure) connection with the server and then explicitly switches to using a secure connection, typically by sending a command. If the server you are connecting to requires explicit TLS, you should not specify the **dwOptionSecure** option. Instead, connect without this option and then set the **Secure** property to True when you are ready to initiate the TLS handshake.

[HostName Property](#), [KeepAlive Property](#), [NoDelay Property](#), [Options Property](#), [Secure Property](#), [Timeout Property](#), [Disconnect Method](#)

Disconnect Method

Terminate the connection with a remote host.

Syntax

object.Disconnect

Parameters

None.

Return Value

A value of zero is returned if the connection was terminated successfully. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

This method terminates the network connection with the server.

See Also

[Connect Method](#)

Flush Method

Flush the contents of the send and receive socket buffers.

Syntax

object.Flush

Parameters

None.

Return Value

A value of zero is returned if the socket buffers were flushed successfully. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **Flush** method will flush any data waiting to be read or written to the remote host . It is important to note that this method is not similar to flushing data to a disk file; it does not ensure that a specific block of data has been written to the socket. For example, you should never call this function immediately after calling the **Write** or **WriteLine** methods, or prior to calling the **Disconnect** method.

An application should not use the **Flush** method under normal circumstances. This method is only to be used when the application needs to immediately return the socket to an inactive state with no pending data to be read or written. Calling this method may result in data loss and should only be used if you understand the implications of discarding any data which has been sent by the remote host.

See Also

[IsReadable Property](#), [IsWritable Property](#), [Read Method](#), [Write Method](#)

Initialize Method

Initialize the control and validate the runtime license key.

Syntax

```
object.Initialize( [LicenseKey] )
```

Parameters

LicenseKey

An optional string value which specifies a runtime license key used to initialize the control. If the license key is omitted or passed as an empty string, a development license must be installed on the local system.

Return Value

A value of zero is returned if the control was initialized successfully. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

This method dynamically loads other system libraries and allocates thread local storage. In most cases, it is not necessary to call this method directly because it is automatically invoked when an instance of the control is created by the container. However, if the control is created dynamically using **CreateObject** or a similar method, this must be the first method that is called before you attempt to modify any property values or invoke other methods. Failure to initialize the control may result in subsequent errors and/or cause an exception to be raised.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the control will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the control was created.

If the control is being used within another DLL, it is important that you do not attempt to create an instance of the control or call the **Initialize** method from within the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is written in C++ and it is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for any static and global C++ objects and has the same restrictions.

Example

```
Set objSocket = CreateObject("SocketTools.SocketWrench.11")

nError = objSocket.Initialize(strLicenseKey)
If nError > 0 Then
    MsgBox "Unable to initialize SocketWrench"
End
End If
```

See Also

[IsInitialized Property](#), [Connect Method](#), [Reset Method](#), [Uninitialize Method](#)

Listen Method

Listen for incoming connections.

Syntax

object.Listen([*LocalAddress*], [*LocalPort*], [*Backlog*])

Parameters

LocalAddress

An optional string value that specifies the IP address the control should use when listening for connection requests. If this argument is not specified, the control will bind to any suitable IPv4 interface on the local system.

LocalPort

An optional integer value that specifies the local port number that be used to listen for connections. If this parameter is omitted, the **LocalPort** property will be used to determine the default port number. If this value is zero, the listening socket will be bound to a random port number.

Backlog

An optional integer value that specifies the maximum size of the queue used to manage pending connections to the service. If this parameter is set to value which exceeds the maximum size allowed by the operating system, it will be silently adjusted to the nearest legal value. If this parameter is omitted, the **Backlog** property will be used to determine the default value.

Return Value

A value of zero is returned if the operation was successful, otherwise a non-zero error code is returned which indicates the cause of the failure. This method will return an error if a socket has already been created by a previous call to the **Connect** method.

Remarks

The **Listen** method causes the control to listen on a socket for incoming connections on a particular local address and local port. If an IPv6 address is specified as the local IP address, the system must have an IPv6 stack installed and configured, otherwise the method will fail.

To listen for connections on any suitable IPv4 interface, specify the special dotted-quad address "0.0.0.0". You can accept connections from clients using either IPv4 or IPv6 on the same socket by specifying the special IPv6 address "::0", however this is only supported on Windows 7 and Windows Server 2008 R2 or later platforms. If no local address is specified, then the server will only listen for connections from clients using IPv4. This behavior is by design for backwards compatibility with systems that do not have an IPv6 TCP/IP stack installed.

See Also

[Backlog Property](#), [LocalPort Property](#), [Accept Method](#), [Connect Method](#), [Reject Method](#), [OnAccept Event](#)

Peek Method

Return data read from the socket, but do not remove it from the socket buffer.

Syntax

*object.Peek(**Buffer**, [**Length**])*

Parameters

Buffer

A buffer that the data will be stored in. If the variable is a **String** then the data will be returned as a string of characters. This is the most appropriate data type to use if the server is sending data that consists of printable characters. If the server is sending binary data, it is recommended that a **Byte** array be used instead. This parameter must be passed by reference.

Length

A numeric value which specifies the number of bytes to read. Its maximum value is $2^{31}-1 = 2147483647$. This argument is required to be present for string data. If a value is specified for this argument for other permissible types of data, and it is less than number of bytes that is determined by the control, then **Length** will override the internally computed value. If the argument is omitted, then the maximum number of bytes to read is determined by the size of the buffer.

Return Value

If the method succeeds, it will return the number of bytes available to read from the socket without causing the thread to block. A return value of zero indicates that there is no data available to read at that time. If an error occurs, a value of -1 is returned.

Remarks

The **Peek** method reads the specified number of bytes from the socket and copies them into the buffer, but it does not remove the data from the internal socket buffer. Note that it is possible for the returned data to contain embedded null characters.

The data returned by the **Peek** method is not removed from the socket buffers. It must be consumed by a subsequent call to the **Read** method. The return value indicates the number of bytes that can be read in a single operation, up to the specified buffer size. However, it is important to note that it may not indicate the total amount of data available to be read from the socket at that time.

If no data is available to be read, the method will return a value of zero. Using this method in a loop to poll a non-blocking socket may cause the application to become non-responsive. To determine if there is data available to be read, use the **IsReadable** property.

See Also

[IsReadable Property](#), [Read Method](#), [ReadLine Method](#), [Write Method](#), [WriteLine Method](#), [OnRead Event](#), [OnWrite Event](#)

Read Method

Return data read from the socket.

Syntax

object.Read(*Buffer*, [*Length*], [*Options*], [*RemoteAddress*], [*RemotePort*])

Parameters

Buffer

A buffer that the data will be stored in. If the variable is a **String** then the data will be returned as a string of characters. This is the most appropriate data type to use if the server is sending data that consists of printable characters. If the server is sending binary data, a **Byte** array should be used instead. This parameter must be passed by reference.

Length

An optional integer value which specifies the number of bytes to read. Its maximum value is $2^{31}-1 = 2147483647$. This argument is required to be present for string data. If a value is specified for this argument for other permissible types of data, and it is less than number of bytes that is determined by the control, then **Length** will override the internally computed value. If the argument is omitted, then the maximum number of bytes to read is determined by the size of the buffer.

Options

An optional integer value that is reserved for future functionality and should either be omitted, or specified with a value of zero. Specifying a non-zero value will cause the method to fail and return an error.

RemoteAddress

An optional string that will contain the IP address of the remote host when the method returns. This parameter must be passed by reference. For a TCP connection, the IP address is the same value that was used to establish the connection. When reading data from a UDP socket, this is the IP address of the peer that sent the datagram. This information can be used in conjunction with the **Write** method to send a datagram back to that host. If the peer's IP address is not required, this parameter may be omitted.

RemotePort

An optional integer that will contain the port number for the remote host when the method returns. This parameter must be passed by reference. When reading a datagram from a UDP socket, this is the port number used by the peer who sent the datagram. This information can be used in conjunction with the **Write** method to send a datagram back to that host. If the peer's port number is not required, this parameter may be omitted.

Return Value

The number of bytes actually read from the socket is returned by this method. If an error occurs, a value of -1 is returned.

Remarks

The **Read** method returns data that has been read from the socket, up to the number of bytes specified. If no data is available to be read, an error will be generated if the control is non-blocking mode. If the control is in blocking mode, the program will wait until data is returned by the server or the connection is closed.

If the data contains binary characters, particularly non-printable control characters and embedded nulls, you should always provide a **Byte** array to the **Read** method. When you provide a **String** variable as the buffer, the control will process the data as text. Binary characters may be interpreted as 8-bit ANSI encoding and embedded null characters will corrupt the data. Reading the data into a byte array ensures that you receive the data exactly as it was sent by the server.

If the remote host is sending text that you want to read a line at a time, use the **ReadLine** method. If you wish to read a large amount of data using a single method call rather than making multiple calls to the **Read** method, use the **ReadStream** method.

See Also

[CodePage Property](#), [IsReadable Property](#), [ReadLine Method](#), [ReadStream Method](#) [Write Method](#), [OnRead Event](#), [OnWrite Event](#)

ReadByte Method

Read a byte of data from the socket.

Syntax

object.ReadByte

Parameters

None.

Return Value

The integer value of the byte read from the socket. If an error occurs, the method will return a value of -1 and the program should check the value of the **LastError** property to determine the specific cause of the error.

Remarks

The **ReadByte** method returns one byte of data that has been read from the socket. If no data is available to be read, an error will be generated if the control is non-blocking mode. If the control is in blocking mode, the program will stop until a byte of data is returned by the server or the connection is closed.

Note that you should not use the **ReadByte** method with a datagram socket. If you do, then only the first byte of the datagram will be returned and the remaining data will be discarded. When reading data from a datagram socket, it is recommended that you always use the **Read** method with the length argument specifying the maximum size of the datagram.

See Also

[IsReadable Property](#), [Timeout Property](#), [Read Method](#), [Write Method](#), [WriteByte Method](#), [OnRead Event](#)

ReadLine Method

Read up to a line of data from the socket and returns it in a string buffer.

Syntax

*object.ReadLine(**Buffer**, [**Length**])*

Parameters

Buffer

A buffer that the data will be stored in. If the variable is a **String** then the data will be returned as a string of characters. If the data returned by the server contains UTF-8 encoded text, it will automatically be converted to standard UTF-16 Unicode text. If you wish to read the data without conversion, provide a **Byte** array as the buffer. This parameter must be passed by reference.

Length

A numeric value which specifies the number of bytes to read. Its maximum value is $2^{31}-1 = 2147483647$. This argument is required to be present for string data. If a value is specified for this argument for other permissible types of data, and it is less than number of bytes that is determined by the control, then **Length** will override the internally computed value. If the argument is omitted, then the maximum number of bytes to read is determined by the size of the buffer.

Return Value

This method will return True if a line of data has been read. If an error occurs or there is no more data available to read, then the method will return False. It is possible for data to be returned in the string buffer even if the return value is False. Applications should check the length of the string after the method returns to determine if any data was copied into the buffer. For example, if a timeout occurs while the method is waiting for more data to arrive on the socket, it will return zero; however, data may have already been copied into the string buffer prior to the error condition. It is the responsibility of the application to process that data, regardless of the function return value.

Remarks

The **ReadLine** method reads data from the socket up to the specified number of bytes or until an end-of-line character sequence is encountered. Unlike the **Read** method which reads arbitrary bytes of data, this function is specifically designed to return a single line of text data in a string variable. When an end-of-line character sequence is encountered, the function will stop and return the data up to that point; the string will not contain the carriage-return or linefeed characters.

If multi-byte 8-bit encoded characters are read from the socket, by default they will automatically be converted to Unicode according to the value of the **CodePage** property and returned in the string buffer provided. To prevent the text from being converted to Unicode, call the **Read** method and use a byte array instead of a string variable.

There are some limitations when using the **ReadLine** method. The method should only be used to read text, never binary data. In particular, it will discard nulls, linefeed and carriage return control characters. This method will force the thread to block until an end-of-line character sequence is processed, the read operation times out or the remote host closes its end of the socket connection. If the **Blocking** property is set to False, calling this method will automatically switch the socket into a blocking mode, read the data and then restore the socket to non-blocking mode. If another socket operation is attempted while **ReadLine** is blocked waiting for data from the remote host, an error will occur. It is recommended that this method only be used with blocking socket connections.

The **Read** and **ReadLine** methods can be intermixed, however be aware that the **Read** method will consume any data that has already been buffered by the **ReadLine** method and this may have unexpected results.

See Also

[CodePage Property](#), [IsReadable Property](#), [Read Method](#), [ReadStream Method](#), [StoreStream Method](#), [Write Method](#), [WriteLine Method](#)

ReadStream Method

Read the socket and store the data stream in the specified buffer.

Syntax

object.ReadStream(*Buffer*, [*Length*], [*Marker*], [*Options*])

Parameters

Buffer

A variable that will contain the data read from the socket when the method returns. If the variable is a **String** type, then the data will be stored as a string of characters. This is the most appropriate data type to use if the server is sending text data that consists of printable characters. If the remote host is sending binary data, a **Byte** array should be used instead. This parameter must be passed by reference.

Length

A numeric variable which specifies the maximum amount of data to be read from the socket. When the method returns, this variable will be updated with the actual number of bytes read. Note that because this argument is passed by reference and modified by the method, you must provide a variable, not a numeric constant. If this argument is omitted or the value is initialized to zero, this method will read data from the socket until the remote host disconnects or an error occurs.

Marker

A string or array of bytes which is used to designate the logical end of the data stream. When this byte sequence is encountered by the method, it will stop reading and return to the caller. The buffer will contain all of the data read from the socket up to and including the end-of-stream marker. If this argument is omitted, then the function will continue to read from the socket until the maximum buffer size is reached, the remote host closes its socket or an error is encountered.

Options

An optional integer value which specifies any options to be used when reading the data stream. One or more of the following bit flags may be specified by the caller:

Value	Description
swStreamDefault	The data stream will be returned to the caller unmodified. This option should always be used with binary data or data being stored in a byte array. If no options are specified, this is the default option used by this method.
swStreamConvert	The data stream is considered to be textual and will be modified so that end-of-line character sequences are converted to follow standard Windows conventions. This will ensure that all lines of text are terminated with a carriage-return and linefeed sequence. Because this option modifies the data stream, it should never be used with binary data. Using this option may result in the amount of data returned in the buffer to be larger than the source data. For example, if the source data only terminates a line of text with a single linefeed, this option will have the effect of inserting a carriage-return character before each linefeed.

Return Value

This method returns a boolean value. If the method succeeds, the return value is True. If the function fails, the return value is False. To get extended error information, check the value of the **LastError** property.

Remarks

The **ReadStream** method enables an application to read an arbitrarily large stream of data and store it in memory, either in a string or a byte array. Unlike the **Read** method, which will return immediately when any amount of data has been read, the **ReadStream** method will only return when the buffer is full as specified by the **Length** argument, the logical end-of-stream marker has been read, the socket closed by the remote host or when an error occurs.

If the data contains binary characters, particularly non-printable control characters and embedded nulls, you should always provide a **Byte** array to the **ReadStream** method. When you provide a **String** variable as the buffer, the control will process the data as text. Binary characters may be interpreted as 8-bit ANSI encoding and embedded null characters will corrupt the data. Reading the data into a byte array ensures that you receive the data exactly as it was sent by the server.

This method will force the application to wait until the operation completes. If this method is called and the **Blocking** property is set to False, it will automatically switch the socket into a blocking mode, read the data stream and then restore the socket to non-blocking mode when it has finished. If another socket operation is attempted while **ReadStream** is blocked waiting for data from the remote host, an error will occur. It is recommended that this method only be used with blocking (synchronous) socket connections; if the application needs to establish multiple simultaneous connections, it should create worker threads to manage each connection.

It is possible for data to be returned in the buffer even if the method returns False. Applications should also check the value of the **Length** argument to determine if any data was copied into the buffer. For example, if a timeout occurs while the method is waiting for more data to arrive on the socket, it will return zero; however, data may have already been copied into the buffer prior to the error condition. It is the responsibility of the application to process that data, regardless of the method return value.

Because **ReadStream** can potentially cause the application to block for long periods of time as the data stream is being read, the control will periodically generate **OnProgress** events. An application can use this event to update the user interface as the data is being read. Note that an application should never perform a blocking operation inside the event handler.

Example

```
Dim strBuffer As String
Dim nLength As Long

nLength = 0 ' Read socket until connection is closed
If SocketWrench1.ReadStream(strBuffer, nLength, Options:=swStreamConvert) Then
    TextBox1.Text = strBuffer
End If
```

See Also

[Blocking Property](#), [CodePage Property](#), [Read Method](#), [ReadLine Method](#), [StoreStream Method](#), [WriteStream Method](#), [OnProgress Event](#)

Reject Method

Rejects a connection request from a remote host.

Syntax

object.Reject

Parameters

None.

Return Value

A value of zero is returned if the rejection was successful. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **Reject** method rejects a pending client connection and the remote host will see this as the connection being aborted. If there are no pending client connections at the time, this method will immediately return with an error indicating that the operation would cause the thread to block.

See Also

[Accept Method](#), [Listen Method](#), [OnAccept Event](#)

Reset Method

Reset the internal state of the control.

Syntax

object.Reset

Parameters

None.

Return Value

None.

Remarks

The **Reset** method resets the internal state of the control. Property values are initialized to their internal defaults, open network connections will be closed and any handles allocated by the control will be released.

See Also

[Cancel Method](#), [Initialize Method](#), [Uninitialize Method](#)

Resolve Method

Resolves a host name to a host IP address.

Syntax

object.Resolve(HostName, IpAddress)

Parameters

HostName

A string value that specifies the host name to resolve.

IpAddress

A string that will contain the IP address of the specified host when the method returns. This parameter must be passed by reference. The value that is returned may be either a dotted-quad IPv4 address or an IPv6 address, depending on the configuration of the local system and what addresses are assigned to the host name.

Return Value

A value of zero is returned if the host name could be resolved into an IP address. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **Resolve** method is used to resolve a host name into an IP address. If the host name has both an IPv4 and IPv6 address associated with it, this method will return the IPv4 address by default. If the host name only has an IPv6 address, that value will be returned if the local system has an IPv6 TCP/IP stack installed; otherwise, the method will fail with an error indicating that the host name could not be resolved.

See Also

[AutoResolve Property](#), [HostAddress Property](#), [HostFile Property](#), [HostName Property](#)

Shutdown Method

Stop sending or receiving data on the socket.

Syntax

`object.Shutdown( [Option] )`

Parameters

Option

An optional integer value that specifies the action to be taken. It may be one of the following values:

Value	Description
swShutdownRead	Disable reception of data. The application will no longer be able to receive data from the remote host. The application may continue to send data using the Write or WriteLine method until the socket is closed.
swShutdownWrite	Disable transmission of data. The application will no longer be able to send data to the remote host and the remote host will consider the socket connection to be closed. The application may continue to read any remaining data in the socket's receive buffer using the Read or ReadLine method until the socket is closed. This is the default value if this parameter is omitted.
swShutdownBoth	Disable both reception and transmission of data. If this value is specified, then the socket handle remains valid, however the client will not be able to send or receive data. The application must call the Disconnect method to close the socket.

Return Value

A value of zero is returned if the request was successful. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

In some asynchronous applications, it may be desirable for a client to inform the server that no further communication is wanted, while allowing the client to read any residual data that may reside in internal buffers on the client side. **Shutdown** accomplishes this because the socket handle is still valid after it has been called, although some or all communication with the remote host has ceased.

See Also

[Disconnect Method](#)

StoreStream Method

Reads the data stream from the socket and stores it in a specified file.

Syntax

object.StoreStream(FileName, [Length], [Offset], [Options])

Parameters

FileName

A string variable that specifies the name of the file that will contain the data read from the socket. If the file does not exist, it will be created. If the file does exist, it will be overwritten.

Length

A numeric variable which specifies the maximum amount of data to be read from the socket. When the method returns, this variable will be updated with the actual number of bytes read. Note that because this argument is passed by reference and modified by the method, you must provide a variable, not a numeric constant. If this argument is omitted or the value is initialized to zero, this method will read data from the socket until the remote host disconnects or an error occurs.

Offset

A numeric value which specifies the byte offset into the file where the method will start storing data read from the socket. Note that all data after this offset will be truncated. If this argument is omitted or a value of zero is specified the file will be completely overwritten if it already exists.

Options

An optional integer value which specifies any options to be used when reading the data stream. One or more of the following bit flags may be specified by the caller:

Value	Description
swStreamDefault	The data stream will be returned to the caller unmodified. This option should always be used with binary data or data being stored in a byte array. If no options are specified, this is the default option used by this method.
swStreamConvert	The data stream is considered to be textual and will be modified so that end-of-line character sequences are converted to follow standard Windows conventions. This will ensure that all lines of text are terminated with a carriage-return and linefeed sequence. Because this option modifies the data stream, it should never be used with binary data. Using this option may result in the amount of data returned in the buffer to be larger than the source data. For example, if the source data only terminates a line of text with a single linefeed, this option will have the effect of inserting a carriage-return character before each linefeed.

Return Value

This method returns a boolean value. If the method succeeds, the return value is True. If the function fails, the return value is False. To get extended error information, check the value of the **LastError** property.

Remarks

The **StoreStream** method enables an application to read an arbitrarily large stream of data from the socket and store it in a file. This method is essentially a simplified version of the **ReadStream** method, designed specifically to be used with files rather than strings or byte arrays.

This method will force the thread to block until the operation completes. If this method is called with the **Blocking** property set to False, it will automatically switch the socket into a blocking mode, read the data stream and then restore the socket to non-blocking mode when it has finished. If another socket operation is attempted while **StoreStream** is blocked waiting for data from the remote host, an error will occur. It is recommended that this function only be used with blocking (synchronous) socket connections; if the application needs to establish multiple simultaneous connections, it should create worker threads to manage each connection.

Because **StoreStream** can potentially cause the application to block for long periods of time as the data stream is being read, the control will periodically generate **OnProgress** events. An application can use this event to update the user interface as the data is being read. Note that an application should never perform a blocking operation inside the event handler.

See Also

[Blocking Property](#), [ReadStream Method](#), [WriteStream Method](#), [OnProgress Event](#)

Uninitialize Method

Uninitialize the control and release any system resources that were allocated.

Syntax

object.Uninitialize

Parameters

None.

Return Value

None.

Remarks

The **Uninitialize** method terminates any connection established by the control and resets the internal state of the control. This method is not typically used because any resources that have been allocated by an instance of the control will automatically be released when it is destroyed.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the control will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the control was created. An application should only call the **Uninitialize** method if it has explicitly called the **Initialize** method.

See Also

[Initialize Method](#)

Write Method

Write data to the socket.

Syntax

object.Write(*Buffer*, [*Length*], [*Options*], [*RemoteAddress*], [*RemotePort*])

Parameters

Buffer

A buffer variable that contains the data to be written to the server. If the variable is a **String** type, then the data will be written as a string of characters. This is the most appropriate data type to use if the server expects text data that consists of printable characters. If the string contains Unicode characters, it will be automatically converted to use standard UTF-8 encoding prior to being sent. If the server is expecting binary data, a **Byte** array should be used instead.

Length

An optional integer value that specifies the maximum number of bytes to send to the server. Its maximum value is $2^{31}-1 = 2147483647$. This argument is not required for string data. If a value is specified for this argument for other permissible types of data, and it is less than number of bytes that is determined by the control, then **Length** will override the internally-computed value. If the socket is non-blocking and the send fails because it could not write all of the data to the server, the **OnWrite** event will be fired when the server can be written to again.

Options

An optional integer value that is reserved for future functionality and should either be omitted, or specified with a value of zero. Specifying a non-zero value will cause the method to fail and return an error.

RemoteAddress

An optional string value that specifies the IP address of the remote host that the data will be sent to. For a TCP connection, it is recommended that this argument be omitted. If it is specified, the IP address must be the same value that was used to establish the connection. When writing data to a UDP socket, this is the IP address of the peer that will receive the datagram. This information can be used in conjunction with the **Read** method to send a datagram back to that host.

RemotePort

An optional integer value that specifies the port number on the remote host that the data will be sent to. For a TCP connection, it is recommended that this argument be omitted. If it is specified, the port number must be the same value that was used to establish the connection. When writing data on a UDP socket, this is the port number for the peer who will receive the datagram. This information can be used in conjunction with the **Read** method to send a datagram back to that host.

Return Value

This method returns the number of bytes actually written to the socket, or -1 if an error was encountered.

Remarks

The **Write** method sends the data in *buffer* to the socket. If the connection is buffered, as is typically the case, the data is copied to the send buffer and control immediately returns to the program. If the control is non-blocking and is out of buffer space, an error will be generated. If the control is blocking,

the application will wait until the data can be sent.

If the data contains binary characters, particularly non-printable control characters and embedded nulls, you should always provide a **Byte** array to the **Write** method. When you provide a **String** variable as the buffer, the control will process the data as text. If the string contains non-ASCII characters, by default they will automatically be converted to 8-bit ANSI encoded text prior to being written. Using a byte array ensures that binary data will be sent as-is without being encoded.

If you want to send text to the remote host a line at a time, use the **WriteLine** method. If you wish to send a large amount of data using a single method call rather than making multiple calls to the **Write** method, use the **WriteStream** method.

See Also

[CodePage Property](#), [IsWritable Property](#), [Timeout Property](#), [Read Method](#), [WriteLine Method](#), [WriteStream Method](#), [OnWrite Event](#)

WriteByte Method

Write a byte of data to the socket.

Syntax

object.WriteByte(*Value*)

Parameters

Value

A byte or integer value that specifies the data that should be sent to the remote host. If this parameter is a numeric value, it will be converted to its equivalent byte value and written to the socket. If the argument is a string, the first character will be written to the socket.

Return Value

This method returns a boolean value. If the byte of data was successfully written to the socket, the method will return True. If the data could not be written to the socket, the method will return False and the application should check the value of the **LastError** property to determine the exact cause of the failure.

Remarks

The **WriteByte** method writes a single byte of data to the socket. If the connection is buffered, as is typically the case, the data is copied to the send buffer and control immediately returns to the program. If the socket is non-blocking and is out of buffer space, an error will be generated. If the socket is blocking, the application will wait until the data can be sent.

If you use the **WriteByte** method with a datagram socket, the datagram will only be a single byte in length. You cannot use multiple calls to **WriteByte** to compose a single datagram.

See Also

[IsWritable Property](#), [Timeout Property](#), [Read Method](#), [ReadByte Method](#), [Write Method](#), [OnWrite Event](#)

WriteLine Method

Send a line of text to the remote host, terminated by a carriage-return and linefeed.

Syntax

object.WriteLine([*Buffer*])

Parameters

Buffer

An optional **String** value which contains the text that will be sent to the remote host. The data will always be terminated with a carriage-return and linefeed control character sequence. If this argument is omitted, then a only a carriage-return and linefeed are written to the socket. If the string contains Unicode characters, it will be automatically converted to use standard UTF-8 encoding prior to being sent. If the string contains an embedded null character, any data that follows the null character will be discarded.

Return Value

This method returns True if the contents of the string have been written to the socket. If an error occurs, the method will return False.

Remarks

The **WriteLine** method writes a line of text to the remote host and terminates the line with a carriage-return and linefeed control character sequence. Unlike the **Write** method which writes arbitrary bytes of data to the socket, this method is specifically designed to write a single line of text data from a string.

If the **Buffer** string is terminated with a linefeed (LF) or carriage return (CR) character, it will be automatically converted to a standard CRLF end-of-line sequence. Because the string will be sent with a terminating CRLF sequence, the number of characters sent to the remote host will typically be larger than the original string length (reflecting the additional CR and LF characters), unless the string was already terminated with CRLF.

If the string value passed to the **WriteLine** method is a Unicode string which contains non-ASCII characters, it will be internally converted to 8-bit ANSI encoded text before being written to the socket. The remote host must be able to recognize the encoding and process it appropriately. The **ReadLine** method will automatically convert any encoded characters that it reads from the socket back to their original Unicode encoding. The **CodePage** property can be used to change the default code page used when converting the text.

The **WriteLine** method should only be used to send text, never binary data. In particular, the function will discard any data that follows a null character and will append linefeed and carriage return control characters to the data stream. Calling this this method will force the thread to block until the complete line of text has been written, the write operation times out or the remote host aborts the connection. If this function is called with the **Blocking** property set to False, it will automatically switch the socket into a blocking mode, send the data and then restore the socket to non-blocking mode. If another socket operation is attempted while the **WriteLine** method is blocked sending data to the remote host, an error will occur. It is recommended that this method only be used with blocking socket connections.

The **Write** and **WriteLine** function calls can be safely intermixed.

See Also

[CodePage Property](#), [IsWritable Property](#), [Timeout Property](#), [Read Method](#), [ReadLine Method](#), [Write Method](#), [WriteStream Method](#)

WriteStream Method

Writes data from the stream buffer to the socket.

Syntax

object.WriteStream(*Buffer*, [*Length*], [*Options*])

Parameters

Buffer

A variable that contains the data to be written to the socket. If the variable is a **String** type, then the data will be stored as a string of characters. This is the most appropriate data type to use if the server is expecting text data that consists of printable characters. If the string contains Unicode characters, it will be automatically converted to use standard UTF-8 encoding prior to being sent. If the server is expecting binary data, a **Byte** array should be used instead.

Length

A numeric variable which specifies the maximum amount of data to be written to the socket. When the method returns, this variable will be updated with the actual number of bytes written. Note that because this argument is passed by reference and modified by the method, you must provide a variable, not a numeric constant. If this argument is omitted or the value is initialized to zero, this method will automatically determine the amount of data based on the length of the string or the size of the byte array passed to the method.

Options

An optional integer value which specifies any options to be used when writing the data stream to the socket. Currently this argument is reserved for future expansion and should either be omitted or always specified with a value of zero.

Return Value

This method returns a boolean value. If the function succeeds, the return value is True. If the function fails, the return value is False. To get extended error information, check the value of the **LastError** property.

Remarks

The **WriteStream** method enables an application to write an arbitrarily large stream of data from a string buffer or byte array to the socket. Unlike the **Write** method, which may not write all of the data in a single call, the **WriteStream** method will only return when all of the data has been written or an error occurs.

If the data contains binary characters, particularly non-printable control characters and embedded nulls, you should always provide a **Byte** array to the **WriteStream** method. When you provide a **String** variable as the buffer, the control will process the data as text. If the string contains Unicode characters, they will automatically be converted to 8-bit ANSI encoded text prior to being written. Using a byte array ensures that binary data will be sent as-is without being encoded. You can change the default code page used to convert the text by setting the **CodePage** property.

This method will force the application to wait until the operation completes. If this method is called with the **Blocking** property set to False, it will automatically switch the socket into a blocking mode, write the data stream and then restore the socket to non-blocking mode when it has finished. If another socket operation is attempted while **WriteStream** is blocked sending data to the remote

host, an error will occur. It is recommended that this function only be used with blocking (synchronous) socket connections; if the application needs to establish multiple simultaneous connections, it should create worker threads to manage each connection.

It is possible that some data will have been written to the socket even if the method returns False. Applications should also check the value of the **Length** argument to determine if any data was sent. For example, if a timeout occurs while the function is waiting to write more data, it will return zero; however, some data may have already been written to the socket prior to the error condition.

Because **WriteStream** can potentially cause the application to wait for long periods of time as the data stream is being written, the control will periodically generate **OnProgress** events. An application can use this event to update the user interface as the data is being written. Note that an application should never perform a blocking operation inside the event handler.

Example

```
Dim hFile As Long
Dim nLength As Long
Dim dataBuffer() As Byte
Dim bResult As boolean

' Open the file for binary access
hFile = FreeFile()
Open strFileName For Binary Access Read As hFile

' Determine the size of the file and allocate a byte
' array large enough to store the contents
nLength = LOF(hFile)
ReDim dataBuffer(nLength - 1) As Byte

' Read the file contents into the byte array and
' then close the file
Get hFile, , dataBuffer
Close hFile

' Write the data to the socket
bResult = SocketWrench1.WriteStream(dataBuffer, nLength)
```

SocketWrench Control Events

Event	Description
OnAccept	This event occurs when a remote host connects to a listening socket
OnCancel	This event occurs when a blocking operation is canceled
OnConnect	This event occurs when a connection is established
OnDisconnect	This event occurs when a connection is terminated
OnError	This event occurs when a control error occurs
OnProgress	This event occurs as a data stream is being read or written
OnRead	This event occurs when data is available to be read
OnTimeout	This event occurs when a blocking operation times out
OnTimer	This event occurs when the control's preset timer interval expires
OnWrite	This event occurs when data can be written to the server

OnAccept Event

The **OnAccept** event is generated when a remote host connects to a listening socket.

Syntax

Sub *object_OnAccept* ([*Index As Integer*,] **ByVal** *Handle As Variant*)

Remarks

This event occurs for sockets that are listening for connections from a remote host. A connection with the remote system is not actually established until it has been accepted by the listening server. This event is only generated for asynchronous sockets when the **Blocking** property is set to False.

The **Handle** argument specifies the socket descriptor of the listening socket. To accept the connection, a socket calls its **Accept** method with argument **Handle**.

The **PeerAddress** or **PeerName** properties may be used to determine the name of the remote host that is establishing the connection. Note that this information may not be available until after the **Accept** method is called to accept the connection.

See Also

[PeerAddress Property](#), [PeerName Property](#), [Accept Method](#), [Reject Method](#)

OnCancel Event

The **OnCancel** event is generated when a blocking operation is canceled.

Syntax

Sub *object_OnCancel* ([*Index As Integer*])

Remarks

This event occurs when a blocking operation on the socket, such as sending or receiving data, is canceled with the **Cancel** method.

To assist in determining which operation was canceled, consult the **State** property.

See Also

[Cancel Method](#), [OnError Event](#)

OnConnect Event

The **OnConnect** event is generated when a connection is established.

Syntax

Sub *object_OnConnect* ([*Index As Integer*])

Remarks

The **OnConnect** event is generated when a connection is made with a remote host as a result of a **Connect** method call, or when an **Accept** method call is completed. This event is only generated for asynchronous sockets when the **Blocking** property is set to False.

See Also

[Accept Method](#), [Connect Method](#), [OnDisconnect Event](#)

OnDisconnect Event

The **OnDisconnect** event is generated when a connection is terminated.

Syntax

Sub *object_OnDisconnect* ([*Index As Integer*])

Remarks

The **OnDisconnect** event is generated when the connection is terminated by the remote host. This event is only generated for asynchronous sockets when the **Blocking** property is set to False.

See Also

[OnConnect Event](#)

OnError Event

The **OnError** event is generated when a control error occurs.

Syntax

Sub *object_OnError* ([*Index As Integer*,] **ByVal** *ErrorCode As Variant*, **ByVal** *Description As Variant*)

Remarks

This event occurs when an error occurs during a control action. Visual Basic errors do not generate this event.

The ***ErrorCode*** argument specifies the last error that has occurred. If the error is network related, the error code values returned by the control correspond to those returned by the standard Windows Sockets library.

The ***Description*** argument is a string that describes the error.

See Also

[LastError Property](#), [LastErrorString Property](#), [ThrowError Property](#)

OnProgress Event

The **OnProgress** event is generated as the data stream is being read or written.

Syntax

Sub *object_OnProgress* ([*Index As Integer*], *ByVal BytesTotal As Variant*, *ByVal BytesCopied As Variant*, *ByVal Percent As Variant*)

Remarks

The **OnProgress** event is generated as the control reads the data stream from the remote host or writes a data stream to the remote host. If the data stream contains large amounts of data, this event can be used to update a progress bar or other user-interface control to provide the user with some visual feedback. The arguments to this event are:

BytesTotal

The total amount of data being read or written in bytes. This value will be the same as the maximum size of the data stream specified by the caller. If the size was unknown or unspecified at the time, then this value will always be the same as the *BytesCopied* value.

BytesCopied

The number of bytes that have been read or written.

Percent

The percentage of data that's been read or written, expressed as an integer value between 0 and 100, inclusive. If the maximum size of the data stream was not specified by the caller, this value will always be 100.

Note that this event is only generated by the **ReadStream**, **StoreStream** and **WriteStream** methods. If the control is reading or writing data using the **Read** or **Write** methods the application is responsible for calculating the completion percentage and updating any user interface controls.

See Also

[Read Method](#), [ReadStream Method](#), [StoreStream Method](#), [Write Method](#), [WriteStream Method](#)

OnRead Event

The **OnRead** event is generated when data is available to be read.

Syntax

Sub *object_OnRead* ([*Index As Integer*])

Remarks

The **OnRead** event is generated for non-blocking sockets when data is available to be read from the server. Use the **Read** method to read the data. This event is only generated for asynchronous sockets when the **Blocking** property is set to False.

See Also

[IsReadable Property](#), [Peek Method](#), [Read Method](#), [Write Method](#), [OnWrite Event](#)

OnTimeout Event

The **OnTimeout** event is fired when a blocking operation times out.

Syntax

Sub *object_OnTimeout* ([*Index As Integer*])

Remarks

The **OnTimeout** event is generated when a blocking socket operation, such as sending or receiving data, times out. To determine which operation was in progress when the timeout occurred, consult the **State** property.

See Also

[Timeout Property](#), [OnCancel Event](#)

OnTimer Event

The **OnTimer** event is fired when the control's preset timer interval expires.

Syntax

Sub *object_OnTimer* ([*Index As Integer*])

Remarks

This event occurs when the control's timer interval has elapsed. The frequency is specified in milliseconds by setting the **Interval** property.

See Also

[Interval Property](#)

OnWrite Event

The **OnWrite** event is generated when data can be written to the server.

Syntax

Sub *object_OnWrite* ([*Index As Integer*])

Remarks

The **OnWrite** event is generated for non-blocking sockets when data can be written to the server after a previous attempt failed because it would cause the control to block. This event is only generated for asynchronous sockets when the **Blocking** property is set to False.

This event will always be generated at least one time, after the connection to the server is initially established. It will not fire again unless the **Write** method fails with the error **swErrorOperationWouldBlock**, which indicates that the socket's send buffer is full. When the socket can accept more data, this event will fire and the application can resume sending data to the remote host.

SocketWrench Control Error Codes

Value	Constant	Description
10001	swErrorNotHandleOwner	Handle not owned by the current thread
10002	swErrorFileNotFound	The specified file or directory does not exist
10003	swErrorFileNotCreated	The specified file could not be created
10004	swErrorOperationCanceled	The blocking operation has been canceled
10005	swErrorInvalidFileType	The specified file is a block or character device, not a regular file
10006	swErrorInvalidDevice	The specified device or address does not exist
10007	swErrorTooManyParameters	The maximum number of function parameters has been exceeded
10008	swErrorInvalidFileName	The specified file name contains invalid characters or is too long
10009	swErrorInvalidFileHandle	Invalid file handle passed to function
10010	swErrorFileReadFailed	Unable to read data from the specified file
10011	swErrorFileWriteFailed	Unable to write data to the specified file
10012	swErrorOutOfMemory	Out of memory
10013	swErrorAccessDenied	Access denied
10014	swErrorInvalidParameter	Invalid argument passed to function
10015	swErrorClipboardUnavailable	The system clipboard is currently unavailable
10016	swErrorClipboardEmpty	The system clipboard is empty or does not contain any text data
10017	swErrorFileEmpty	The specified file does not contain any data
10018	swErrorFileExists	The specified file already exists
10019	swErrorEndOfFile	End of file
10020	swErrorDeviceNotFound	The specified device could not be found
10021	swErrorDirectoryNotFound	The specified directory could not be found
10022	swErrorInvalidBuffer	Invalid memory address passed to function
10024	swErrorNoHandles	No more handles available to this process
10035	swErrorOperationWouldBlock	The specified operation would block the current thread
10036	swErrorOperationInProgress	A blocking operation is currently in progress
10037	swErrorAlreadyInProgress	The specified operation is already in progress
10038	swErrorInvalidHandle	Invalid handle passed to function
10039	swErrorInvalidAddress	Invalid network address specified
10040	swErrorInvalidSize	Datagram is too large to fit in specified buffer
10041	swErrorInvalidProtocol	Invalid network protocol specified
10042	swErrorProtocolNotAvailable	The specified network protocol is not available
10043	swErrorProtocolNotSupported	The specified protocol is not supported

10044	swErrorSocketNotSupported	The specified socket type is not supported
10045	swErrorInvalidOption	The specified option is invalid
10046	swErrorProtocolFamily	The specified protocol family is not supported
10047	swErrorProtocolAddress	The specified address is invalid for this protocol family
10048	swErrorAddressInUse	The specified address is in use by another process
10049	swErrorAddressUnavailable	The specified address cannot be assigned
10050	swErrorNetworkUnavailable	The networking subsystem is unavailable
10051	swErrorNetworkUnreachable	The specified network is unreachable
10052	swErrorNetworkReset	Network dropped connection on reset
10053	swErrorConnectionAborted	Connection was aborted due to timeout or other failure
10054	swErrorConnectionReset	Connection was reset by remote network
10055	swErrorOutOfBuffers	No buffer space is available
10056	swErrorAlreadyConnected	Connection already established with remote host
10057	swErrorNotConnected	No connection established with remote host
10058	swErrorConnectionShutdown	Unable to send or receive data after connection shutdown
10060	swErrorOperationTimeout	The specified operation has timed out
10061	swErrorConnectionRefused	The connection has been refused by the remote host
10064	swErrorHostUnavailable	The specified host is unavailable
10065	swErrorHostUnreachable	The specified host is unreachable
10067	swErrorTooManyProcesses	Too many processes are using the networking subsystem
10091	swErrorNetworkNotReady	Network subsystem is not ready for communication
10092	swErrorInvalidVersion	This version of the operating system is not supported
10093	swErrorNetworkNotInitialized	The networking subsystem has not been initialized
10101	swErrorRemoteShutdown	The remote host has initiated a graceful shutdown sequence
11001	swErrorInvalidHostName	The specified hostname is invalid or could not be resolved
11002	swErrorHostNameNotFound	The specified hostname could not be found
11003	swErrorHostNameRefused	Unable to resolve hostname, request refused
11004	swErrorHostNameNotResolved	Unable to resolve hostname, no address for specified host
12001	swErrorInvalidLicense	The license for this product is invalid
12002	swErrorProductNotLicensed	This product is not licensed to perform this operation
12003	swErrorNotImplemented	This function has not been implemented on this platform
12004	swErrorUnknownLocalHost	Unable to determine local host name
12005	swErrorInvalidHostAddress	Invalid host address specified
12006	swErrorInvalidServicePort	Invalid service port number specified
12007	swErrorInvalidServiceName	Invalid or unknown service name specified
12008	swErrorInvalidEventId	Invalid event identifier specified

12009	swErrorOperationNotBlocking	No blocking operation in progress on this socket
12101	swErrorSecurityNotInitialized	Unable to initialize security interface for this process
12102	swErrorSecurityContext	Unable to establish security context for this session
12103	swErrorSecurityCredentials	Unable to open client certificate store or establish client credentials
12104	swErrorSecurityCertificate	Unable to validate the certificate chain for this session
12105	swErrorSecurityDecryption	Unable to decrypt data stream
12106	swErrorSecurityEncryption	Unable to encrypt data stream
12337	swErrorMaximumConnections	The maximum number of client connections exceeded
12338	swErrorThreadCreationFailed	Unable to create a new thread for the current process
12339	swErrorInvalidThreadHandle	The specified thread handle is no longer valid
12340	swErrorThreadTerminated	The specified thread has been terminated
12341	swErrorThreadDeadlock	The operation would result in the current thread becoming deadlocked
12342	swErrorInvalidClientMoniker	The specified moniker is not associated with any client session
12343	swErrorClientMonikerExists	The specified moniker has been assigned to another client session
12344	swErrorServerInactive	The specified server is not listening for client connections
12345	swErrorServerSuspended	The specified server is suspended and not accepting client connections

Secure Shell Protocol Control

Establish an interactive terminal session with an SSH server and execute remote commands.

Control Information

Object Name	SshClientCtl.SshClient
File Name	CSTSHX12.OCX
Version	12.0.3024.1286
ProgID	SocketTools.SshClient.12
ClassID	B0BEA64A-6C30-46BB-9ABB-B0B80553050F
Threading Model	Apartment
Help File	CST12CTL.CHM
Dependencies	None
Standards	RFC 4251

Overview

The Secure Shell (SSH) protocol ActiveX control is used to establish a secure connection with a server which provides a virtual terminal session for a user. Its functionality is similar to how character based consoles and serial terminals work, enabling a user to login to the server, execute commands and interact with applications running on the server. The control provides an interface for establishing the connection and handling the standard I/O functions needed by the program.

Standard password and private key authentication methods are supported. The control will automatically select the strongest cipher suite available to both the client and server, providing support for AES-256 encryption and elliptical curve key exchange algorithms like ECDH and Curve25519. The control also supports some legacy algorithms for backwards compatibility with older servers but will only use them if no other options are available. If the server you are connecting with is based on OpenSSH, we recommend using OpenSSH 7.0 or later. Earlier versions of OpenSSH may request the use of encryption algorithms which are no longer considered secure.

The control includes methods which enable a program to easily scan the data stream for specific sequences of characters, making it very simple to write light-weight client interfaces to applications running on the server. It can be combined with the [Terminal Emulation](#) control to provide terminal emulation services for a standard ANSI or DEC-VT220 terminal.

Important: The Secure Shell (SSH) control provides a secure, encrypted alternative to legacy protocols such as Remote Shell (rsh/rcmd), Remote Login (rlogin), and Telnet. Unlike those older protocols, SSH uses strong authentication and end-to-end encryption to protect user credentials, command input, and output data from interception or tampering. SSH is the recommended protocol

for remote command execution and interactive terminal sessions, particularly when connecting over public or untrusted networks. It ensures confidentiality and integrity of data in transit, and is widely supported on modern operating systems and network infrastructure. If you are currently using Telnet or Remote Shell in your applications, you are strongly encouraged to migrate to the Secure Shell API. These older protocols are inherently insecure and should not be used in any context where data security matters.

Requirements

The SocketTools ActiveX Edition components are self-registering controls that are compatible with any programming language that supports the Component Object Model (COM) and the ActiveX control specification. If you are using Visual Basic 6.0, Service Pack 6 (SP6) is required. We recommend installing all available updates for your development tools. Although the Visual Basic 6.0 runtime is supported on Windows 11, the IDE itself is no longer officially supported by Microsoft. Legacy IDEs and compilers may also require elevated (administrator) privileges to run properly.

The ActiveX controls are supported on Windows 7, Windows Server 2008 R2, and later versions of both desktop and server editions of Windows. For Windows 7, Service Pack 1 (SP1) is the minimum requirement. For Windows 8 systems, the 8.1 update must be installed. On ARM-based platforms, the minimum supported version is Windows 10 build 1709.

SocketTools includes components for both 32-bit (x86) and 64-bit (x64) Windows platforms. All modern versions of Windows are 64-bit, but we continue to include 32-bit components for compatibility with legacy development tools such as Visual Basic 6.0. We also provide native ARM64 ActiveX controls for systems running Windows on ARM. Note that 32-bit applications on ARM run using x86 emulation, and Microsoft no longer supports native ARM32 applications.

If you are using VBScript, Visual Basic for Applications (VBA), or another scripting environment on an ARM-based system, be aware that 64-bit hosts will require ARM64 components, while 32-bit hosts will use x86 components under emulation. This includes applications created with Visual Basic 6.0. To reduce deployment complexity and avoid confusion, SocketTools does not include ARM32 ActiveX controls in its standard redistribution packages but they are available on request for legacy or specialized scenarios.

Distribution

When you distribute an application that uses this control, you can either install the file in the same folder as your application executable or as a shared component in the appropriate system folder. If you install the control in the system folder, it is important that you distribute the correct version for the target platform and it must be registered. If you install the control in the same folder as your executable, it is recommended that you use registration-free activation or COM redirection to ensure that the correct version of the control is loaded by the application.

Secure Shell Protocol Control Properties

Property	Description
AutoResolve	Determines if host names and IP addresses are automatically resolved
Blocking	Gets and sets the blocking state of the control
CipherStrength	Return the length of the key used by the encryption algorithm
CodePage	Gets and sets the code page used when reading and writing text
Columns	Gets and sets the number of columns for the virtual terminal session
Command	Gets and sets the command that will be executed on the server
ExitCode	Return the exit code from the command executed on the server
Fingerprint	Returns a string that uniquely identifies the server
HashStrength	Return the length of the message digest that was selected
HostAddress	Gets and sets the IP address of the server
HostName	Gets and sets the name of the server
IsBlocked	Return if the control is blocked performing an operation
IsConnected	Determine if the control is connected to a server
IsInitialized	Determine if the control has been initialized
IsReadable	Return if data can be read from the server without blocking
IsWritable	Return if data can be sent to the server without blocking
KeepAlive	Gets and sets a value which determines if the client session should kept active
LastError	Gets and sets the last error that occurred on the control
LastErrorString	Return a description of the last error to occur
NewLine	Gets and sets the end-of-line character sequences sent to the server
Options	Gets and sets the options that are used in establishing a connection
Password	Gets and sets the password used to authenticate the client session
PrivateKey	Gets and sets the name of the private key file used to authenticate the client session
ProxyHost	Gets and sets the hostname or IP address for the proxy server
ProxyPassword	Gets and sets the password that will be used to authenticate the proxy connection
ProxyPort	Gets and sets the port number for the proxy server
ProxyType	Gets and sets the type of proxy server the connection will be established through
ProxyUser	Gets and sets the user name that will be used to authenticate the proxy connection
RemotePort	Gets and sets the port number for a remote connection
Rows	Gets and sets the number of rows for the virtual terminal session
Secure	Set or return if a connection to the server is secure
SecureCipher	Return the encryption algorithm used to establish the secure connection with the server
SecureHash	Return the message digest selected when establishing the secure connection with the server

SecureKeyExchange	Return the key exchange algorithm used to establish the secure connection with the server
SecureProtocol	Gets and sets the security protocol used to establish the secure connection with the server
Terminal	Gets and sets the terminal type used by the control
ThrowError	Enables or disables error handling by the application
Timeout	Gets and sets the amount of time until a blocking operation fails
Trace	Enable or disable socket function level tracing
TraceFile	Specify the socket function trace output file
TraceFlags	Gets and sets the socket function tracing flags
UserName	Gets and sets the current user name used to authenticate the client session
Version	Return the current version of the control

AutoResolve Property

Determines if host names and IP addresses are automatically resolved.

Syntax

object.AutoResolve [= { True | False }]

Remarks

Setting the **AutoResolve** property determines if the control automatically resolves host names and addresses specified by the **HostName** and **HostAddress** properties. If set to True, setting the **HostName** property will cause the control to automatically determine the corresponding IP address and set the **HostAddress** property accordingly. Likewise, setting the **HostAddress** property will cause the control to determine the host name and set the **HostName** property. Setting the property to False prevents the control from resolving host names until a connection attempt is made.

Note that setting the **HostName** or **HostAddress** property may cause the current thread to block, sometimes for several seconds, until the name or address is resolved. To prevent this behavior, set **AutoResolve** to False.

Data Type

Boolean

See Also

[HostAddress Property](#), [HostName Property](#)

Blocking Property

Gets and sets the blocking state of the control.

Syntax

object.**Blocking** [= { True | False }]

Remarks

Setting the **Blocking** property determines if control actions complete synchronously or asynchronously. If set to True, then each control action, such as sending or receiving data, will return when the operation has completed or timed-out. If set to False, control actions will return immediately. If the operation would result in the control blocking, such as attempting to read data when none has been written, an error is generated. Events such as **OnConnect**, **OnDisconnect**, **OnRead** and **OnWrite** are only fired if the connection is non-blocking.

Data Type

Boolean

See Also

[IsBlocked Property](#), [IsReadable Property](#), [IsWritable Property](#)

CipherStrength Property

Return the length of the key used by the encryption algorithm.

Syntax

object.CipherStrength

Remarks

The **CipherStrength** property returns the number of bits in the key used to encrypt the secure data stream. Common values returned by this property are 128 and 256. A key length of 40-bits or 56-bits is considered to be insecure, and subject to brute force attacks. 128-bit and 256-bit keys are considered secure. If this property returns a value of 0, this means that a secure connection has not been established with the server.

Data Type

Integer (Int32)

See Also

[HashStrength Property](#), [Secure Property](#), [SecureCipher Property](#), [SecureHash Property](#), [SecureKeyExchange Property](#), [SecureProtocol Property](#)

CodePage Property

Gets and sets the code page used when reading and writing text.

Syntax

object.CodePage [= *value*]

Remarks

The **CodePage** property is an integer value which specifies how strings are encoded when data is sent or received. Any valid code page identifier may be specified. Some common values are:

Value	Description
0	Text sent and received using a string should be converted using the ANSI code page for the current locale.
1	Text sent and received using a string should be converted using the system default OEM code page. The OEM code page typically contains characters that are used by console applications and are based on character sets commonly used by MS-DOS. You should not use this code page unless you know the server is sending text which includes OEM characters.
1252	Text sent and received using a string should be converted using the Windows ANSI code page for western European languages. This code page is commonly used by legacy Windows applications for English and some other western languages. It should be noted that while this code page is similar to ISO 8859-1 character encoding, it is not identical.
28591	Text sent and received using a string should be converted using the ISO 8859-1 code page for western European languages. This code page is commonly referred to as Latin-1 and is similar to the Windows 1252 code page.
65000	Data that is sent and received using a string should be converted using UTF-7 encoding. If this code page is specified, data written to the socket will be encoded as UTF-7 encoded Unicode. All data received from the server will be converted from UTF-7. It is not recommended that you use this code page unless you know that the remote host is sending UTF-7 encoded text.
65001	Data that is sent and received using a string should be converted using UTF-8 encoding. If this code page is specified, data written to the socket will be encoded as UTF-8 encoded Unicode. All data received from the server will be converted from UTF-8 to UTF-16 Unicode. Because UTF-8 is backwards compatible with the ASCII character set, it is safe to use this encoding option when sending and receiving ASCII text.

A complete list of available [code page identifiers](#) can be found in Microsoft's documentation for the Win32 API.

All data which is exchanged over a socket is sent and received as 8-bit bytes, typically referred to as "octets" in networking terminology. However, the internal string type used by ActiveX controls are Unicode where each character is represented by 16 bits. To send and receive data using strings, these Unicode strings are converted to a stream of bytes.

By default, strings are converted to an array of bytes using the code page for the current locale, mapping the 16-bit Unicode characters to bytes. Similarly, when reading data from the socket into a

string buffer, the stream of bytes received from the remote host are converted to Unicode before they are returned to your application.

If you are exchanging text with another system and it appears to be corrupted or characters are being replaced with question marks or other symbols, it is likely the system is sending text which is using a different character encoding. Most services use UTF-8 encoding to represent non-ASCII characters and selecting the UTF-8 code page will typically resolve the issue.

Strings are only guaranteed to be safe when sending and receiving text. Using a string data type is not recommended when reading or writing binary data to a socket. If possible, you should always use a byte array as the buffer parameter for the **Read** and **Write** methods whenever you are exchanging binary data.

For backwards compatibility, the control defaults to using the code page for the current locale. This property value directly corresponds to Windows code page identifiers, and will accept any valid code page in addition to the values listed above. Setting this property to an invalid code page will result in an error.

Data Type

Integer (Int32)

See Also

[Read Method](#), [ReadLine Method](#), [Write Method](#), [WriteLine Method](#)

Columns Property

Gets and sets the number of columns for the virtual terminal session.

Syntax

object.Columns [= *columns*]

Remarks

The **Columns** property returns the number of character columns for the virtual display. Setting this property prior to calling the **Connect** method requests that the server create a pseudoterminal with the specified number of columns. This property value is only meaningful for interactive terminal sessions, and is not used when executing a command on the server.

The default value for this property is 80.

Data Type

Integer (Int32)

See Also

[Rows Property](#), [Terminal Property](#), [Connect Method](#)

Command Property

Gets and sets the command that will be executed on the server.

Syntax

object.Command [= *command*]

Remarks

The **Command** property is used to specify a command and its arguments that should be executed on the server. The output of the command will be returned to the application and can be read using the **Read** or **ReadLine** method. If no command is specified, then the control will establish an interactive terminal session instead.

The command and its arguments must follow the conventions used by the SSH server, and the command will execute in the context of the authenticated user. The **ExitCode** property can be used to obtain the numerical exit code of the remote program, if one is available.

Data Type

String

See Also

[ExitCode Property](#), [Connect Method](#), [Execute Method](#), [Read Method](#), [ReadLine Method](#)

ExitCode Property

Return the exit code from the command executed on the server.

Syntax

object.ExitCode

Remarks

The **ExitCode** property returns the numeric exit code for the command that was previously executed on the server. This property value is only meaningful after the command has completed and the connection closed by calling the **Disconnect** method. In most cases, an exit code value of zero indicates success, while any other value indicates an error condition.

Note that the actual value is application dependent and is only meaningful in the context of that particular program. A program may choose to use exit codes in a non-standard way, such as having certain non-zero values indicate success.

The **Reset** method will reset the exit code back to its default value of zero.

Data Type

Integer (Int32)

See Also

[Command Property](#), [Connect Method](#)

Fingerprint Property

Returns a string that uniquely identifies the server.

Syntax

object.Fingerprint

Remarks

The **Fingerprint** property returns a string that consists of a series of hexadecimal values separated by colons. The value is unique to the server, and is an MD5 hash of the RSA host key. An application can use this value to determine if a connection has been established with the server previously by storing the server's host name, IP address and fingerprint in a file, registry key or a database.

Data Type

String

See Also

[Connect Method](#)

HashStrength Property

Return the length of the message digest that was selected.

Syntax

object.HashStrength

Remarks

The **HashStrength** property returns the number of bits used in the message digest (hash) that was selected. Common values returned by this property are 128 and 160. If this property returns a value of 0, this means that a secure connection has not been established with the server.

Data Type

Integer (Int32)

See Also

[CipherStrength Property](#), [Secure Property](#), [SecureCipher Property](#), [SecureHash Property](#), [SecureKeyExchange Property](#), [SecureProtocol Property](#)

HostAddress Property

Gets and sets the IP address of the server.

Syntax

object.HostAddress [= *ipaddress*]

Remarks

The **HostAddress** property can be used to set the IP address for a server that you wish to communicate with. If the address is valid and matches an entry in the host table, the **HostName** property will be changed to match the address.

Data Type

String

See Also

[AutoResolve Property](#), [HostName Property](#)

HostName Property

Gets and sets the name of the server.

Syntax

object.HostName [= *hostname*]

Remarks

The **HostName** property should be set to the name of the server that you wish to communicate with. If the name is found in the host table, the **HostAddress** property is updated to reflect the IP address of the host.

Note that it is legal to assign an IP address to this property, but it is not legal to assign a host name to the **HostAddress** property.

Data Type

String

See Also

[AutoResolve Property](#), [HostAddress Property](#)

IsBlocked Property

Return if the control is blocked performing an operation.

Syntax

object.IsBlocked

Remarks

The **IsBlocked** property returns True if the specified control is blocked performing an operation. Because the Windows Sockets API only permits one blocking operation per thread of execution, this property should be checked before starting any blocking operation.

Note that this property will return True if there is *any* blocking operation being performed by the application, regardless if the specified control is responsible for the blocking operation or not.

Data Type

Boolean

See Also

[Blocking Property](#), [LastError Property](#)

IsConnected Property

Determine if the control is connected to a server.

Syntax

object.**IsConnected**

Remarks

The **IsConnected** read-only property is set to a value of true if the control is connected with a server, otherwise the property has a value of false.

Data Type

Boolean

IsInitialized Property

Determine if the control has been initialized.

Syntax

object.IsInitialized

Remarks

The **IsInitialized** property is used to determine if the current instance of the control has been initialized properly. Normally this is done automatically when the control is loaded, however there are circumstances where the control may not be able to initialize itself. If this property returns **False**, the application must call the **Initialize** method to initialize the control before performing any other operation.

The most common reason that the control may not initialize correctly is that no valid development or runtime license key can be found or the license key that was provided is invalid. It may also indicate a problem with the system configuration or user access rights, such as not being able to load the required networking libraries or not being able to access the system registry.

Data Type

Boolean

See Also

[Initialize Method](#)

IsReadable Property

Return if data can be read from the server without blocking.

Syntax

object.IsReadable

Remarks

The **IsReadable** property returns True if data can be read from the server without blocking. For non-blocking connections, this property can be checked before the application attempts to read the data, preventing an error.

Data Type

Boolean

See Also

[IsConnected Property](#), [Read Method](#), [OnRead Event](#)

IsWritable Property

Return if data can be sent to the server without blocking.

Syntax

object.IsWritable

Remarks

The **IsWritable** property returns True if data can be written without blocking. For non-blocking connections, this property can be checked before the application attempts to send data to the server, preventing an error.

If the **IsWritable** property returns False, this means that the application cannot write to the socket at that time. However, if the property returns True, this does not guarantee that you will be able to send data without an error. The next operation may result in an **stErrorOperationWouldBlock** or **stErrorOperationInProgress** error. The application must treat these errors as recoverable, and should be prepared to retry operations that result in them.

Data Type

Boolean

See Also

[IsReadable Property](#), [SendKey Method](#), [Write Method](#), [OnWrite Event](#)

KeepAlive Property

Gets and sets a value which determines if the client session should kept active.

Syntax

object.**KeepAlive** [= { True | False }]

Remarks

Setting the **KeepAlive** property to a value of true indicates that the client wishes to maintain a long-duration session with the server. It is only necessary to set this property to a value of true if the client session is interactive and the connection must be held open for more than two hours.

ta Type

Boolean

See Also

[Connect Method](#)

LastError Property

Gets and sets the last error that occurred on the control.

Syntax

object.LastError [= *value*]

Remarks

The **LastError** property can be read to determine the last error that occurred for this control. If a value is assigned to this property, it must either be zero to clear the error or a valid error code for the control.

Data Type

Integer (Int32)

See Also

[LastErrorString Property](#), [OnError Event](#)

LastErrorString Property

Return a description of the last error to occur.

Syntax

object.LastErrorString

Remarks

The **LastErrorString** property returns a description of the last error that occurred. This can be used to display a meaningful error message to a user, rather than just the numeric value returned by the **LastError** property.

Data Type

String

See Also

[LastError Property](#), [OnError Event](#)

NewLine Property

Gets and sets the end-of-line character sequences sent to the server.

Syntax

`object.NewLine [= value ]`

Remarks

The **NewLine** property is an integer value that specifies how newlines are sent to the server. It may be one of the following values:

Value	Description
sshNewLineDefault	There are no changes to how data is sent to the server. Any carriage return or linefeed characters that are sent using the Write method will be sent as-is. The WriteLine method will terminate each line of text with a carriage return and linefeed (CRLF) sequence. This is the default line mode that is set when a new connection is established.
sshNewLineCR	A carriage return is used as the end-of-line character. Any data sent using the Write method that contains only a linefeed (LF) character or a carriage return and linefeed (CRLF) sequence to indicate the end-of-line will be replaced by a carriage return (CR) character. The WriteLine method will terminate each line of text with a single carriage return character.
sshNewLineLF	A linefeed is used as the end-of-line character. Any data sent using the Write method that contains only a carriage return (CR) character or a carriage return and linefeed (CRLF) sequence to indicate the end-of-line will be replaced by a linefeed (LF) character. The WriteLine method will terminate each line of text with a single linefeed character.
sshNewLineCRLF	A carriage return and linefeed (CRLF) character sequence is used to indicate the end-of-line. Any data sent using the Write method that contains only a carriage return (CR) or linefeed (LF) will be replaced by a carriage return and linefeed. The WriteLine method will terminate each line of text with a carriage return and linefeed sequence.

When a connection is initially established with the server, it determines what characters are used to indicate the end-of-line and how they are displayed. On UNIX based systems, this is controlled by the settings for the pseudo-terminal that is allocated for the client session, and can be changed using the **stty** command. In most cases, the client line mode can be left at the default. However, in some cases you may need to change the line mode, particularly if you intend to send data from a Windows text file or copied from the clipboard.

Windows uses a carriage return and linefeed (CRLF) sequence to indicate the end-of-line and a UNIX based server may interpret that as multiple newlines. To prevent this, set the **NewLine** property to **sshNewLineCR** and the CRLF sequence in the text will be replaced by a single carriage return.

Data Type

Integer (Int32)

See Also

[Write Method](#), [WriteLine Method](#)

Options Property

Gets and sets the options that are used in establishing a connection.

Syntax

object.Options [= *value*]

Remarks

The **Options** property is an integer value which specifies one or more options. The value specified for this property will be used as the default options when connecting to the server. The property value is created by using a bitwise operator with one or more of the following values:

Value	Description
sshOptionNone	No options specified. A standard terminal session will be established with the default terminal type.
sshOptionKeepAlive	This option specifies the library should attempt to maintain an idle client session for long periods of time. This option is only necessary if you expect that the connection will be held open for more than two hours. This option is the same as setting the KeepAlive property to a value of true.
sshOptionNoPTY	This option specifies that a pseudoterminal (PTY) should not be created for the client session. This option is automatically set if the Command property specifies a command to be executed on the server.
sshOptionNoShell	This option specifies that a command shell should not be used when executing a command on the server.
sshOptionNoAuthRSA	This option specifies that RSA authentication should not be used with SSH-1 connections. This option is ignored with SSH-2 connections and should only be specified if required by the server.
sshOptionNoPwDNul	This option specifies the user password cannot be terminated with a null character. This option is ignored with SSH-2 connections and should only be specified if required by the server.
sshOptionNoRekey	This option specifies the client should never attempt a repeat key exchange with the server. Some SSH servers do not support rekeying the session, and this can cause the client to become non-responsive or abort the connection after being connected for an hour.
sshOptionCompatSID	This compatibility option changes how the session ID is handled during public key authentication with older SSH servers. This option should only be specified when connecting to servers that use OpenSSH 2.2.0 or earlier versions.
sshOptionCompatHMAC	This compatibility option changes how the HMAC authentication codes are generated. This option should only be specified when connecting to servers that use OpenSSH 2.2.0 or earlier

	versions.
sshOptionPreferIPv6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.

Data Type

Integer (Int32)

See Also

[Secure Property](#), [Connect Method](#)

Password Property

Gets and sets the password for the current user.

Syntax

object.Password [= *password*]

Remarks

The **Password** property specifies the password used to authenticate the user. The **UserName** and **Password** properties are used together to provide credentials to the server that will authenticate the client session. This property is used as the default value for the **Connect** method if no password is specified as an argument.

If you are connecting to a server that requires public/private key authentication, your application should set the **PrivateKey** property to the path of the user's private key. In this case, the **Password** property can be used to specify the password required to access the private key. If the private key was created without a password, this property should be set to an empty string.

Data Type

String

See Also

[PrivateKey Property](#), [UserName Property](#), [Connect Method](#)

PrivateKey Property

Gets and sets the private key file used for SSH authentication.

Syntax

object.PrivateKey [= *filename*]

Remarks

The **PrivateKey** property specifies the path to the private key file used to authenticate the user. The private key is used in combination with the value of the **UserName** property to provide credentials to an SSH server. If public/private key authentication is not required by the server, this property is should be set to an empty string.

The **PrivateKey** property value can use environment variables enclosed in percent symbols, and the path to the private key file will be normalized. It is recommended you always use an absolute path to the private key file. If you do not include a path, it will use the current working directory for the process. This can produce inconsistent results because the current working directory for a process is a global value and it can be changed at any time.

The private key file name must resolve to a text file which can be read by the current process. If the file does not exist, or it does not specify a PEM formatted file which contains an RSA or OpenSSH private key, the connection will fail and the last error code will be set to **stErrorInvalidPrivateKey**.

Data Type

String

Example

```
SshClient1.UserName = "username"
SshClient1.PrivateKey = "%USERPROFILE%\.ssh\id_rsa.pem"

nError = SshClient1.Connect("name.server.tld", 22)
If nError > 0 Then
    MsgBox SshClient1.LastErrorString, vbExclamation
    Exit Sub
End If
```

In this example, the path to the private key file will be expanded to an absolute path because the USERPROFILE environment variable defines the home directory for the current user.

See Also

[Password Property](#), [UserName Property](#), [Connect Method](#)

ProxyHost Property

Gets and sets the host name of the proxy server.

Syntax

object.ProxyHost [= *hostname*]

Remarks

The **ProxyHost** property should be set to the name of the proxy server that you want to connect through. This property may be set to either a fully qualified domain name, or an IP address. This property is only used if the **ProxyType** property is set to a non-zero value.

Data Type

String

See Also

[ProxyPassword Property](#), [ProxyPort Property](#), [ProxyType Property](#), [ProxyUser Property](#), [Connect Method](#)

ProxyPassword Property

Gets and sets the proxy server password for the current user.

Syntax

object.ProxyPassword [= *password*]

Remarks

The **ProxyPassword** property specifies the password used to authenticate the user to the proxy server. If a password is not required by the server, this property is ignored.

Data Type

String

See Also

[ProxyHost Property](#), [ProxyPort Property](#), [ProxyType Property](#), [ProxyUser Property](#), [Connect Method](#)

ProxyPort Property

Gets and sets the port number for the proxy server.

Syntax

object.ProxyPort [= *portnumber*]

Remarks

The **ProxyPort** property is used to set the port number that the control will use to establish a connection with the proxy server. A value of zero specifies that the client will connect to the proxy server using the default port for the selected proxy type. If the client is connecting through an HTTP proxy, the connection will be established on port 80 by default. If the client is connecting through a Telnet proxy, the connection will be established on port 23 by default.

Data Type

Integer (Int32)

See Also

[ProxyHost Property](#), [ProxyPassword Property](#), [ProxyType Property](#), [ProxyUser Property](#), [Connect Method](#)

ProxyType Property

Gets and sets the current proxy server type.

Syntax

object.ProxyType = [*proxytype*]

Remarks

The **ProxyType** property specifies the type of proxy server that the client is connecting to. The supported proxy server types are as follows:

Value	Description
sshProxyNone	A direct connection will be established with the server.
sshProxyHttp	Establish a connection through a proxy server using the Hypertext Transfer Protocol.
sshProxyTelnet	Establish a connection through a proxy server using the Telnet protocol.

If the **sshProxyNone** proxy type is specified, then a direct connection is established to the server and the proxy-related properties are ignored. If a port number for the proxy server is not explicitly specified, then the default port number for the proxy server type will be used. If the client is connecting through an HTTP proxy, the connection will be established on port 80 by default. If the client is connecting through a Telnet proxy, the connection will be established on port 23 by default.

Data Type

Integer (Int32)

See Also

[ProxyHost Property](#), [ProxyPassword Property](#), [ProxyPort Property](#), [ProxyUser Property](#), [Secure Property](#), [Connect Method](#)

ProxyUser Property

Gets and sets the current proxy user name.

Syntax

object.ProxyUser [= *username*]

Remarks

The **ProxyUser** property specifies the user that is logging in to the proxy server. If the proxy server does not require user authentication, then this property is ignored.

Data Type

String

See Also

[ProxyHost Property](#), [ProxyPassword Property](#), [ProxyPort Property](#), [ProxyType Property](#), [Connect Method](#)

RemotePort Property

Gets and sets the port number for a remote connection.

Syntax

object.RemotePort [= *portnumber*]

Remarks

The **RemotePort** property is used to set the port number that the control will use to establish a connection with the server.

Data Type

Integer (Int32)

See Also

[HostAddress Property](#), [HostName Property](#)

Rows Property

Gets and sets the number of rows for the virtual terminal session.

Syntax

object.Rows [= *rows*]

Remarks

The **Rows** property returns the number of character rows for the virtual display. Setting this property prior to calling the **Connect** method requests that the server create a pseudoterminal with the specified number of rows. This property value is only meaningful for interactive terminal sessions, and is not used when executing a command on the server.

The default value for this property is 24.

Data Type

Integer (Int32)

See Also

[Columns Property](#), [Terminal Property](#), [Connect Method](#)

Secure Property

Set or return if a connection to the server is secure.

Syntax

object.**Secure** [= { True | False }]

Remarks

The **Secure** property determines if a secure connection is established to the server. The default value for this property is true, and it is included only for compatibility with the other SocketTools components. Because all SSH connections must be secure, attempting to set this property to a value of false will result in an error.

Data Type

Boolean

See Also

[Connect Method](#), [Initialize Method](#)

SecureCipher Property

Return the encryption algorithm used to establish the secure connection with the server.

Syntax

object.SecureCipher

Remarks

The **SecureCipher** property returns an integer value which identifies the algorithm used to encrypt the data stream. This property may return one of the following values:

Value	Description
stCipherNone	No cipher has been selected. This is not a secure connection with the server.
stCipherRC2	The RC2 block cipher was selected. This is a variable key length cipher which supports keys between 40- and 128-bits in length, in 8-bit increments.
stCipherRC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40- and 128-bits in length, in 8-bit increments.
stCipherRC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.
stCipherDES	The DES (Data Encryption Standard) block cipher was selected. This is a fixed key length cipher using 56-bit keys.
stCipherDES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively using a 168-bit key length.
stCipherDESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.
stCipherAES	The Advanced Encryption Standard cipher (also known as the Rijndael cipher) is a fixed block size cipher which use a key size of 128, 192 or 256 bits. This cipher is supported on Windows XP SP3 and later versions of the operating system.
stCipherSkipjack	The Skipjack block cipher was selected. This is a fixed key length cipher, using 80-bit keys.
stCipherBlowfish	The Blowfish block cipher was selected. This is a variable key length cipher up to 448 bits, using a 64-bit block size.

If a secure connection has not been established, this property will return a value of zero.

Data Type

Integer (Int32)

See Also

[CipherStrength Property](#), [HashStrength Property](#), [Secure Property](#), [SecureHash Property](#), [SecureKeyExchange Property](#), [SecureProtocol Property](#)

SecureHash Property

Return the message digest selected when establishing the secure connection with the server.

Syntax

object.SecureHash

Remarks

The **SecureHash** property returns an integer value which identifies the message digest algorithm that was selected when a secure connection is established. This property may return one of the following values:

Value	Description
stHashNone	No message digest algorithm has been selected. This is not a secure connection with the server.
stHashMD5	The MD5 algorithm was selected. This algorithm takes a message of arbitrary length and produces a 128-bit message digest.
stHashSHA	The SHA algorithm was selected. This algorithm produces a 160-bit message digest.

If a secure connection has not been established, this property will return a value of zero.

Data Type

Integer (Int32)

See Also

[CipherStrength Property](#), [HashStrength Property](#), [Secure Property](#), [SecureCipher Property](#), [SecureKeyExchange Property](#), [SecureProtocol Property](#)

SecureKeyExchange Property

Return the key exchange algorithm used to establish the secure connection with the server.

Syntax

`object.SecureKeyExchange`

Remarks

The **SecureKeyExchange** property returns an integer value which identifies the key-exchange algorithm used when establishing a secure connection. This property may return one of the following values:

Value	Description
stKeyExchangeNone	No key exchange algorithm has been selected. This is not a secure connection with the server.
stKeyExchangeRSA	The RSA public key exchange algorithm has been selected.
stKeyExchangeKEA	The KEA public key exchange algorithm has been selected. This is an improved version of the Diffie-Hellman public key algorithm.
stKeyExchangeDH	The Diffie-Hellman public key exchange algorithm has been selected.
stKeyExchangeECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography. This key exchange algorithm is only supported on Windows XP SP3 and later versions of the operating system.

If a secure connection has not been established, this property will return a value of zero.

Data Type

Integer (Int32)

See Also

[CipherStrength Property](#), [HashStrength Property](#), [Secure Property](#), [SecureCipher Property](#), [SecureHash Property](#), [SecureProtocol Property](#)

SecureProtocol Property

Gets and sets the security protocol used to establish the secure connection with the server.

Syntax

object.SecureProtocol [= *protocol*]

Remarks

The **SecureProtocol** property can be used to specify the security protocol to be used when establishing a secure connection with a server. By default, the control will attempt to use either SSH-1 or SSH-2 to establish the connection, with the appropriate protocol automatically selected based on the capabilities of the server. It is recommended that you only change this property value if you fully understand the implications of doing so. Assigning a value to this property will override the default and force the control to attempt to use only the protocol specified. One or more of the following values may be used:

Value	Description
stProtocolNone	No security protocol has been selected. Because all connections to an SSH server are secure, this value indicates that a connection has not been established.
stProtocolSSH1	The Secure Shell 1.0 protocol should be used. This version of the protocol has been deprecated and is no longer widely used. It is not recommended that this version of the protocol be used to establish a connection.
stProtocolSSH2	The Secure Shell 2.0 protocol should be used. This is the most commonly used version of the protocol. It is recommended that this version of the protocol be used unless the server explicitly requires the client to use an earlier version.

Multiple security protocols may be specified by combining them using a bitwise Or operator. After a connection has been established, reading this property will identify the protocol that was selected to establish the connection. Attempting to set this property after a connection has been established will result in an exception being thrown. This property should only be set before calling the **Connect** method.

Data Type

Integer (Int32)

See Also

[CipherStrength Property](#), [HashStrength Property](#), [Secure Property](#), [SecureCipher Property](#), [SecureHash Property](#), [SecureKeyExchange Property](#)

Terminal Property

Gets and sets the terminal type used by the control.

Syntax

object.Terminal [= *termtype*]

Remarks

The **Terminal** property specifies the terminal type of the server for display purposes. On UNIX based systems, the terminal name corresponds to a termcap or terminfo entry as set in the TERM environment variable. On Windows based systems which implement the ssh service, this property may be ignored and the server will assume that the client is capable of displaying ANSI escape sequences. On VMS systems, the terminal name should correspond to the terminal type used with the SET TERMINAL/DEVICE command.

If this property is set to an empty string and no terminal type is specified when the **Connect** method is called, a default terminal type named "unknown" will be used. On most UNIX and VMS systems this defines a terminal which is not capable of cursor positioning using control or escape sequences. This terminal type may not be recognized and an error may be displayed when the user logs in indicating that the terminal type is invalid.

Refer to the documentation for the server system to determine what terminal type names are available to you. Remember that on UNIX systems, the terminal type is case-sensitive. Some of the more common terminal types are:

Terminal Type	Description
ansi	This terminal type is usually available on UNIX based servers. This specifies that the client is capable of displaying standard ANSI escape sequences for cursor control.
dumb	This terminal type typically specifies a terminal display which does not support control or escape sequences for cursor positioning. If you do not want escape sequences embedded in the data stream and the server returns an error if the terminal type is not specified, try using this terminal type.
pcansi	This terminal type is usually available on UNIX based servers. This specifies that the client is using a PC terminal emulator that supports basic ANSI escape sequences for cursor control. This may also enable escape sequences which can set the display colors.
vt100	This terminal type is usually available on UNIX and VMS based servers. On some VMS systems this string may need to be specified as DEC-VT100. This specifies that the client is capable of emulating a DEC VT100 terminal. The VT100 supports many of the same cursor control sequences as an ANSI terminal.
vt220	This terminal type is usually available on UNIX and VMS based servers. On some VMS systems this string may need to be specified as DEC-VT220. This specifies that the client is capable of emulating a DEC VT220 terminal, which is a later version of the VT100.
vt320	This terminal type is usually available on UNIX and VMS based servers. On

	some VMS systems this string may need to be specified as DEC-VT320. This specifies that the client is capable of emulating a DEC VT320 terminal, which is similar to the VT100 and VT220 and provides advanced features such as the ability to set display colors.
xterm	This terminal type is may be available on UNIX based servers which have X Windows installed. This specifies that the client is a using the X Windows xterm emulator which supports standard ANSI escape sequences for cursor control.

Data Type

String

See Also

[Columns Property](#), [Rows Property](#)

ThrowError Property

Enables or disables error handling by the application.

Syntax

object.ThrowError = { True | False }

Remarks

Error handling for methods can be performed using either return codes or exceptions, depending on the value of this property.

If the **ThrowError** property is set to False, methods will return a status value indicating success or failure. Applications should check the return value of each method and use the **LastError** and **LastErrorString** properties to determine the cause of any error.

If the **ThrowError** property is set to True, errors occurring within the control will be raised to the host application as ActiveX exceptions. In addition, the **OnError** event will fire. This allows applications to use language-specific exception handling mechanisms, such as Visual Basic error handling, instead of checking individual return values after each method call.

Even when the **ThrowError** property is set to True, the **LastError** and **LastErrorString** properties will still be updated with information about the most recent error.

If an error occurs while accessing a property value, an exception will be raised regardless of the value of the **ThrowError** property. However, the **OnError** event will not be fired for property access errors.

Data Type

Boolean

Example

The following example handles errors by checking the return code of a method:

```
SshClient1.ThrowError = False
nError = SshClient1.Connect(strHostName)

If nError > 0 Then
    MsgBox SshClient1.LastErrorString, vbExclamation
    Exit Sub
End If
```

The following example handles errors by throwing them to the container:

```
On Error Resume Next: Err.Clear

SshClient1.ThrowError = True
SshClient1.Connect strHostName

If Err.Number <> 0
    MsgBox Err.Description, vbExclamation
    Exit Sub
End If
On Error GoTo 0
```

See Also

[LastError Property](#), [LastErrorString Property](#), [OnError Event](#)

Timeout Property

Gets and sets the amount of time until a blocking operation fails.

Syntax

object.Timeout [= *seconds*]

Remarks

Setting the **Timeout** property specifies the number of seconds until a blocking operation fails and the control returns an error.

Note that the **Timeout** property also determines the amount of time the control will spend attempting to connect to a server. If a connection is not established within the given time period, the connection attempt will fail.

Data Type

Integer (Int32)

Trace Property

Enable or disable network function level logging.

Syntax

`object.Trace` [= { True | False }]

Remarks

The **Trace** property is used to enable or disable the logging of network function calls. When enabled, each function call is logged to a file, including the function parameters, return value and error code if applicable. This facility can be enabled and disabled at run time, and the trace log file can be specified by setting the **TraceFile** property. All function calls that are being logged are appended to the trace file, if it exists. If no log file exists when tracing is enabled, the file is created.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

Data Type

Boolean

See Also

[TraceFile Property](#), [TraceFlags Property](#)

TraceFile Property

Gets and sets the name of the file to use when logging network function calls.

Syntax

`object.TraceFile [= filename ]`

Remarks

The **TraceFile** property is used to specify the name of the file that is created when logging is enabled. If this property is set to an empty string (the default value), then a file named **SocketTools.log** is created in the current user's Documents folder. It is recommended that you always specify a complete path to the log file. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

If the file exists, the output is appended to the file, otherwise the file is created. Since logging is enabled per-process, the log file is shared by all instances of the controls being used. If you create multiple instances of the control, you only need to enable logging for a single instance. Because log files can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "0x". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxx:xxxx:xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, the control is attempting to connect to a system with the IPv4 address 192.0.0.1 on port 1234.

If the log file cannot be created, or the user does not have permission to modify an existing file, the error is silently ignored and no output will be generated.

Data Type

String

See Also

TraceFlags Property

Gets and sets the network function logging flags.

Syntax

object.TraceFlags [= *flags*]

Remarks

The **TraceFlags** property is used to specify the type of information written to the trace file when socket function tracing is enabled. The following values may be used:

Value	Description
dnsTraceInfo	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
dnsTraceError	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
dnsTraceWarning	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
dnsTraceHexDump	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
dnsTraceTruncate	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.

Since logging is enabled per-process, the trace flags are shared by all instances of the control being used. If multiple controls have tracing enabled, the **TraceFlags** property should be set to the same value for each control. Changing the trace flags for any one instance of the control will affect the logging performed for all other instances used by the application.

Warnings are generated when a non-fatal error is returned by a Windows Sockets function. For example, if data is being written through the control and an error indicating that the operation would block is returned, only a warning is logged since the application simply needs to attempt to write the data at a later time.

Data Type

Integer (Int32)

See Also

[Trace Property](#), [TraceFile Property](#)

UserName Property

Gets and sets the current user name.

Syntax

object.UserName [= *username*]

Remarks

The **UserName** property identifies the user that is connecting to the server and is required for authentication purposes. This property is used as the default value for the **Connect** method if no username is specified as an argument.

Data Type

String

See Also

[Password Property](#), [PrivateKey Property](#), [Connect Method](#)

Version Property

Return the current version of the control.

Syntax

object.Version

Remarks

The **Version** property returns the current version of the object. This can be used by an application for validation purposes. The version returned is composed of four numbers, separated by periods. The first number is the major version number, the second number is the minor version number, the third is the build number and the fourth is the revision number.

Data Type

String

Secure Shell Protocol Control Methods

Method	Description
Break	Sends a break signal to the server
Cancel	Cancels the current blocking network operation
Connect	Establish a connection with a server
Control	Send a control message to the server
Disconnect	Terminate the connection with the server
Execute	Execute a command on the server and return the output
Initialize	Initialize the control and validate the runtime license key
Peek	Read data returned by the server, but do not remove it from the receive buffer
Read	Return data read from the server
ReadLine	Read a line of text from the server
Reset	Reset the internal state of the control
Search	Search for a specific character sequence in the data stream
SendKey	Send a key code to the server
Uninitialize	Uninitialize the control and release any system resources that were allocated
Write	Write data to the server
WriteLine	Write a line of text to the server

Break Method

Sends a break signal to the server.

Syntax

object.**Break**

Parameters

None.

Return Value

A value of zero is returned if the break signal was sent successfully. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **Break** method a control message to the server which simulates a break signal on a physical terminal. This is used by some operating systems as an instruction to enter a privileged configuration mode. Note that this is not the same as sending an interrupt character such as Ctrl+C to the server. This control code is ignored for SSH 1.0 sessions.

See Also

[Cancel Method](#), [Control Method](#)

Cancel Method

Cancels the current blocking network operation.

Syntax

object.Cancel

Parameters

None.

Return Value

None.

Remarks

The **Cancel** method cancels any blocking network operation in the current thread. This is typically used inside an event handler, causing the blocking method to return to the caller with an error indicating that the current operation was canceled. This method sets an internal flag that is periodically checked during a blocking operation, such as waiting for more data to arrive. If the current thread is not blocked at the time that this method is called, it will have no effect.

See Also

[Break Method](#), [Control Method](#)

Connect Method

Establish a connection with a server.

Syntax

object.Connect([RemoteHost], [RemotePort], [UserName], [Password], [Timeout], [Options])

Parameters

RemoteHost

A string which specifies the host name or IP address of the server. If this argument is not specified, it defaults to the value of the **HostAddress** property if it is defined. Otherwise, it defaults to the value of the **HostName** property.

RemotePort

A number which specifies the port to connect to on the server. If this argument is not specified, it defaults to the value of the **RemotePort** property. A value of zero indicates that the default port number for this service should be used to establish the connection.

UserName

A string which specifies the user name which will be used to authenticate the client session. This value must specify a valid user name and cannot be an empty string. If this argument is not specified, it defaults to the value of **UserName** property.

Password

A string which specifies the password which will be used to authenticate the client session. If the user does not have a password, this value can be an empty string. If this argument is not specified, it defaults to the value of the **Password** property. If the server requires public/private key authentication, set the **PrivateKey** property to the name of the file containing the private key prior to calling this method.

Timeout

The number of seconds that the client will wait for a response before failing the operation. If this argument is not specified, the value of the **Timeout** property will be used as the default.

Options

A numeric value which specifies one or more options. If this argument is omitted or a value of zero is specified, a default connection will be established. This argument is constructed by using a bitwise operator with any of the following values:

Value	Description
sshOptionNone	No options specified. A standard terminal session will be established with the default terminal type.
sshOptionKeepAlive	This option specifies the library should attempt to maintain an idle client session for long periods of time. This option is only necessary if you expect that the connection will be held open for more than two hours. This option is the same as setting the KeepAlive property to a value of true.
sshOptionNoPTY	This option specifies that a pseudoterminal (PTY) should not be created for the client session. This option is automatically set if the Command property specifies a command to be executed on the server.

sshOptionNoShell	This option specifies that a command shell should not be used when executing a command on the server.
sshOptionPreferIPv6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.

Return Value

A value of zero is returned if the connection was successful. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

See Also

[HostAddress Property](#), [HostName Property](#), [Options Property](#), [Password Property](#), [PrivateKey Property](#), [RemotePort Property](#), [UserName Property](#), [Disconnect Method](#), [OnConnect Event](#)

Control Method

Send a control message to the server.

Syntax

*object.Control(**ControlCode**)*

Parameters

ControlCode

A numeric control code which specifies the control message which should be sent to the server. This may be one of the following values:

Value	Description
sshControlBreak	Sends a control message to the server which simulates a break signal on a physical terminal. This is used by some operating systems as an instruction to enter a privileged configuration mode. Note that this is not the same as sending an interrupt character such as Ctrl+C to the server. This control code is ignored for SSH 1.0 sessions. This is the same as calling the Break method.
sshControlNoop	Sends a control message to the server, but it does not perform any operation. This is typically used by clients to prevent the server from automatically closing a session that has been idle for a long period of time.
sshControlEof	Sends a control message to the server indicating that the client has finished sending data. Note that this option is normally not used with interactive terminal sessions, and should only be used when required by the server.
sshControlPing	Sends a control message to the server which is used to test whether or not the server is responsive to the client. This is typically used by clients to attempt to detect if the connection to the server is still active.
sshControlRekey	Sends a control message to the server requesting that the key exchange be performed again. This control code is ignored for SSH 1.0 sessions.

Return Value

A value of zero is returned if the control code was sent successfully. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **Control** method enables an application to send control messages to the server, which can cause it to take specific actions such as simulate a terminal break or request that the key exchange be performed again. Some control messages are not supported by the SSH 1.0 protocol, in which case the control message is ignored.

See Also

[Break Method](#), [Cancel Method](#)

Disconnect Method

Terminate the connection with a server.

Syntax

object.Disconnect

Parameters

None.

Return Value

A value of zero is returned if the connection was terminated successfully. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

This method terminates the network connection with the server.

See Also

[IsConnected Property](#), [ExitCode Property](#), [Connect Method](#), [OnDisconnect Event](#)

Execute Method

Execute a command on the server and return the output.

Syntax

```
object.Execute( [RemoteHost], [RemotePort], [UserName], [Password], [Command], [Timeout],  
[Options] )
```

Parameters

RemoteHost

A string which specifies the host name or IP address of the server. If this argument is not specified, it defaults to the value of the **HostAddress** property if it is defined. Otherwise, it defaults to the value of the **HostName** property.

RemotePort

A number which specifies the port to connect to on the server. If this argument is not specified, it defaults to the value of the **RemotePort** property. A value of zero indicates that the default port number for this service should be used to establish the connection.

UserName

A string which specifies the user name which will be used to authenticate the client session. If this argument is not specified, it defaults to the value of **UserName** property.

Password

A string which specifies the password which will be used to authenticate the client session. If this argument is not specified, it defaults to the value of the **Password** property.

Command

A string which specifies the command that will be executed on the server. If this argument is not specified, it defaults to the value of the **Command** property.

Timeout

The number of seconds that the client will wait for a response before failing the operation. If this argument is not specified, the value of the **Timeout** property will be used as the default.

Options

A numeric value which specifies one or more options. If this argument is omitted or a value of zero is specified, a default connection will be established. This argument is constructed by using a bitwise operator with any of the following values:

Value	Description
sshOptionNone	No options specified. A standard terminal session will be established with the default terminal type.
sshOptionKeepAlive	This option specifies the library should attempt to maintain an idle client session for long periods of time. This option is only necessary if you expect that the connection will be held open for more than two hours. This option is the same as setting the KeepAlive property to a value of true.
sshOptionNoPTY	This option specifies that a pseudoterminal (PTY) should not be created for the client session. This option is automatically set if the Command property specifies a command to be executed

	on the server.
sshOptionNoShell	This option specifies that a command shell should not be used when executing a command on the server.
sshOptionNoAuthRSA	This option specifies that RSA authentication should not be used with SSH-1 connections. This option is ignored with SSH-2 connections and should only be specified if required by the server.
sshOptionNoPwdNul	This option specifies the user password cannot be terminated with a null character. This option is ignored with SSH-2 connections and should only be specified if required by the server.
sshOptionNoRekey	This option specifies the client should never attempt a repeat key exchange with the server. Some SSH servers do not support rekeying the session, and this can cause the client to become non-responsive or abort the connection after being connected for an hour.
sshOptionCompatSID	This compatibility option changes how the session ID is handled during public key authentication with older SSH servers. This option should only be specified when connecting to servers that use OpenSSH 2.2.0 or earlier versions.
sshOptionCompatHMAC	This compatibility option changes how the HMAC authentication codes are generated. This option should only be specified when connecting to servers that use OpenSSH 2.2.0 or earlier versions.

Return Value

A string that contains the output of the command that was executed on the server. To get the exit code returned by the program, check the value of the **ExitCode** property. If an empty string is returned, this indicates that there was either no data available, or an error has occurred and the **LastError** property will return a non-zero value.

Remarks

This method establishes a network connection with a server and executes the specified command. The output from the command is returned as a string. This method should not be used if the connection to the server must be established through a proxy server. If the connection must be made through a proxy server, then you should set the **Command** property to the specify the command to execute, call the **Connect** method to establish the connection, and then use either the **Read** or **ReadLine** methods to read the output.

When the command output is being read from the server, this method will automatically convert the data to match the end-of-line convention used on the Windows platform. This is useful when executing a command on a UNIX based system where the end-of-line is indicated by a single linefeed, while on Windows it is a carriage-return and linefeed pair. If the output contains embedded nulls or escape sequences, then this conversion will not be performed.

Example

The following example demonstrates how to use the Execute method and check for an error condition:

```
Dim strOutput As String

SshClient1.HostName = strServerName
SshClient1.UserName = strUserName
SshClient1.Password = strPassword
SshClient1.Command = "/bin/ls -l"

strOutput = SshClient1.Execute()

If Len(strOutput) = 0 Then
    If SshClient1.LastError > 0 Then
        MsgBox SshClient1.LastErrorString, vbExclamation
        Exit Sub
    End If
End If
```

See Also

[Command Property](#), [ExitCode Property](#), [LastError Property](#), [Connect Method](#)

Initialize Method

Initialize the control and validate the runtime license key.

Syntax

```
object.Initialize( [LicenseKey] )
```

Parameters

LicenseKey

An optional string value which specifies a runtime license key used to initialize the control. If the license key is omitted or passed as an empty string, a development license must be installed on the local system.

Return Value

A value of zero is returned if the control was initialized successfully. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

This method dynamically loads other system libraries and allocates thread local storage. In most cases, it is not necessary to call this method directly because it is automatically invoked when an instance of the control is created by the container. However, if the control is created dynamically using **CreateObject** or a similar method, this must be the first method that is called before you attempt to modify any property values or invoke other methods. Failure to initialize the control may result in subsequent errors and/or cause an exception to be raised.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the control will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the control was created.

If the control is being used within another DLL, it is important that you do not attempt to create an instance of the control or call the **Initialize** method from within the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is written in C++ and it is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for any static and global C++ objects and has the same restrictions.

Example

```
Set sshClient = CreateObject("SocketTools.SshClient.12")

nError = sshClient.Initialize(strLicenseKey)
If nError > 0 Then
    MsgBox "Unable to initialize SocketTools component"
End
End If
```

[IsInitialized Property](#), [Uninitialize Method](#)

Peek Method

Read data returned by the server, but do not remove it from the receive buffer.

Syntax

*object.Peek(**Buffer**, [**Length**])*

Parameters

Buffer

A buffer that the data will be stored in. If the variable is a **String** then the data will be returned as a string of characters. This is the most appropriate data type to use if the server is sending data that consists of printable characters. If the server is sending binary data, it is recommended that a **Byte** array be used instead. This parameter must be passed by reference.

Length

A numeric value which specifies the number of bytes to read. Its maximum value is $2^{31}-1 = 2147483647$. This argument is required to be present for string data. If a value is specified for this argument for other permissible types of data, and it is less than number of bytes that is determined by the control, then **Length** will override the internally computed value. If the argument is omitted, then the maximum number of bytes to read is determined by the size of the buffer.

Return Value

The number of bytes actually read from the server is returned by this method. If there is no data available to be read, a value of zero is returned. If an error occurs, a value of -1 is returned.

Remarks

The **Peek** method can be used to examine the data that is available to be read from the internal receive buffer. If there is no data in the receive buffer at that time, a value of zero is returned. It should be noted that this differs from the **Read** method, where a return value of zero indicates that there is no more data available to be read and the connection has been closed. The **Peek** method will never cause the client to block, and so may be safely used with asynchronous connections. Note that it is possible for the returned data to contain embedded null characters.

See Also

[IsConnected Property](#), [IsReadable Property](#), [Read Method](#), [ReadLine Method](#), [Search Method](#), [Write Method](#), [OnRead Event](#), [OnWrite Event](#)

Read Method

Return data read from the server.

Syntax

object.Read(*Buffer*, [*Length*])

Parameters

Buffer

A buffer that the data will be stored in. If the variable is a String then the data will be returned as a string of characters. This is the most appropriate data type to use if the server is sending data that consists of printable characters. If the server is sending binary data, it is recommended that a Byte array be used instead.

Length

A numeric value which specifies the number of bytes to read. Its maximum value is $2^{31}-1 = 2147483647$. This argument is required to be present for string data. If a value is specified for this argument for other permissible types of data, and it is less than number of bytes that is determined by the control, then ***Length*** will override the internally computed value. If the argument is omitted, then the maximum number of bytes to read is determined by the size of the buffer.

Return Value

The number of bytes actually read from the server is returned by this method. If an error occurs, a value of -1 is returned.

Remarks

The **Read** method returns data that has been read from the server, up to the number of bytes specified. If no data is available to be read, an error will be generated if the control is non-blocking mode. If the control is in blocking mode, the program will stop until data is returned by the server or the connection is closed. Note that it is possible for the returned data to contain embedded null characters.

See Also

[CodePage Property](#), [IsConnected Property](#), [IsReadable Property](#), [ReadLine Method](#), [Search Method](#), [Write Method](#), [OnRead Event](#)

ReadLine Method

Read up to a line of data from the server and returns it in a string buffer.

Syntax

object.ReadLine(*Buffer*, [*Length*])

Parameters

Buffer

A string that the data will be stored in when the method returns. This parameter must be passed by reference.

Length

An optional parameter that specifies the maximum number of bytes to read. If this argument is omitted, then the control will return up to 4096 characters in the string. If the application expects that a single line of text will exceed this value, then it must be explicitly specified.

Return Value

This method will return true if a line of data has been read. If an error occurs or there is no more data available to read, then the method will return False. It is possible for data to be returned in the string buffer even if the return value is false. Applications should check the length of the string after the method returns to determine if any data was copied into the buffer. For example, if a timeout occurs while the method is waiting for more data to arrive on the socket, it will return zero; however, data may have already been copied into the string buffer prior to the error condition. It is the responsibility of the application to process that data, regardless of the function return value.

Remarks

The **ReadLine** method reads data from the server up to the specified number of bytes or until an end-of-line character sequence is encountered. Unlike the **Read** method which reads arbitrary bytes of data, this function is specifically designed to return a single line of text data in a string variable. When an end-of-line character sequence is encountered, the function will stop and return the data up to that point; the string will not contain the carriage-return or linefeed characters.

There are some limitations when using the **ReadLine** method. The method should only be used to read text, never binary data. In particular, it will discard nulls, linefeed and carriage return control characters. This method will force the thread to block until an end-of-line character sequence is processed, the read operation times out or the server closes its end of the socket connection. If the **Blocking** property is set to False, calling this method will automatically switch the socket into a blocking mode, read the data and then restore the socket to non-blocking mode. If another network operation is attempted while **ReadLine** is blocked waiting for data from the server, an error will occur. It is recommended that this method only be used with blocking connections.

The **Read** and **ReadLine** methods can be intermixed, however be aware that the **Read** method will consume any data that has already been buffered by the **ReadLine** method and this may have unexpected results.

See Also

[CodePage Property](#), [IsReadable Property](#), [Timeout Property](#), [Read Method](#), [Write Method](#), [WriteLine Method](#)

Reset Method

Reset the internal state of the control.

Syntax

object.Reset

Parameters

None.

Return Value

None.

Remarks

The **Reset** method resets the internal state of the control. Property values are initialized to their internal defaults, open network connections will be closed and any handles allocated by the control will be released.

See Also

[Cancel Method](#), [Initialize Method](#), [Uninitialize Method](#)

Search Method

Search for a specific character sequence in the data stream.

Syntax

object.Search(*String*, [*Buffer*], [*Length*], [*Options*])

Parameters

String

A string value which specifies the sequence of characters to search for in the data stream. When the control encounters this sequence, the method will return.

Buffer

An optional string or byte array buffer that will contain the output sent by the server, up to and including the search string character sequence. If this argument is omitted, the control will still search for the character sequence but any output sent by the server will be discarded.

Length

An optional integer value which specifies the maximum number of bytes of data to store in the buffer. If this argument is omitted, no limit will be placed on the amount of output buffered by the control.

Options

An optional integer value which is reserved for future use. This argument should be omitted.

Return Value

This method returns a boolean value. A return value of true indicates that the search string was found in the data stream. A return value of False indicates that the search string was not found in the amount of time specified by the **Timeout** property or that the server closed the connection.

Remarks

The **Search** method searches for a character sequence in the data stream and stops reading when it is found. This is useful when the client wants to automate responses to the server, such as executing a command and processing the output. The function collects the output from the server and stores it in a buffer provided by the caller. When the function returns, the buffer will contain everything sent by the server up to and including the search string.

See Also

[IsReadable Property](#), [Timeout Property](#), [Connect Method](#), [Read Method](#), [ReadLine Method](#)

SendKey Method

Send a key code to the server.

Syntax

object.SendKey(*Key*)

Parameters

Key

A value which specifies the key code to send to the server. This may be a single byte, in which case it is sent to the server as-is. If a numeric value is specified, then this is considered to be an ASCII character value and it is sent to the server as a single byte. The value must be between 1 and 255. If the key code value is 0, then the method returns without sending any data. If the value is greater than 255, an error will be raised. If the **Key** argument is a string, then the method will send that string to the server. An empty string is ignored and the method will return without sending any data. An error will be returned if the string is longer than 128 bytes.

Return Value

This method will return a value of true if the key code was successfully sent to the server. If the key cannot be sent, the method will return False and the **LastError** property will contain the error code that indicates the reason for the failure. This method will also return False if the key code value is zero or an empty string is passed by the caller.

Remarks

The **SendKey** method sends a key code to the server. This method is useful if the application needs to send a single character to the server, as opposed to using the **Write** method which should be used for sending large amounts of data.

The strings sent by the **SendKey** method are typically short escape sequences which are generated by a terminal emulator when the user presses a special key, such as a function key. For example, a DEC VT100 terminal sends the escape sequence <ESC>[M when the user presses the F1 function key. To simulate this, those three bytes could be passed as the **Key** value.

Example

The following example demonstrates how to use the **SendKey** method in conjunction with the **KeyMapped** and **KeyPress** events in the Terminal Emulator control:

```
Private Sub Terminal1_KeyMapped(KeyIndex As Integer, Shift As Integer, KeyString As String)
    SshClient1.SendKey KeyString
End Sub

Private Sub Terminal1_KeyPress(KeyAscii As Integer)
    SshClient1.SendKey KeyAscii
End Sub
```

See Also

[IsWritable Property](#), [Write Method](#), [OnWrite Event](#)

Uninitialize Method

Uninitialize the control and release any system resources that were allocated.

Syntax

object.Uninitialize

Parameters

None.

Return Value

None.

Remarks

The **Uninitialize** method terminates any connection established by the control and resets the internal state of the control. This method is not typically used because any resources that have been allocated by an instance of the control will automatically be released when it is destroyed.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the control will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the control was created. An application should only call the **Uninitialize** method if it has explicitly called the **Initialize** method.

See Also

[Initialize Method](#)

Write Method

Write data to the server.

Syntax

object.Write(*Buffer*, [*Length*])

Parameters

Buffer

A buffer variable that contains the data to be written to the server. If the variable is a **String** type, then the data will be written as a string of characters. This is the most appropriate data type to use if the server expects text data that consists of printable characters. If the server is expecting binary data, it is recommended that a **Byte** array be used instead.

Length

A numeric value which specifies the number of bytes to write. Its maximum value is $2^{31}-1 = 2147483647$. If a value is specified for this argument and it is greater than the actual size of the buffer, then the **Length** argument will be ignored and the entire contents of the buffer will be written. If the argument is omitted, then the maximum number of bytes to write is determined by the size of the buffer.

Return Value

This method returns the number of bytes actually written to the server, or -1 if an error was encountered.

Remarks

The **Write** method sends the data in *buffer* to the server. If the connection is buffered, as is typically the case, the data is copied to the send buffer and control immediately returns to the program. If the control is blocking, the application will wait until the data can be sent. If the control is non-blocking and the write fails because it could not send all of the data to the server, the **OnWrite** event will be fired when the server can accept data again.

See Also

[CodePage Property](#), [IsConnected Property](#), [IsWritable Property](#), [Timeout Property](#), [Read Method](#), [ReadLine Method](#), [SendKey Method](#), [WriteLine Method](#), [OnWrite Event](#)

WriteLine Method

Send a line of text to the server, terminated by a carriage-return and linefeed.

Syntax

object.WriteLine([*Buffer*])

Parameters

Buffer

A string which contains the data that will be sent to the server. The data will always be terminated with a carriage-return and linefeed control character sequence. If this argument is omitted, then a only a carriage-return and linefeed are written to the socket. Note that if the string contains a null character, any data that follows the null character will be discarded.

Return Value

This method returns true if the contents of the string has been written to the server. If an error occurs, the method will return False.

Remarks

The **WriteLine** method writes a line of text to the server and terminates the line with a carriage-return and linefeed control character sequence. Unlike the **Write** method which writes arbitrary bytes of data to the socket, this method is specifically designed to write a single line of text data from a string.

If the *Buffer* string is terminated with a linefeed (LF) or carriage return (CR) character, it will be automatically converted to a standard CRLF end-of-line sequence. Because the string will be sent with a terminating CRLF sequence, the number of characters sent to the remote host will typically be larger than the original string length (reflecting the additional CR and LF characters), unless the string was already terminated with CRLF.

The **WriteLine** method should only be used to send text, never binary data. In particular, the function will discard any data that follows a null character and will append linefeed and carriage return control characters to the data stream. Calling this this method will force the thread to block until the complete line of text has been written, the write operation times out or the server aborts the connection. If this function is called with the **Blocking** property set to False, it will automatically switch the socket into a blocking mode, send the data and then restore the socket to non-blocking mode. If another socket operation is attempted while the **WriteLine** method is blocked sending data to the server, an error will occur. It is recommended that this method only be used with blocking socket connections.

The **Write** and **WriteLine** methods can be safely intermixed.

Secure Shell Protocol Control Events

Event	Description
OnCancel	This event occurs when a blocking operation is canceled
OnConnect	This event occurs when a connection is established
OnDisconnect	This event occurs when a connection is terminated
OnError	This event occurs when a control error occurs
OnRead	This event occurs when data is available to be read
OnTimeout	This event occurs when a blocking operation times out
OnWrite	This event occurs when data can be written to the server

OnCancel Event

The **OnCancel** event is generated when a blocking operation is canceled.

Syntax

Sub *object_OnCancel* ([*Index As Integer*])

Remarks

This event occurs when a blocking operation on the socket, such as sending or receiving data, is canceled with the **Cancel** method. To assist in determining which operation was canceled, consult the **State** property.

See Also

[Cancel Method](#), [OnError Event](#), [OnTimeout Event](#)

OnConnect Event

The **OnConnect** event is generated when a connection is established.

Syntax

Sub *object_OnConnect* ([*Index As Integer*])

Remarks

The **OnConnect** event is generated when a connection is made with a server as a result of a **Connect** method call. This event is only triggered when the **Blocking** property is set to False.

See Also

[Blocking Property](#), [Connect Method](#), [OnDisconnect Event](#), [OnWrite Event](#)

OnDisconnect Event

The **OnDisconnect** event is generated when a connection is terminated.

Syntax

Sub *object_OnDisconnect* ([*Index As Integer*])

Remarks

The **OnDisconnect** event is generated when the connection is terminated by the server. This event is only triggered when the **Blocking** property is set to False.

When the **OnDisconnect** event fires, it is possible that there may still be buffered data available to read from the server. Before disconnecting from the server, the application should attempt to read any remaining data until the **Read** method returns a value of zero, or returns an error indicating that the operation would block.

See Also

[Blocking Property](#), [IsConnected Property](#), [IsReadable Property](#), [Connect Method](#), [Disconnect Method](#), [Read Method](#), [OnConnect Event](#)

OnError Event

The **OnError** event is generated when a control error occurs.

Syntax

Sub *object_OnError* ([*Index As Integer*,] **ByVal** *ErrorCode As Variant*, **ByVal** *Description As Variant*)

Remarks

This event occurs when an error occurs during a control action. Errors not generated by the control itself, such as errors related to the programming language or general component errors, do not trigger this event.

The ***ErrorCode*** argument specifies the last error that has occurred. If the error is network related, the error code values returned by the control correspond to those returned by the standard Windows Sockets library.

The ***Description*** argument is a string that describes the error.

See Also

[LastError Property](#), [LastErrorString Property](#), [ThrowError Property](#)

OnRead Event

The **OnRead** event is generated when data is available to be read.

Syntax

Sub *object_OnRead* ([*Index As Integer*])

Remarks

The **OnRead** event is generated for non-blocking sockets when data is available to be read from the server. Use the **Read** method to read the data. This event is only triggered when the **Blocking** property is set to False.

See Also

[IsReadable Property](#), [Read Method](#), [ReadLine Method](#), [Write Method](#), [WriteLine Method](#), [OnWrite Event](#)

OnTimeout Event

The **OnTimeout** event is fired when a blocking operation times out.

Syntax

Sub *object_OnTimeout* ([*Index As Integer*])

Remarks

The **OnTimeout** event is generated when a blocking socket operation, such as sending or receiving data, times out. To determine which operation was in progress when the timeout occurred, consult the **State** property. This event is only triggered when the **Blocking** property is set to True.

See Also

[Timeout Property](#), [OnCancel Event](#)

OnWrite Event

The **OnWrite** event is generated when data can be written to the server.

Syntax

Sub *object_OnWrite* ([*Index As Integer*])

Remarks

The **OnWrite** event is generated for non-blocking sockets when data can be written to the server after a previous attempt failed because it would cause the control to block. This event is only triggered when the **Blocking** property is set to False.

[IsWritable Property](#), [Read Method](#), [ReadLine Method](#), [SendKey Method](#), [Write Method](#), [WriteLine Method](#), [OnConnect Event](#), [OnRead Event](#)

Telnet Protocol Control

Establish an interactive terminal session with a server.

Reference

- [Properties](#)
- [Methods](#)
- [Events](#)
- [Error Codes](#)

Control Information

Object Name	TelnetClientCtl.TelnetClient
File Name	CSTNTX12.OCX
Version	12.0.3024.1286
ProgID	SocketTools.TelnetClient.12
ClassID	B400A760-1864-4B79-B29A-F4F1A882C466
Threading Model	Apartment
Help File	CST12CTL.CHM
Dependencies	None
Standards	RFC 854

Overview

The Telnet protocol is used to establish a connection with a server which provides a virtual terminal session for a user. Its functionality is similar to how character based consoles and serial terminals work, enabling a user to login to the server, execute commands and interact with applications running on the server. The control provides an interface for establishing the connection, negotiating certain options (such as whether characters will be echoed back to the client) and handling the standard I/O functions needed by the program.

The control also provides methods that enable a program to easily scan the data stream for specific sequences of characters, making it very simple to write light-weight client interfaces to applications running on the server. This control can be combined with the SocketTools Terminal control to provide complete terminal emulation services for a standard ANSI or DEC-VT220 terminal.

Caution: The Telnet protocol transmits all data, including login credentials, in plaintext and does not provide any inherent encryption. While this control supports optional TLS connections for Telnet, secure Telnet servers are rare in practice. This protocol is still supported for compatibility with legacy systems, but it is strongly recommended that you use secure protocols such as SSH whenever possible, especially when connecting over public or untrusted networks. To establish a secure connection to the server using the Secure Shell (SSH) protocol, use the [SshClient](#) control.

Requirements

The SocketTools ActiveX Edition components are self-registering controls that are compatible with any programming language that supports the Component Object Model (COM) and the ActiveX control specification. If you are using Visual Basic 6.0, Service Pack 6 (SP6) is required. We recommend

installing all available updates for your development tools. Although the Visual Basic 6.0 runtime is supported on Windows 11, the IDE itself is no longer officially supported by Microsoft. Legacy IDEs and compilers may also require elevated (administrator) privileges to run properly.

The ActiveX controls are supported on Windows 7, Windows Server 2008 R2, and later versions of both desktop and server editions of Windows. For Windows 7, Service Pack 1 (SP1) is the minimum requirement. For Windows 8 systems, the 8.1 update must be installed. On ARM-based platforms, the minimum supported version is Windows 10 build 1709.

SocketTools includes components for both 32-bit (x86) and 64-bit (x64) Windows platforms. All modern versions of Windows are 64-bit, but we continue to include 32-bit components for compatibility with legacy development tools such as Visual Basic 6.0. We also provide native ARM64 ActiveX controls for systems running Windows on ARM. Note that 32-bit applications on ARM run using x86 emulation, and Microsoft no longer supports native ARM32 applications.

If you are using VBScript, Visual Basic for Applications (VBA), or another scripting environment on an ARM-based system, be aware that 64-bit hosts will require ARM64 components, while 32-bit hosts will use x86 components under emulation. This includes applications created with Visual Basic 6.0. To reduce deployment complexity and avoid confusion, SocketTools does not include ARM32 ActiveX controls in its standard redistribution packages but they are available on request for legacy or specialized scenarios.

Distribution

When you distribute an application that uses this control, you can either install the file in the same folder as your application executable or as a shared component in the appropriate system folder. If you install the control in the system folder, it is important that you distribute the correct version for the target platform and it must be registered. If you install the control in the same folder as your executable, it is recommended that you use registration-free activation or COM redirection to ensure that the correct version of the control is loaded by the application.

Telnet Protocol Control Properties

Property	Description
AutoResolve	Determines if host names and IP addresses are automatically resolved
Binary	Enable or disable binary input and output
Blocking	Gets and sets the blocking state of the control
CertificateExpires	Return the date and time that the server certificate expires
CertificateIssued	Return the date and time that the server certificate was issued
CertificateIssuer	Returns information about the organization that issued the server certificate
CertificateName	Gets and sets the common name for the client certificate
CertificatePassword	Gets and sets the password associated with the client certificate
CertificateStatus	Return the status of the server certificate
CertificateStore	Gets and sets the name of the client certificate store or file
CertificateSubject	Returns information about the organization to which the server certificate was issued
CertificateUser	Gets and sets the user that owns the client certificate
CipherStrength	Return the length of the key used by the encryption algorithm
CodePage	Gets and sets the code page used when reading and writing text
HashStrength	Return the length of the message digest that was selected
HostAddress	Gets and sets the IP address of the server
HostName	Gets and sets the name of the server
IsBlocked	Return if the control is blocked performing an operation
IsConnected	Determine if the control is connected to a server
IsInitialized	Determine if the control has been initialized
IsReadable	Return if data can be read from the server without blocking
IsWritable	Return if data can be sent to the server without blocking
LastError	Gets and sets the last error that occurred on the control
LastErrorString	Return a description of the last error to occur
LocalEcho	Enable or disable the echoing of characters by the server
Options	Gets and sets the options that are used in establishing a connection
Password	Gets and sets the password for the current user
RemotePort	Gets and sets the port number for a remote connection
Secure	Set or return if a connection to the server is secure
SecureCipher	Return the encryption algorithm used to establish the secure connection with the server
SecureHash	Return the message digest selected when establishing the secure connection with the server
SecureKeyExchange	Return the key exchange algorithm used to establish the secure connection with the server
SecureProtocol	Gets and sets the security protocol used to establish the secure connection with the server

Terminal	Gets and sets the terminal type used by the control
ThrowError	Enables or disables error handling by the application
Timeout	Gets and sets the amount of time until a blocking operation fails
Trace	Enable or disable socket function level tracing
TraceFile	Specify the socket function trace output file
TraceFlags	Gets and sets the socket function tracing flags
UserName	Gets and sets the current user name
Version	Return the current version of the control

AutoResolve Property

Determines if host names and IP addresses are automatically resolved.

Syntax

object.AutoResolve [= { True | False }]

Remarks

Setting the **AutoResolve** property determines if the control automatically resolves host names and addresses specified by the **HostName** and **HostAddress** properties. If set to True, setting the **HostName** property will cause the control to automatically determine the corresponding IP address and set the **HostAddress** property accordingly. Likewise, setting the **HostAddress** property will cause the control to determine the host name and set the **HostName** property. Setting the property to False prevents the control from resolving host names until a connection attempt is made.

Note that setting the **HostName** or **HostAddress** property may cause the current thread to block, sometimes for several seconds, until the name or address is resolved. To prevent this behavior, set **AutoResolve** to False.

Data Type

Boolean

See Also

[HostAddress Property](#), [HostName Property](#)

Binary Property

Enable or disable binary input and output.

Syntax

object.**Binary** [= { True | False }]]

Remarks

The **Binary** property enables or disables the exchange of binary data between the client and server. If set to False, all characters have the high-bit stripped off and single linefeed characters are automatically converted to carriage-return/linefeed sequences. The default value is True, which specifies that data is to be received unchanged from the server.

Data Type

Boolean

See Also

[LocalEcho Property](#)

Blocking Property

Gets and sets the blocking state of the control.

Syntax

object.**Blocking** [= { True | False }]

Remarks

Setting the **Blocking** property determines if control actions complete synchronously or asynchronously. If set to True, then each control action, such as sending or receiving data, will return when the operation has completed or timed-out. If set to False, control actions will return immediately. If the operation would result in the control blocking, such as attempting to read data when none has been written, an error is generated. Events such as **OnConnect**, **OnDisconnect**, **OnRead** and **OnWrite** are only fired if the connection is non-blocking.

Data Type

Boolean

See Also

[IsBlocked Property](#), [IsReadable Property](#), [IsWritable Property](#)

CertificateExpires Property

Return the date and time that the server certificate expires.

Syntax

object.CertificateExpires

Remarks

The **CertificateExpires** property returns the date and time that the server certificate expires. This property will return an empty string if a secure connection has not been established with the server.

Data Type

String

See Also

[CertificateIssued Property](#), [CertificateIssuer Property](#), [CertificateStatus Property](#), [CertificateSubject Property](#), [Secure Property](#)

CertificateIssued Property

Return the date and time that the server certificate was issued.

Syntax

object.CertificateIssued

Remarks

The **CertificateIssued** property returns the date and time that the server certificate was issued. This property will return an empty string if a secure connection has not been established with the server.

Data Type

String

See Also

[CertificateExpires Property](#), [CertificateIssuer Property](#), [CertificateStatus Property](#), [CertificateSubject Property](#), [Secure Property](#)

CertificateIssuer Property

Returns information about the organization that issued the server certificate.

Syntax

object.CertificateIssuer

Remarks

The **CertificateIssuer** property returns a string that contains information about the organization that issued the server certificate. The string value is a comma separated list of tagged name and value pairs. In the nomenclature of the X.500 standard, each of these pairs are called a relative distinguished name (RDN), and when concatenated together, forms the issuer's distinguished name (DN). For example:

C=US, O="RSA Data Security, Inc.", OU=Secure Server Certification Authority

To obtain a specific value, such as the name of the issuer or the issuer's country, the application must parse the string returned by this property. Some of the common tokens used in the distinguished name are:

Name	Description
C	The ISO standard two character country code
S	The name of the state or province
L	The name of the city or locality
O	The name of the company or organization
OU	The name of the department or organizational unit
CN	The common name; with X.509 certificates, this is the domain name of the site the certificate was issued for

This property will return an empty string if a secure connection has not been established with the server.

Data Type

String

Example

The following example demonstrates how to extract the value of a relative distinguished name token:

```
Function GetCertNameValue(ByVal strValue As String, ByVal strFieldName As String)
As String
    Dim strFieldValue As String
    Dim cchValue As Integer, cchFieldName As Integer
    Dim nOffset As Integer

    GetCertNameValue = ""
    cchValue = Len(strValue)
    cchFieldName = Len(strFieldName)

    If cchValue = 0 Or cchFieldName = 0 Then
        Exit Function
    End If
```

```

nOffset = InStr(strValue, strFieldName & "=")

If nOffset > 0 Then
    '
    ' If the field name was found in the string, then
    ' remove everything to the left of the token from
    ' the string
    '
    strFieldValue = Right(strValue, cchValue - (nOffset + cchFieldName))

    '
    ' If the value is quoted, then strip off the leading
    ' quote and look for the ending quote in the string;
    ' otherwise look for the comma that marks the end of
    ' the field name/value pair
    '
    If Left(strFieldValue, 1) = Chr(34) Then
        strFieldValue = Right(strFieldValue, Len(strFieldValue) - 1)
        nOffset = InStr(strFieldValue, Chr(34))
    Else
        nOffset = InStr(strFieldValue, ",")
    End If

    '
    ' If the offset is 0, then the name/value pair is
    ' the last token in the string; otherwise, remove
    ' everything to the right of that position
    '
    If nOffset > 0 Then
        strFieldValue = Left(strFieldValue, nOffset - 1)
    End If

    GetCertNameValue = strFieldValue
End If

```

End Function

This function could then be used to return the name of the company who issued the server certificate:

```

Dim strIssuer As String
Dim strCompanyName As String

strIssuer = TelnetClient1.CertificateIssuer
If Len(strIssuer) = 0 Then
    MsgBox "A secure connection has not been established"
Else
    strCompanyName = GetCertNameValue(strIssuer, "O")
    MsgBox "This certificate was issued by " & strCompanyName
End If

```

See Also

[CertificateExpires Property](#), [CertificateIssued Property](#), [CertificateStatus Property](#), [CertificateSubject Property](#), [Secure Property](#)

CertificateName Property

Gets and sets the common name for the client certificate.

Syntax

object.CertificateName [= *name*]

Remarks

This property sets the common name or friendly name of the certificate that should be used to establish the connection with the server. It is only required that you set this property value if the server requires a client certificate for authentication. If this property is not set, a client certificate will not be provided to the server. If a certificate name is specified, the certificate must have a private key associated with it, otherwise the connection attempt will fail because the control will be unable to create a security context for the session.

Certificates may be installed and viewed on the local system using the Certificate Manager that is included with the Windows operating system. For more information, refer to the documentation for the Microsoft Management Console.

Data Type

String

See Also

[CertificateStore Property](#), [Secure Property](#)

CertificatePassword Property

Gets and sets the password associated with the client certificate.

Syntax

object.CertificatePassword [= *password*]

Remarks

This property sets the password that should be used to access a certificate in the specified certificate store. It is only required when the **CertificateStore** property specifies a file that contains a certificate and private key in PKCS #12 format.

Data Type

String

See Also

[CertificateName Property](#), [CertificateStore Property](#), [Secure Property](#)

CertificateStatus Property

Return the status of the server certificate.

Syntax

`object.CertificateStatus`

Remarks

The **CertificateStatus** property returns an integer value which identifies the status of the server certificate. This property may return one of the following values:

Value	Description
stCertificateNone	No certificate information is available. A secure connection was not established with the server.
stCertificateValid	The certificate is valid.
stCertificateNoMatch	The certificate is valid, however the domain name specified in the certificate does not match the domain name of the site that the client has connected to. This is typically the case if the HostAddress property is used rather than the HostName property. It is recommended that the client examine the CertificateSubject property to determine the domain name of the site that the certificate was issued for.
stCertificateExpired	The certificate has expired and is no longer valid. The client can examine the CertificateExpires property to determine when the certificate expired.
stCertificateRevoked	The certificate has been revoked and is no longer valid. It is recommended that the client application immediately terminate the connection if this status is returned.
stCertificateUntrusted	The certificate has not been issued by a trusted authority, or the certificate is not trusted on the local host. It is recommended that the client application immediately terminate the connection if this status is returned.
stCertificateInvalid	The certificate is invalid. This typically indicates that the internal structure of the certificate is damaged. It is recommended that the client application immediately terminate the connection if this status is returned.

This property value should be checked after the connection to the server has completed, but prior to beginning a transaction. If a secure connection has not been established, this property will return a value of zero.

Data Type

Integer (Int32)

Example

The following example establishes a secure connection to a server:

```
TelnetClient1.HostName = strHostName
```

```
TelnetClient1.Secure = True

nError = TelnetClient1.Connect()
If nError > 0 Then
    MsgBox "Unable to connect to server " & strHostName, vbExclamation
    Exit Sub
End If

If TelnetClient1.CertificateStatus <> stCertificateValid Then
    nResult = MsgBox("The server certificate could not be validated" & vbCrLf & _
        "Are you sure you wish to continue?", vbYesNo)

    If nResult = vbNo Then
        TelnetClient1.Disconnect
        Exit Sub
    End If
End If

TelnetClient1.Disconnect
```

See Also

[CertificateExpires Property](#), [CertificateIssued Property](#), [CertificateIssuer Property](#), [CertificateSubject Property](#), [Secure Property](#)

CertificateStore Property

Gets and sets the name of the client certificate store or file.

Syntax

object.CertificateStore [= *store*]

Remarks

This property sets the name of the certificate store that contains the client certificate that should be used when establishing a secure connection with the server. The certificate may either be stored in the registry or in a file. If the certificate is stored in the registry, then this property should be set to one of the following predefined values:

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. If a certificate store is not specified, this is the default value that is used.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

In most cases the client certificate will be installed in the user's personal certificate store, and therefore it is not necessary to set this property value because that is the default location that will be used to search for the certificate. This property is only used if the **CertificateName** property is also set to a valid certificate name.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU" for the current user, or "HKLM" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, it will default to the certificate store for the current user.

This property may also be used to specify a file that contains the client certificate. In this case, the property should specify the full path to the file and must contain both the certificate and private key in PKCS #12 format. If the file is protected by a password, the **CertificatePassword** property must also be set to specify the password.

Data Type

String

See Also

[CertificateName Property](#), [CertificatePassword Property](#), [Secure Property](#)

CertificateSubject Property

Returns information about the organization that the server certificate was issued to.

Syntax

`object.CertificateSubject`

Remarks

The **CertificateSubject** property returns a string that contains information about the organization that the server certificate was issued for. The string value is a comma separated list of tagged name and value pairs. In the nomenclature of the X.500 standard, each of these pairs are called a relative distinguished name (RDN), and when concatenated together, forms the subject's distinguished name (DN). For example:

C=US, O="RSA Data Security, Inc.", OU=Secure Server Certification Authority

To obtain a specific value, such as the name of the subject's company or country, the application must parse the string returned by this property. Some of the common tokens used in the distinguished name are:

Name	Description
C	The ISO standard two character country code
S	The name of the state or province
L	The name of the city or locality
O	The name of the company or organization
OU	The name of the department or organizational unit
CN	The common name; with X.509 certificates, this is the domain name of the site the certificate was issued for

This property will return an empty string if a secure connection has not been established with the server.

Data Type

String

Example

The following example demonstrates how to extract the value of a relative distinguished name token:

```
Function GetCertNameValue(ByVal strValue As String, ByVal strFieldName As String)
As String
    Dim strFieldValue As String
    Dim cchValue As Integer, cchFieldName As Integer
    Dim nOffset As Integer

    GetCertNameValue = ""
    cchValue = Len(strValue)
    cchFieldName = Len(strFieldName)

    If cchValue = 0 Or cchFieldName = 0 Then
        Exit Function
    End If
```

```

nOffset = InStr(strValue, strFieldName & "=")

If nOffset > 0 Then
    '
    ' If the field name was found in the string, then
    ' remove everything to the left of the token from
    ' the string
    '
    strFieldValue = Right(strValue, cchValue - (nOffset + cchFieldName))

    '
    ' If the value is quoted, then strip off the leading
    ' quote and look for the ending quote in the string;
    ' otherwise look for the comma that marks the end of
    ' the field name/value pair
    '

    If Left(strFieldValue, 1) = Chr(34) Then
        strFieldValue = Right(strFieldValue, Len(strFieldValue) - 1)
        nOffset = InStr(strFieldValue, Chr(34))
    Else
        nOffset = InStr(strFieldValue, ",")
    End If

    '
    ' If the offset is 0, then the name/value pair is
    ' the last token in the string; otherwise, remove
    ' everything to the right of that position
    '

    If nOffset > 0 Then
        strFieldValue = Left(strFieldValue, nOffset - 1)
    End If

    GetCertNameValue = strFieldValue
End If

```

End Function

This function could then be used to return the domain name that the server certificate was issued for:

```

Dim strSubject As String
Dim strDomainName As String

strSubject = TelnetClient1.CertificateSubject
If Len(strSubject) = 0 Then
    MsgBox "A secure connection has not been established"
Else
    strDomainName = GetCertNameValue(strSubject, "CN")
    MsgBox "This certificate was issued for " & strDomainName
End If

```

See Also

[CertificateExpires Property](#), [CertificateIssued Property](#), [CertificateIssuer Property](#), [CertificateStatus Property](#), [Secure Property](#)

CertificateUser Property

Gets and sets the user that owns the client certificate.

Syntax

object.CertificateUser [= *username*]

Remarks

This property sets the name of the user that owns the client certificate that will be used to establish a secure connection with the server. If this property is not set, the certificate store for the current user will be used when searching for the certificate. If this property is used to specify another user, the process must have the appropriate permission to access the registry location that contains the client certificate. On Windows Vista and later versions of the operating system, this requires that the process run with elevated privileges.

Data Type

String

See Also

[CertificateName Property](#), [CertificateStore Property](#), [Secure Property](#)

CipherStrength Property

Return the length of the key used by the encryption algorithm.

Syntax

object.CipherStrength

Remarks

The **CipherStrength** property returns the number of bits in the key used to encrypt the secure data stream. Common values returned by this property are 128 and 256. A key length of 40-bits or 56-bits is considered to be insecure, and subject to brute force attacks. 128-bit and 256-bit keys are considered secure. If this property returns a value of 0, this means that a secure connection has not been established with the server.

Data Type

Integer (Int32)

See Also

[HashStrength Property](#), [Secure Property](#), [SecureCipher Property](#), [SecureHash Property](#), [SecureKeyExchange Property](#), [SecureProtocol Property](#)

CodePage Property

Gets and sets the code page used when reading and writing text.

Syntax

object.CodePage [= *value*]

Remarks

The **CodePage** property is an integer value which specifies how strings are encoded when data is sent or received. Any valid code page identifier may be specified. Some common values are:

Value	Description
0	Text sent and received using a string should be converted using the ANSI code page for the current locale.
1	Text sent and received using a string should be converted using the system default OEM code page. The OEM code page typically contains characters that are used by console applications and are based on character sets commonly used by MS-DOS. You should not use this code page unless you know the server is sending text which includes OEM characters.
1252	Text sent and received using a string should be converted using the Windows ANSI code page for western European languages. This code page is commonly used by legacy Windows applications for English and some other western languages. It should be noted that while this code page is similar to ISO 8859-1 character encoding, it is not identical.
28591	Text sent and received using a string should be converted using the ISO 8859-1 code page for western European languages. This code page is commonly referred to as Latin-1 and is similar to the Windows 1252 code page.
65000	Data that is sent and received using a string should be converted using UTF-7 encoding. If this code page is specified, data written to the socket will be encoded as UTF-7 encoded Unicode. All data received from the server will be converted from UTF-7. It is not recommended that you use this code page unless you know that the remote host is sending UTF-7 encoded text.
65001	Data that is sent and received using a string should be converted using UTF-8 encoding. If this code page is specified, data written to the socket will be encoded as UTF-8 encoded Unicode. All data received from the server will be converted from UTF-8 to UTF-16 Unicode. Because UTF-8 is backwards compatible with the ASCII character set, it is safe to use this encoding option when sending and receiving ASCII text.

A complete list of available [code page identifiers](#) can be found in Microsoft's documentation for the Win32 API.

All data which is exchanged over a socket is sent and received as 8-bit bytes, typically referred to as "octets" in networking terminology. However, the internal string type used by ActiveX controls are Unicode where each character is represented by 16 bits. To send and receive data using strings, these Unicode strings are converted to a stream of bytes.

By default, strings are converted to an array of bytes using the code page for the current locale, mapping the 16-bit Unicode characters to bytes. Similarly, when reading data from the socket into a

string buffer, the stream of bytes received from the remote host are converted to Unicode before they are returned to your application.

If you are exchanging text with another system and it appears to be corrupted or characters are being replaced with question marks or other symbols, it is likely the system is sending text which is using a different character encoding. Most services use UTF-8 encoding to represent non-ASCII characters and selecting the UTF-8 code page will typically resolve the issue.

Strings are only guaranteed to be safe when sending and receiving text. Using a string data type is not recommended when reading or writing binary data to a socket. If possible, you should always use a byte array as the buffer parameter for the **Read** and **Write** methods whenever you are exchanging binary data.

For backwards compatibility, the control defaults to using the code page for the current locale. This property value directly corresponds to Windows code page identifiers, and will accept any valid code page in addition to the values listed above. Setting this property to an invalid code page will result in an error.

Data Type

Integer (Int32)

See Also

[Read Method](#), [ReadLine Method](#), [Write Method](#), [WriteLine Method](#)

HashStrength Property

Return the length of the message digest that was selected.

Syntax

object.HashStrength

Remarks

The **HashStrength** property returns the number of bits used in the message digest (hash) that was selected. Common values returned by this property are 128 and 160. If this property returns a value of 0, this means that a secure connection has not been established with the server.

Data Type

Integer (Int32)

See Also

[CipherStrength Property](#), [Secure Property](#), [SecureCipher Property](#), [SecureHash Property](#), [SecureKeyExchange Property](#), [SecureProtocol Property](#)

HostAddress Property

Gets and sets the IP address of the server.

Syntax

object.HostAddress [= *ipaddress*]

Remarks

The **HostAddress** property can be used to set the IP address for a server that you wish to communicate with. If the address is valid and matches an entry in the host table, the **HostName** property will be changed to match the address.

Data Type

String

See Also

[AutoResolve Property](#), [HostName Property](#)

HostName Property

Gets and sets the name of the server.

Syntax

object.HostName [= *hostname*]

Remarks

The **HostName** property should be set to the name of the server that you wish to communicate with. If the name is found in the host table, the **HostAddress** property is updated to reflect the IP address of the host.

Note that it is legal to assign an IP address to this property, but it is not legal to assign a host name to the **HostAddress** property.

Data Type

String

See Also

[AutoResolve Property](#), [HostAddress Property](#)

IsBlocked Property

Return if the control is blocked performing an operation.

Syntax

object.IsBlocked

Remarks

The **IsBlocked** property returns True if the specified control is blocked performing an operation. Because the Windows Sockets API only permits one blocking operation per thread of execution, this property should be checked before starting any blocking operation.

Note that this property will return True if there is *any* blocking operation being performed by the application, regardless if the specified control is responsible for the blocking operation or not.

Data Type

Boolean

See Also

[Blocking Property](#), [LastError Property](#)

IsConnected Property

Determine if the control is connected to a server.

Syntax

object.**IsConnected**

Remarks

The **IsConnected** read-only property is set to a value of true if the control is connected with a server, otherwise the property has a value of false.

Data Type

Boolean

IsInitialized Property

Determine if the control has been initialized.

Syntax

object.IsInitialized

Remarks

The **IsInitialized** property is used to determine if the current instance of the control has been initialized properly. Normally this is done automatically when the control is loaded, however there are circumstances where the control may not be able to initialize itself. If this property returns **False**, the application must call the **Initialize** method to initialize the control before performing any other operation.

The most common reason that the control may not initialize correctly is that no valid development or runtime license key can be found or the license key that was provided is invalid. It may also indicate a problem with the system configuration or user access rights, such as not being able to load the required networking libraries or not being able to access the system registry.

Data Type

Boolean

See Also

[Initialize Method](#)

IsReadable Property

Return if data can be read from the server without blocking.

Syntax

object.IsReadable

Remarks

The **IsReadable** property returns True if data can be read from the server without blocking. For non-blocking connections, this property can be checked before the application attempts to read the data, preventing an error.

Data Type

Boolean

See Also

[IsConnected Property](#), [Read Method](#), [OnRead Event](#)

IsWritable Property

Return if data can be sent to the server without blocking.

Syntax

object.IsWritable

Remarks

The **IsWritable** property returns True if data can be written without blocking. For non-blocking connections, this property can be checked before the application attempts to send data to the server, preventing an error.

If the **IsWritable** property returns False, this means that the application cannot write to the socket at that time. However, if the property returns True, this does not guarantee that you will be able to send data without an error. The next operation may result in an **stErrorOperationWouldBlock** or **stErrorOperationInProgress** error. The application must treat these errors as recoverable, and should be prepared to retry operations that result in them.

Data Type

Boolean

See Also

[IsReadable Property](#), [SendKey Method](#), [Write Method](#), [OnWrite Event](#)

LastError Property

Gets and sets the last error that occurred on the control.

Syntax

object.LastError [= *value*]

Remarks

The **LastError** property can be read to determine the last error that occurred for this control. If a value is assigned to this property, it must either be zero to clear the error or a valid error code for the control.

Data Type

Integer (Int32)

See Also

[LastErrorString Property](#), [OnError Event](#)

LastErrorString Property

Return a description of the last error to occur.

Syntax

object.LastErrorString

Remarks

The **LastErrorString** property returns a description of the last error that occurred. This can be used to display a meaningful error message to a user, rather than just the numeric value returned by the **LastError** property.

Data Type

String

See Also

[LastError Property](#), [OnError Event](#)

LocalEcho Property

Enable or disable the echoing of characters by the server.

Syntax

object.**LocalEcho** [= { True | False }]]

Remarks

The **LocalEcho** property enables or disables the echoing of characters by the server. If set to True, the server will be instructed to not echo characters, making the client responsible for displaying user input. The default value for this property is False, specifying that the server should echo user input back to the client.

Data Type

Boolean

See Also

[Binary Property](#)

Options Property

Gets and sets the options that are used in establishing a connection.

Syntax

object.Options [= *value*]

Remarks

The **Options** property is an integer value which specifies one or more options. The value specified for this property will be used as the default options when connecting to the server. The property value is created by using a bitwise operator with one or more of the following values:

Value	Description
telnetOptionNone	No additional options are specified when establishing a connection with the server. A standard, non-secure connection will be used.
telnetOptionTunnel	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
telnetOptionTrustedSite	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
telnetOptionSecure	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using the TLS protocol.
telnetOptionSecureExplicit	This option specifies the client should attempt to establish a secure connection with the server using the START_TLS option. The client initiates a standard connection with the server, then requests a secure connection during the option negotiation process.
telnetOptionSecureFallback	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
telnetOptionPreferIPv6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.

Data Type

Integer (Int32)

See Also

[Secure Property](#), [Connect Method](#)

Password Property

Gets and sets the password for the current user.

Syntax

object.Password [= *password*]

Remarks

The **Password** property specifies the password used to authenticate the user. This property is used as the default value for the **Login** method if no password is specified as an argument.

Data Type

String

See Also

[UserName Property](#), [Connect Method](#), [Login Method](#)

RemotePort Property

Gets and sets the port number for a remote connection.

Syntax

object.RemotePort [= *portnumber*]

Remarks

The **RemotePort** property is used to set the port number that the control will use to establish a connection with the server.

Data Type

Integer (Int32)

See Also

[HostAddress Property](#), [HostName Property](#)

Secure Property

Set or return if a connection to the server is secure.

Syntax

object.Secure [= { True | False }]

Remarks

The **Secure** property determines if a secure connection is established to the server. The default value for this property is False, which specifies that a standard connection to the server is used. To establish a secure connection, the application must set this property value to True prior to calling the **Connect** method. Once the connection has been established, the client may request files or submit queries to the server as with standard connections.

It is strongly recommended that any application that sets this property True use error handling to trap an errors that may occur. If the control is unable to initialize the security libraries, or otherwise cannot create a secure session for the client, an error will be generated when this property value is set.

Data Type

Boolean

Example

The following example establishes a secure connection to a server:

```
TelnetClient1.HostName = strHostName
TelnetClient1.RemotePort = 992
TelnetClient1.Secure = True

nError = TelnetClient1.Connect()
If nError > 0 Then
    MsgBox "Unable to connect to server " & strHostName, vbExclamation
    Exit Sub
End If

If TelnetClient1.CertificateStatus <> stCertificateValid Then
    nResult = MsgBox("The server certificate could not be validated" & vbCrLf & _
        "Are you sure you wish to continue?", vbYesNo)

    If nResult = vbNo Then
        TelnetClient1.Disconnect
        Exit Sub
    End If
End If
```

See Also

[CertificateStatus Property](#), [Connect Method](#)

SecureCipher Property

Return the encryption algorithm used to establish the secure connection with the server.

Syntax

object.SecureCipher

Remarks

The **SecureCipher** property returns an integer value which identifies the algorithm used to encrypt the data stream. This property may return one of the following values:

Value	Description
stCipherNone	No cipher has been selected. This is not a secure connection with the server.
stCipherRC2	The RC2 block cipher was selected. This is a variable key length cipher which supports keys between 40- and 128-bits in length, in 8-bit increments.
stCipherRC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40- and 128-bits in length, in 8-bit increments.
stCipherRC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.
stCipherDES	The DES (Data Encryption Standard) block cipher was selected. This is a fixed key length cipher using 56-bit keys.
stCipherDES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively using a 168-bit key length.
stCipherDESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.
stCipherAES	The Advanced Encryption Standard cipher (also known as the Rijndael cipher) is a fixed block size cipher which use a key size of 128, 192 or 256 bits. This cipher is supported on Windows XP SP3 and later versions of the operating system.
stCipherSkipjack	The Skipjack block cipher was selected. This is a fixed key length cipher, using 80-bit keys.
stCipherBlowfish	The Blowfish block cipher was selected. This is a variable key length cipher up to 448 bits, using a 64-bit block size.

If a secure connection has not been established, this property will return a value of zero.

Data Type

Integer (Int32)

See Also

[CipherStrength Property](#), [HashStrength Property](#), [Secure Property](#), [SecureHash Property](#), [SecureKeyExchange Property](#), [SecureProtocol Property](#)

SecureHash Property

Return the message digest selected when establishing the secure connection with the server.

Syntax

object.SecureHash

Remarks

The **SecureHash** property returns an integer value which identifies the message digest algorithm that was selected when a secure connection is established. This property may return one of the following values:

Value	Description
stHashMD5	The MD5 algorithm was selected. This algorithm has been deprecated and is no longer considered to be cryptographically secure.
stHashSHA1	The SHA-1 algorithm was selected. This algorithm has been deprecated and is no longer considered to be cryptographically secure.
stHashSHA256	The SHA-256 algorithm has been selected.
stHashSHA384	The SHA-384 algorithm has been selected.
stHashSHA512	The SHA-512 algorithm has been selected.

If a secure connection has not been established, this property will return a value of zero.

Data Type

Integer (Int32)

See Also

[CipherStrength Property](#), [HashStrength Property](#), [Secure Property](#), [SecureCipher Property](#), [SecureKeyExchange Property](#), [SecureProtocol Property](#)

SecureKeyExchange Property

Return the key exchange algorithm used to establish the secure connection with the server.

Syntax

object.SecureKeyExchange

Remarks

The **SecureKeyExchange** property returns an integer value which identifies the key-exchange algorithm used when establishing a secure connection. This property may return one of the following values:

Value	Description
stKeyExchangeNone	No key exchange algorithm has been selected. This is not a secure connection with the server.
stKeyExchangeRSA	The RSA public key exchange algorithm has been selected.
stKeyExchangeKEA	The KEA public key exchange algorithm has been selected. This is an improved version of the Diffie-Hellman public key algorithm.
stKeyExchangeDH	The Diffie-Hellman public key exchange algorithm has been selected.
stKeyExchangeECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography. This key exchange algorithm is only supported on Windows XP SP3 and later versions of the operating system.

If a secure connection has not been established, this property will return a value of zero.

Data Type

Integer (Int32)

See Also

[CipherStrength Property](#), [HashStrength Property](#), [Secure Property](#), [SecureCipher Property](#), [SecureHash Property](#), [SecureProtocol Property](#)

SecureProtocol Property

Gets and sets the security protocol used to establish the secure connection with the server.

Syntax

object.SecureProtocol [= *protocol*]

Remarks

The **SecureProtocol** property can be used to specify the security protocol to be used when establishing a secure connection with a server. By default, the control will attempt to use TLS 1.3 to establish the connection. If TLS 1.3 is not supported, TLS 1.2 will be used. The appropriate protocol is automatically selected based on the capabilities of both the client and server.

It is recommended that you only change this property value if you fully understand the implications of doing so. Assigning a value to this property will override the default and force the control to attempt to use only the protocol specified. One or more of the following values may be used:

Value	Description
stProtocolNone	No security protocol has been selected. A secure connection has not been established.
stProtocolTLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
stProtocolTLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
stProtocolTLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
stProtocolTLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

Multiple security protocols may be specified by combining them using a bitwise Or operator. After a connection has been established, reading this property will identify the protocol that was selected to establish the connection. Attempting to set this property after a connection has been established will result in an exception being thrown. This property should only be set after setting the **Secure** property to True and before calling the **Connect** method.

Data Type

Integer (Int32)

See Also

[CipherStrength Property](#), [HashStrength Property](#), [Secure Property](#), [SecureCipher Property](#), [SecureHash Property](#), [SecureKeyExchange Property](#)

Terminal Property

Gets and sets the terminal type used by the control.

Syntax

object.Terminal [= *termtype*]

Remarks

The **Terminal** property specifies the terminal type of the server for display purposes. On UNIX based systems, the terminal name corresponds to a termcap or terminfo entry as set in the TERM environment variable. On Windows based systems which implement the telnet service, this property may be ignored and the server will assume that the client is capable of displaying ANSI escape sequences. On VMS systems, the terminal name should correspond to the terminal type used with the SET TERMINAL/DEVICE command.

If this property is set to an empty string and no terminal type is specified when the **Connect** method is called, a default terminal type named "unknown" will be used. On most UNIX and VMS systems this defines a terminal which is not capable of cursor positioning using control or escape sequences. This terminal type may not be recognized and an error may be displayed when the user logs in indicating that the terminal type is invalid.

Refer to the documentation for the server system to determine what terminal type names are available to you. Remember that on UNIX systems, the terminal type is case-sensitive. Some of the more common terminal types are:

Terminal Type	Description
ansi	This terminal type is usually available on UNIX based servers. This specifies that the client is capable of displaying standard ANSI escape sequences for cursor control.
dumb	This terminal type typically specifies a terminal display which does not support control or escape sequences for cursor positioning. If you do not want escape sequences embedded in the data stream and the server returns an error if the terminal type is not specified, try using this terminal type.
pcansi	This terminal type is usually available on UNIX based servers. This specifies that the client is using a PC terminal emulator that supports basic ANSI escape sequences for cursor control. This may also enable escape sequences which can set the display colors.
vt100	This terminal type is usually available on UNIX and VMS based servers. On some VMS systems this string may need to be specified as DEC-VT100. This specifies that the client is capable of emulating a DEC VT100 terminal. The VT100 supports many of the same cursor control sequences as an ANSI terminal.
vt220	This terminal type is usually available on UNIX and VMS based servers. On some VMS systems this string may need to be specified as DEC-VT220. This specifies that the client is capable of emulating a DEC VT220 terminal, which is a later version of the VT100.
vt320	This terminal type is usually available on UNIX and VMS based servers. On

	some VMS systems this string may need to be specified as DEC-VT320. This specifies that the client is capable of emulating a DEC VT320 terminal, which is similar to the VT100 and VT220 and provides advanced features such as the ability to set display colors.
xterm	This terminal type is may be available on UNIX based servers which have X Windows installed. This specifies that the client is a using the X Windows xterm emulator which supports standard ANSI escape sequences for cursor control.

Data Type

String

See Also

[Login Method](#)

ThrowError Property

Enables or disables error handling by the application.

Syntax

object.ThrowError = { True | False }

Remarks

Error handling for methods can be performed using either return codes or exceptions, depending on the value of this property.

If the **ThrowError** property is set to False, methods will return a status value indicating success or failure. Applications should check the return value of each method and use the **LastError** and **LastErrorString** properties to determine the cause of any error.

If the **ThrowError** property is set to True, errors occurring within the control will be raised to the host application as ActiveX exceptions. In addition, the **OnError** event will fire. This allows applications to use language-specific exception handling mechanisms, such as Visual Basic error handling, instead of checking individual return values after each method call.

Even when the **ThrowError** property is set to True, the **LastError** and **LastErrorString** properties will still be updated with information about the most recent error.

If an error occurs while accessing a property value, an exception will be raised regardless of the value of the **ThrowError** property. However, the **OnError** event will not be fired for property access errors.

Data Type

Boolean

Example

The following example handles errors by checking the return code of a method:

```
TelnetClient1.ThrowError = False
nError = TelnetClient1.Connect(strHostName)

If nError > 0 Then
    MsgBox TelnetClient1.LastErrorString, vbExclamation
    Exit Sub
End If
```

The following example handles errors by throwing them to the container:

```
On Error Resume Next: Err.Clear

TelnetClient1.ThrowError = True
TelnetClient1.Connect strHostName

If Err.Number <> 0
    MsgBox Err.Description, vbExclamation
    Exit Sub
End If
On Error GoTo 0
```

See Also

[LastError Property](#), [LastErrorString Property](#), [OnError Event](#)

Timeout Property

Gets and sets the amount of time until a blocking operation fails.

Syntax

object.Timeout [= *seconds*]

Remarks

Setting the **Timeout** property specifies the number of seconds until a blocking operation fails and the control returns an error.

Note that the **Timeout** property also determines the amount of time the control will spend attempting to connect to a server. If a connection is not established within the given time period, the connection attempt will fail.

Data Type

Integer (Int32)

Trace Property

Enable or disable network function level logging.

Syntax

`object.Trace [= { True | False } ]`

Remarks

The **Trace** property is used to enable or disable the logging of network function calls. When enabled, each function call is logged to a file, including the function parameters, return value and error code if applicable. This facility can be enabled and disabled at run time, and the trace log file can be specified by setting the **TraceFile** property. All function calls that are being logged are appended to the trace file, if it exists. If no log file exists when tracing is enabled, the file is created.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

Data Type

Boolean

See Also

[TraceFile Property](#), [TraceFlags Property](#)

TraceFile Property

Gets and sets the name of the file to use when logging network function calls.

Syntax

`object.TraceFile [= filename ]`

Remarks

The **TraceFile** property is used to specify the name of the file that is created when logging is enabled. If this property is set to an empty string (the default value), then a file named **SocketTools.log** is created in the current user's Documents folder. It is recommended that you always specify a complete path to the log file. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

If the file exists, the output is appended to the file, otherwise the file is created. Since logging is enabled per-process, the log file is shared by all instances of the controls being used. If you create multiple instances of the control, you only need to enable logging for a single instance. Because log files can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "0x". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxx:xxxx:xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, the control is attempting to connect to a system with the IPv4 address 192.0.0.1 on port 1234.

If the log file cannot be created, or the user does not have permission to modify an existing file, the error is silently ignored and no output will be generated.

Data Type

String

See Also

TraceFlags Property

Gets and sets the network function logging flags.

Syntax

object.TraceFlags [= *flags*]

Remarks

The **TraceFlags** property is used to specify the type of information written to the trace file when socket function tracing is enabled. The following values may be used:

Value	Description
dnsTraceInfo	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
dnsTraceError	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
dnsTraceWarning	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
dnsTraceHexDump	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
dnsTraceTruncate	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.

Since logging is enabled per-process, the trace flags are shared by all instances of the control being used. If multiple controls have tracing enabled, the **TraceFlags** property should be set to the same value for each control. Changing the trace flags for any one instance of the control will affect the logging performed for all other instances used by the application.

Warnings are generated when a non-fatal error is returned by a Windows Sockets function. For example, if data is being written through the control and an error indicating that the operation would block is returned, only a warning is logged since the application simply needs to attempt to write the data at a later time.

Data Type

Integer (Int32)

See Also

[Trace Property](#), [TraceFile Property](#)

UserName Property

Gets and sets the current user name.

Syntax

object.UserName [= *username*]

Remarks

The **UserName** property specifies the user that is logging in to the server, and is required for authentication purposes. This property is used as the default value for the **Login** method if no password is specified as an argument.

Data Type

String

See Also

[Password Property](#), [Connect Method](#), [Login Method](#)

Version Property

Return the current version of the control.

Syntax

object.Version

Remarks

The **Version** property returns the current version of the object. This can be used by an application for validation purposes. The version returned is composed of four numbers, separated by periods. The first number is the major version number, the second number is the minor version number, the third is the build number and the fourth is the revision number.

Data Type

String

Telnet Protocol Control Methods

Method	Description
Abort	Aborts the current session and terminates the connection
Break	Sends a break signal to the server
Cancel	Cancels the current blocking network operation
Connect	Establish a connection with a server
Disconnect	Terminate the connection with a server
Initialize	Initialize the control and validate the runtime license key
Login	Authenticate the user and log them in to the current session
Read	Return data read from the server
ReadLine	Read a line of text from the server and return it in a string buffer
Reset	Reset the internal state of the control
Search	Search for a specific character sequence in the data stream
SendKey	Send a key code to the server
Uninitialize	Uninitialize the control and release any system resources that were allocated
Write	Write data to the server
WriteLine	Write a line of text to the server

Abort Method

Aborts the current session and terminates the connection.

Syntax

object.Abort

Parameters

None.

Return Value

A value of zero is returned if the break signal was sent successfully. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **Abort** method sends an abort sequence to the server and the connection to the server is terminated. Once this method returns, the client is no longer connected to the server. If a program is currently executing on the server at the time this function is called, that program may be terminated as a result of the session being aborted. Applications should normally call the **Disconnect** method to gracefully disconnect from the server and should only use this function when the connection must be aborted immediately.

See Also

[Break Method](#), [Cancel Method](#)

Break Method

Sends a break signal to the server.

Syntax

object.**Break**

Parameters

None.

Return Value

A value of zero is returned if the break signal was sent successfully. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **Break** method sends a signal to the server which may terminate an application that is currently running. The actual response to the break signal depends on the application.

See Also

[Abort Method](#), [Cancel Method](#)

Cancel Method

Cancels the current blocking network operation.

Syntax

object.Cancel

Parameters

None.

Return Value

None.

Remarks

The **Cancel** method cancels any blocking network operation in the current thread. This is typically used inside an event handler, causing the blocking method to return to the caller with an error indicating that the current operation was canceled. This method sets an internal flag that is periodically checked during a blocking operation, such as waiting for more data to arrive. If the current thread is not blocked at the time that this method is called, it will have no effect.

See Also

[Abort Method](#), [Break Method](#)

Connect Method

Establish a connection with a server.

Syntax

object.Connect([RemoteHost], [RemotePort], [Timeout], [Options])

Parameters

RemoteHost

A string which specifies the host name or IP address of the server. If this argument is not specified, it defaults to the value of the **HostAddress** property if it is defined. Otherwise, it defaults to the value of the **HostName** property.

RemotePort

A number which specifies the port to connect to on the server. If this argument is not specified, it defaults to the value of the **RemotePort** property. A value of zero indicates that the default port number for this service should be used to establish the connection.

Timeout

The number of seconds that the client will wait for a response before failing the operation. If this argument is not specified, the value of the **Timeout** property will be used as the default.

Options

A numeric value which specifies one or more options. If this argument is omitted or a value of zero is specified, a default connection will be established. This argument is constructed by using a bitwise operator with any of the following values:

Value	Description
telnetOptionNone	No additional options are specified when establishing a connection with the server. A standard, non-secure connection will be used.
telnetOptionTunnel	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
telnetOptionTrustedSite	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
telnetOptionSecure	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using the TLS protocol.
telnetOptionSecureExplicit	This option specifies the client should attempt to establish a secure connection with the server using the START_TLS option. The client initiates a standard connection with the server, then requests a secure connection during the option negotiation process.

telnetOptionSecureFallback	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
telnetOptionPreferIPv6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.

Return Value

A value of zero is returned if the connection was successful. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

Caution: The Telnet protocol transmits all data, including login credentials, in plaintext and does not provide any inherent encryption. While this control supports optional TLS connections for Telnet, secure Telnet servers are rare in practice. This protocol is still supported for compatibility with legacy systems, but it is strongly recommended that you use secure protocols such as SSH whenever possible, especially when connecting over public or untrusted networks. To establish a secure connection to the server using the Secure Shell (SSH) protocol, use the [SshClient](#) control.

See Also

[HostAddress Property](#), [HostName Property](#), [Options Property](#), [RemotePort Property](#), [Disconnect Method](#), [OnConnect Event](#)

Disconnect Method

Terminate the connection with a server.

Syntax

object.Disconnect

Parameters

None.

Return Value

A value of zero is returned if the connection was terminated successfully. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

This method terminates the network connection with the server.

See Also

[IsConnected Property](#), [Connect Method](#), [OnDisconnect Event](#)

Initialize Method

Initialize the control and validate the runtime license key.

Syntax

```
object.Initialize( [LicenseKey] )
```

Parameters

LicenseKey

An optional string value which specifies a runtime license key used to initialize the control. If the license key is omitted or passed as an empty string, a development license must be installed on the local system.

Return Value

A value of zero is returned if the control was initialized successfully. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

This method dynamically loads other system libraries and allocates thread local storage. In most cases, it is not necessary to call this method directly because it is automatically invoked when an instance of the control is created by the container. However, if the control is created dynamically using **CreateObject** or a similar method, this must be the first method that is called before you attempt to modify any property values or invoke other methods. Failure to initialize the control may result in subsequent errors and/or cause an exception to be raised.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the control will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the control was created.

If the control is being used within another DLL, it is important that you do not attempt to create an instance of the control or call the **Initialize** method from within the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is written in C++ and it is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for any static and global C++ objects and has the same restrictions.

Example

```
Set telnetClient = CreateObject("SocketTools.TelnetClient.12")

nError = telnetClient.Initialize(strLicenseKey)
If nError > 0 Then
    MsgBox "Unable to initialize SocketTools component"
End
End If
```

See Also

[IsInitialized Property](#), [Uninitialize Method](#)

Login Method

Authenticate the user and log them in to the current session.

Syntax

`object.Login( [UserName], [Password] )`

Parameters

UserName

An optional string argument which specifies the username which should be used to authenticate the client session. If this argument is omitted, the value of the **UserName** property will be used.

Password

An optional string argument which specifies the password which should be used to authenticate the client session. If this argument is omitted, the value of the **Password** property will be used.

Return Value

A value of zero is returned if the operation was successful, otherwise a non-zero error code is returned which indicates the cause of the failure.

Remarks

Caution: The Telnet protocol transmits all data, including login credentials, in plaintext and does not provide any inherent encryption. While this control supports optional TLS connections for Telnet, secure Telnet servers are rare in practice. This protocol is still supported for compatibility with legacy systems, but it is strongly recommended that you use secure protocols such as SSH whenever possible, especially when connecting over public or untrusted networks. To establish a secure connection to the server using the Secure Shell (SSH) protocol, use the [SshClient](#) control.

This method is specifically designed to work with most UNIX based servers, and may work with other servers that use a similar login process. The method works by scanning the data stream for a username prompt and then replying with the specified username. If that is successful, it will then scan for a password prompt and provide the specified password. If no recognized prompt is found, or if the server responds with an error indicating that the username or password is invalid, the method will fail.

If the **Login** method succeeds, the next call to the **Read** method by the client will return any welcome message to the user. This is typically followed by a command prompt where the user can enter commands to be executed on the server. The data sent by the server during the login process is discarded and not available when the function returns. If the client requires this information, use the **Search** method to automate the login process instead.

Because the **Login** method is designed for UNIX based systems, it may not work with servers running on other operating system platforms such as Windows or VMS. In this case, applications should use the **Search** method to search for the appropriate login prompts in the data stream.

See Also

[Connect Method](#), [Disconnect Method](#), [Read Method](#), [Search Method](#)

Read Method

Return data read from the server.

Syntax

object.Read(*Buffer*, [*Length*])

Parameters

Buffer

A buffer that the data will be stored in. If the variable is a **String** then the data will be returned as a string of characters. This is the most appropriate data type to use if the server is sending data that consists of printable characters. If the server is sending binary data, a **Byte** array should be used instead. This parameter must be passed by reference.

Length

A numeric value which specifies the number of bytes to read. Its maximum value is $2^{31}-1 = 2147483647$. This argument is required to be present for string data. If a value is specified for this argument for other permissible types of data, and it is less than number of bytes that is determined by the control, then **Length** will override the internally computed value. If the argument is omitted, then the maximum number of bytes to read is determined by the size of the buffer.

Return Value

The number of bytes actually read from the server is returned by this method. If an error occurs, a value of -1 is returned.

Remarks

The **Read** method returns data that has been read from the server, up to the number of bytes specified. If no data is available to be read, an error will be generated if the control is non-blocking mode. If the control is in blocking mode, the program will stop until data is returned by the server or the connection is closed.

If the data contains binary characters, particularly non-printable control characters and embedded nulls, you should always provide a **Byte** array to the **Read** method. When you provide a **String** variable as the buffer, the control will process the data as text. Binary characters may be interpreted as 8-bit ANSI encoding and embedded null characters will corrupt the data. Reading the data into a byte array ensures that you receive the data exactly as it was sent by the server.

See Also

[CodePage Property](#), [IsConnected Property](#), [IsReadable Property](#), [Search Method](#), [Write Method](#), [OnRead Event](#), [OnWrite Event](#)

ReadLine Method

Read up to a line of data from the server and returns it in a string buffer.

Syntax

object.ReadLine(*Buffer*, [*Length*])

Parameters

Buffer

A string that the data will be stored in when the method returns. This parameter must be passed by reference.

Length

An optional parameter that specifies the maximum number of bytes to read. If this argument is omitted, then the control will return up to 4096 characters in the string. If the application expects that a single line of text will exceed this value, then it must be explicitly specified.

Return Value

This method will return true if a line of data has been read. If an error occurs or there is no more data available to read, then the method will return False. It is possible for data to be returned in the string buffer even if the return value is false. Applications should check the length of the string after the method returns to determine if any data was copied into the buffer. For example, if a timeout occurs while the method is waiting for more data to arrive on the socket, it will return zero; however, data may have already been copied into the string buffer prior to the error condition. It is the responsibility of the application to process that data, regardless of the function return value.

Remarks

The **ReadLine** method reads data from the server up to the specified number of bytes or until an end-of-line character sequence is encountered. Unlike the **Read** method which reads arbitrary bytes of data, this function is specifically designed to return a single line of text data in a string variable. When an end-of-line character sequence is encountered, the function will stop and return the data up to that point; the string will not contain the carriage-return or linefeed characters.

There are some limitations when using the **ReadLine** method. The method should only be used to read text, never binary data. In particular, it will discard nulls, linefeed and carriage return control characters. This method will force the thread to block until an end-of-line character sequence is processed, the read operation times out or the server closes its end of the socket connection. If the **Blocking** property is set to False, calling this method will automatically switch the socket into a blocking mode, read the data and then restore the socket to non-blocking mode. If another network operation is attempted while **ReadLine** is blocked waiting for data from the server, an error will occur. It is recommended that this method only be used with blocking connections.

The **Read** and **ReadLine** methods can be intermixed, however be aware that the **Read** method will consume any data that has already been buffered by the **ReadLine** method and this may have unexpected results.

See Also

[CodePage Property](#), [IsReadable Property](#), [Timeout Property](#), [Read Method](#), [Write Method](#), [WriteLine Method](#)

Reset Method

Reset the internal state of the control.

Syntax

object.Reset

Parameters

None.

Return Value

None.

Remarks

The **Reset** method resets the internal state of the control. Property values are initialized to their internal defaults, open network connections will be closed and any handles allocated by the control will be released.

See Also

[Cancel Method](#), [Initialize Method](#), [Uninitialize Method](#)

Search Method

Search for a specific character sequence in the data stream.

Syntax

object.Search(*String*, [*Buffer*], [*Length*], [*Options*])

Parameters

String

A string argument which specifies the sequence of characters to search for in the data stream. When the control encounters this sequence, the method will return.

Buffer

An optional string or byte array buffer that will contain the output sent by the server, up to and including the search string character sequence. If this argument is omitted, the control will still search for the character sequence but any output sent by the server will be discarded.

Length

An optional integer value which specifies the maximum number of bytes of data to store in the buffer. If this argument is omitted, no limit will be placed on the amount of output buffered by the control.

Options

An optional integer argument which is reserved for future use. This argument should be omitted.

Return Value

This method returns a boolean value. A return value of true indicates that the search string was found in the data stream. A return value of False indicates that the search string was not found in the amount of time specified by the **Timeout** property or that the server closed the connection.

Remarks

The **Search** method searches for a character sequence in the data stream and stops reading when it is found. This is useful when the client wants to automate responses to the server, such as executing a command and processing the output. The function collects the output from the server and stores it in a buffer provided by the caller. When the function returns, the buffer will contain everything sent by the server up to and including the search string.

See Also

[IsReadable Property](#), [Timeout Property](#), [Connect Method](#), [Login Method](#), [Read Method](#)

SendKey Method

Send a key code to the server.

Syntax

object.SendKey(*Key*)

Parameters

Key

A value which specifies the key code to send to the server. This may be a single byte, in which case it is sent to the server as-is. If a numeric value is specified, then this is considered to be an ASCII character value and it is sent to the server as a single byte. The value must be between 1 and 255. If the key code value is 0, then the method returns without sending any data. If the value is greater than 255, an error will be raised. If the **Key** argument is a string, then the method will send that string to the server. An empty string is ignored and the method will return without sending any data. An error will be returned if the string is longer than 128 bytes.

Return Value

This method will return a value of true if the key code was successfully sent to the server. If the key cannot be sent, the method will return False and the **LastError** property will contain the error code that indicates the reason for the failure. This method will also return False if the key code value is zero or an empty string is passed by the caller.

Remarks

The **SendKey** method sends a key code to the server. This method is useful if the application needs to send a single character to the server, as opposed to using the **Write** method which should be used for sending large amounts of data.

The strings sent by the **SendKey** method are typically short escape sequences which are generated by a terminal emulator when the user presses a special key, such as a function key. For example, a DEC VT100 terminal sends the escape sequence <ESC>[M when the user presses the F1 function key. To simulate this, those three bytes could be passed as the **Key** value.

Example

The following example demonstrates how to use the **SendKey** method in conjunction with the **KeyMapped** and **KeyPress** events in the Terminal Emulator control:

```
Private Sub Terminal1_KeyMapped(KeyIndex As Integer, Shift As Integer, KeyString As String)
    TelnetClient1.SendKey KeyString
End Sub

Private Sub Terminal1_KeyPress(KeyAscii As Integer)
    TelnetClient1.SendKey KeyAscii
End Sub
```

See Also

[IsWritable Property](#), [Write Method](#), [OnWrite Event](#)

Uninitialize Method

Uninitialize the control and release any system resources that were allocated.

Syntax

object.Uninitialize

Parameters

None.

Return Value

None.

Remarks

The **Uninitialize** method terminates any connection established by the control and resets the internal state of the control. This method is not typically used because any resources that have been allocated by an instance of the control will automatically be released when it is destroyed.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the control will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the control was created. An application should only call the **Uninitialize** method if it has explicitly called the **Initialize** method.

See Also

[Initialize Method](#)

Write Method

Write data to the server.

Syntax

object.Write(*Buffer*, [*Length*])

Parameters

Buffer

A buffer variable that contains the data to be written to the server. If the variable is a **String** type, then the data will be written as a string of characters. This is the most appropriate data type to use if the server expects text data that consists of printable characters. If the server is expecting binary data, it is recommended that a **Byte** array be used instead.

Length

A numeric value which specifies the number of bytes to write. Its maximum value is $2^{31}-1 = 2147483647$. If a value is specified for this argument and it is greater than the actual size of the buffer, then the **Length** argument will be ignored and the entire contents of the buffer will be written. If the argument is omitted, then the maximum number of bytes to write is determined by the size of the buffer.

Return Value

This method returns the number of bytes actually written to the server, or -1 if an error was encountered.

Remarks

The **Write** method sends the data in *buffer* to the server. If the connection is buffered, as is typically the case, the data is copied to the send buffer and control immediately returns to the program. If the control is blocking, the application will wait until the data can be sent. If the control is non-blocking and the write fails because it could not send all of the data to the server, the **OnWrite** event will be fired when the server can accept data again.

If the data contains binary characters, particularly non-printable control characters and embedded nulls, you should always provide a **Byte** array to the **Write** method. When you provide a **String** variable as the buffer, the control will process the data as text. If the string contains Unicode characters, it will automatically be converted to 8-bit ANSI encoded text prior to being written. Using a byte array ensures that binary data will be sent as-is without being encoded.

[CodePage Property](#), [IsConnected Property](#), [IsWritable Property](#), [Timeout Property](#), [Read Method](#), [SendKey Method](#), [OnWrite Event](#)

WriteLine Method

Send a line of text to the server, terminated by a carriage-return and linefeed.

Syntax

object.WriteLine([*Buffer*])

Parameters

Buffer

A string which contains the data that will be sent to the server. The data will always be terminated with a carriage-return and linefeed control character sequence. If this argument is omitted, then a only a carriage-return and linefeed are written to the socket. Note that if the string contains a null character, any data that follows the null character will be discarded.

Return Value

This method returns true if the contents of the string has been written to the server. If an error occurs, the method will return False.

Remarks

The **WriteLine** method writes a line of text to the server and terminates the line with a carriage-return and linefeed control character sequence. Unlike the **Write** method which writes arbitrary bytes of data to the socket, this method is specifically designed to write a single line of text data from a string.

If the *Buffer* string is terminated with a linefeed (LF) or carriage return (CR) character, it will be automatically converted to a standard CRLF end-of-line sequence. Because the string will be sent with a terminating CRLF sequence, the number of characters sent to the remote host will typically be larger than the original string length (reflecting the additional CR and LF characters), unless the string was already terminated with CRLF.

The **WriteLine** method should only be used to send text, never binary data. In particular, the function will discard any data that follows a null character and will append linefeed and carriage return control characters to the data stream. Calling this this method will force the thread to block until the complete line of text has been written, the write operation times out or the server aborts the connection. If this function is called with the **Blocking** property set to False, it will automatically switch the socket into a blocking mode, send the data and then restore the socket to non-blocking mode. If another socket operation is attempted while the **WriteLine** method is blocked sending data to the server, an error will occur. It is recommended that this method only be used with blocking socket connections.

The **Write** and **WriteLine** methods can be safely intermixed.

Telnet Protocol Control Events

Event	Description
OnCancel	This event occurs when a blocking operation is canceled
OnConnect	This event occurs when a connection is established
OnDisconnect	This event occurs when a connection is terminated
OnError	This event occurs when a control error occurs
OnRead	This event occurs when data is available to be read
OnTimeout	This event occurs when a blocking operation times out
OnWrite	This event occurs when data can be written to the server

OnCancel Event

The **OnCancel** event is generated when a blocking operation is canceled.

Syntax

Sub *object_OnCancel* ([*Index As Integer*])

Remarks

This event occurs when a blocking operation on the socket, such as sending or receiving data, is canceled with the **Cancel** method. To assist in determining which operation was canceled, consult the **State** property.

See Also

[Cancel Method](#), [OnError Event](#), [OnTimeout Event](#)

OnConnect Event

The **OnConnect** event is generated when a connection is established.

Syntax

Sub *object_OnConnect* ([*Index As Integer*])

Remarks

The **OnConnect** event is generated when a connection is made with a server as a result of a **Connect** method call. This event is only triggered when the **Blocking** property is set to False.

See Also

[Blocking Property](#), [Connect Method](#), [OnDisconnect Event](#), [OnWrite Event](#)

OnDisconnect Event

The **OnDisconnect** event is generated when a connection is terminated.

Syntax

Sub *object_OnDisconnect* ([*Index As Integer*])

Remarks

The **OnDisconnect** event is generated when the connection is terminated by the server. This event is only triggered when the **Blocking** property is set to False.

When the **OnDisconnect** event fires, it is possible that there may still be buffered data available to read from the server. Before disconnecting from the server, the application should attempt to read any remaining data until the **Read** method returns a value of zero, or returns an error indicating that the operation would block.

See Also

[Blocking Property](#), [IsConnected Property](#), [IsReadable Property](#), [Connect Method](#), [Disconnect Method](#), [Read Method](#), [OnConnect Event](#)

OnError Event

The **OnError** event is generated when a control error occurs.

Syntax

```
Sub object_OnError ( [Index As Integer,] ByVal ErrorCode As Variant, ByVal Description As Variant )
```

Remarks

This event occurs when an error occurs during a control action. Errors not generated by the control itself, such as errors related to the programming language or general component errors, do not trigger this event.

The ***ErrorCode*** argument specifies the last error that has occurred. If the error is network related, the error code values returned by the control correspond to those returned by the standard Windows Sockets library.

The ***Description*** argument is a string that describes the error.

See Also

[LastError Property](#), [LastErrorString Property](#), [ThrowError Property](#)

OnRead Event

The **OnRead** event is generated when data is available to be read.

Syntax

Sub *object_OnRead* ([*Index As Integer*])

Remarks

The **OnRead** event is generated for non-blocking sockets when data is available to be read from the server. Use the **Read** method to read the data. This event is only triggered when the **Blocking** property is set to False.

See Also

[IsReadable Property](#), [Read Method](#), [Write Method](#), [OnWrite Event](#)

OnTimeout Event

The **OnTimeout** event is fired when a blocking operation times out.

Syntax

Sub *object_OnTimeout* ([*Index As Integer*])

Remarks

The **OnTimeout** event is generated when a blocking socket operation, such as sending or receiving data, times out. To determine which operation was in progress when the timeout occurred, consult the **State** property. This event is only triggered when the **Blocking** property is set to True.

See Also

[Timeout Property](#), [OnCancel Event](#)

OnWrite Event

The **OnWrite** event is generated when data can be written to the server.

Syntax

Sub *object_OnWrite* ([*Index As Integer*])

Remarks

The **OnWrite** event is generated for non-blocking sockets when data can be written to the server after a previous attempt failed because it would cause the control to block. This event is only triggered when the **Blocking** property is set to False.

Terminal Emulation Control

Emulate an ANSI or DEC VT-220 character mode display terminal.

Reference

- [Properties](#)
- [Methods](#)
- [Events](#)

Control Information

Object Name	TerminalCtl.Terminal
File Name	CSNVTX12.OCX
Version	12.0.3024.1286
ProgID	SocketTools.Terminal.12
ClassID	CD00CE8C-AC51-46DF-B978-3949557B7F57
Threading Model	Apartment
Help File	CST12CTL.CHM
Dependencies	None

Remarks

The Terminal Emulation control provides a comprehensive interface for emulating an ANSI or DEC-VT220 terminal, with full support for all standard escape and control sequences, color mapping and other advanced features. The control provides both a high level interface for parsing escape sequences and updating a display, as well as lower level primitives for directly managing the virtual display, such as controlling the individual display cells, moving the cursor position and specifying display attributes.

Requirements

The SocketTools ActiveX Edition components are self-registering controls that are compatible with any programming language that supports the Component Object Model (COM) and the ActiveX control specification. If you are using Visual Basic 6.0, Service Pack 6 (SP6) is required. We recommend installing all available updates for your development tools. Although the Visual Basic 6.0 runtime is supported on Windows 11, the IDE itself is no longer officially supported by Microsoft. Legacy IDEs and compilers may also require elevated (administrator) privileges to run properly.

The ActiveX controls are supported on Windows 7, Windows Server 2008 R2, and later versions of both desktop and server editions of Windows. For Windows 7, Service Pack 1 (SP1) is the minimum requirement. For Windows 8 systems, the 8.1 update must be installed. On ARM-based platforms, the minimum supported version is Windows 10 build 1709.

SocketTools includes components for both 32-bit (x86) and 64-bit (x64) Windows platforms. All modern versions of Windows are 64-bit, but we continue to include 32-bit components for compatibility with legacy development tools such as Visual Basic 6.0. We also provide native ARM64 ActiveX controls for systems running Windows on ARM. Note that 32-bit applications on ARM run using x86 emulation, and Microsoft no longer supports native ARM32 applications.

If you are using VBScript, Visual Basic for Applications (VBA), or another scripting environment on an ARM-based system, be aware that 64-bit hosts will require ARM64 components, while 32-bit hosts will use x86 components under emulation. This includes applications created with Visual Basic 6.0. To reduce deployment complexity and avoid confusion, SocketTools does not include ARM32 ActiveX controls in its standard redistribution packages but they are available on request for legacy or specialized scenarios.

Distribution

When you distribute an application that uses this control, you should install the appropriate file in the Windows system directory. ActiveX controls must be registered on the target system by the installation program before they can be used by an application.

Terminal Emulator Control Properties

Property	Description
Attributes	Gets and sets the current display attribute for the terminal emulator
AutoRefresh	Enable or disable the automatic refreshing of the virtual display
AutoSelect	Enable or disable the automatic selection of text in the display
AutoWrap	Enable or disable the wrapping of text in the emulation window
BackColor	Sets or returns the background color for the control.
Bell	Enable or disable the audible bell
BoldColor	Sets or returns the bold color for the control.
Cell	Returns information about the specified character cell in the display
CellHeight	Return the height of a text cell
CellWidth	Return the width of a text cell
CodePage	Gets and sets the code page used when reading and writing text
ColorMap	Gets and sets the RGB value used when displaying color text attributes
Columns	Gets and sets the number of columns in the emulation display
Cursor	Enable or disable the display of the cursor in the emulation window
CursorStyle	Gets and sets the style of cursor used in the emulator
CursorX	Gets and sets the current cursor position in the display
CursorY	Gets and sets the current cursor position in the display
Emulation	Gets and sets the emulation used by the control
Font	Returns the Font object used by the terminal emulator
FontBold	Gets and sets the bold style for the current font
FontName	Gets and sets the name of the current font
FontSize	Gets and sets the point size of the current font
ForeColor	Sets or returns the foreground color for the control.
hWnd	Returns a handle to the control window
KeyMap	Gets and sets the character sequence mapped to a special key
MouseX	Return the current mouse pointer position in the display
MouseY	Return the current mouse pointer position in the display
MousePointer	Gets and sets the type of pointer which is displayed when the mouse is positioned over the control window
NewLine	Determine how carriage returns and linefeeds are displayed
Rows	Gets and sets the number of rows in the emulation display
ScrollBars	Returns or sets a value indicating whether the control has horizontal or vertical scroll bars
SelLength	Gets and sets the number of characters selected
SelStart	Gets and sets the starting position of the current text selection
SelText	Returns the selected text or text from a specific portion of the display
Text	Gets and sets the text displayed by the control
Version	Return the current version of the control

Attributes Property

Gets and sets the current display attribute for the terminal emulator.

Syntax

object.Attributes [= *attributes*]

Remarks

The **Attributes** property can be used to determine the current display attributes, or to change the current attribute for subsequent text. The following table lists the attributes that are recognized by the control.

Value	Description
nvtAttributeNormal	Normal, default attributes.
nvtAttributeReverse	Foreground and background cell colors are reversed.
nvtAttributeBold	The character is displayed using a higher intensity color.
nvtAttributeDim	The character is displayed using a lower intensity color.
nvtAttributeUnderline	The character is displayed with an underline.
nvtAttributeHidden	The character is stored in display memory, but not shown.
nvtAttributeProtect	The character is protected and cannot be cleared.

Data Type

Integer (Int32)

See Also

[BoldColor Property](#), [Cell Property](#), [CursorStyle Property](#)

AutoRefresh Property

Enable or disable the automatic refreshing of the virtual display.

Syntax

object.AutoRefresh [= { True | False }]]

Remarks

The **AutoRefresh** property is used to enable or disable the automatic refreshing of the virtual display whenever characters are written or the cursor position changes. By setting the property to False, the display can be changed and those changes will not be displayed until the property is reset to True. This allows an application to make a series of changes to the display text, attributes or cursor position without causing it to flicker.

Data Type

Boolean

See Also

[Attributes Property](#), [Refresh Method](#), [Write Method](#)

AutoSelect Property

Enable or disable the automatic selection of text in the display.

Syntax

object.**AutoSelect** [= { True | False }]]

Remarks

The **AutoSelect** property is used to enable or disable the automatic selection of text in the virtual display. When the property is set to True, the user can select text by clicking and dragging the mouse over the text to be selected. When set to False, no text is selected if the user drags the mouse over the display.

Data Type

Boolean

See Also

[SelText Property](#), [Select Method](#)

AutoWrap Property

Enable or disable the wrapping of text in the emulation window.

Syntax

object.AutoWrap [= { True | False }]]

Remarks

The AutoWrap property enables or disables the wrapping of text in the emulation window. If set to True, when text reaches last column in the display, the cursor is re-positioned to the first column on the next line. If set to False, any text displayed beyond the last column is discarded.

Data Type

Integer (Int32)

See Also

[Bell Property](#), [Columns Property](#), [Emulation Property](#), [Rows Property](#)

BackColor Property

Sets or returns the background color for the control.

Syntax

object.BackColor [= *color*]

Remarks

The **BackColor** property returns the current background color for the control. Setting the property changes the color to the specified value.

Colors are RGB (Red Green Blue) values which range from 0 to 16,777,215 (&HFFFFFF). The high byte of a number in this range equals 0; the lower 3 bytes, from least to most significant byte, determine the amount of red, green, and blue, respectively. The red, green, and blue components are each represented by a number between 0 and 255 (&HFF). If the high byte isn't 0, the control uses the system colors, as defined in the user's Control Panel settings.

The following table lists the standard system color values and the Control panel settings that they correspond to:

Color Value	Definition	Control Panel Setting
80000000h	Scrollbar background	
80000001h	Desktop	Desktop
80000002h	Active window caption	Active Title Bar
80000003h	Inactive window caption	Inactive Title Bar
80000004h	Menu background	Menu
80000005h	Window background	Window
80000006h	Window frame	
80000007h	Menu text	Menu
80000008h	Window text	Window
80000009h	Window caption text	Active Title Bar
8000000Ah	Active window border	Active Window Border
8000000Bh	Inactive window border	Inactive Window Border
8000000Ch	Background color	Application Background
8000000Dh	Items selected in a control	Selected Items
8000000Eh	Text of items selected in a control	Selected Items
8000000Fh	Face shading on push buttons	
80000010h	Edge shading on push buttons	
80000011h	Disabled text	
80000012h	Text on push buttons	Caption Buttons
80000013h	Text color for an inactive caption	Inactive Title Bar

80000014h	Highlight color for buttons	
80000015h	Dark color for 3D display elements	
80000016h	Light color for 3D display elements	
80000017h	Text color for ToolTip controls	ToolTip
80000018h	Background color for ToolTip controls	ToolTip

Data Type

Integer (Int32)

See Also

[BoldColor Property](#), [ColorMap Property](#), [ForeColor Property](#)

Bell Property

Enable or disable the audible bell.

Syntax

object.**Bell** [= { True | False }]]

Remarks

The **Bell** property enables or disables the audible bell which is played whenever the control character Ctrl+G is encountered. The default property value is True.

Data Type

Boolean

See Also

[AutoWrap Property](#), [Cursor Property](#)

BoldColor Property

Sets or returns the bold color for the control.

Syntax

`object.BoldColor [= color ]`

Remarks

The **BoldColor** property returns the current color used for bold text in the control. Setting the property changes the color to the specified value.

Colors are RGB (Red Green Blue) values which range from 0 to 16,777,215 (&HFFFFFF). The high byte of a number in this range equals 0; the lower 3 bytes, from least to most significant byte, determine the amount of red, green, and blue, respectively. The red, green, and blue components are each represented by a number between 0 and 255 (&HFF). If the high byte isn't 0, the control uses the system colors, as defined in the user's Control Panel settings.

The following table lists the standard system color values and the Control panel settings that they correspond to:

Color Value	Definition	Control Panel Setting
80000000h	Scrollbar background	
80000001h	Desktop	Desktop
80000002h	Active window caption	Active Title Bar
80000003h	Inactive window caption	Inactive Title Bar
80000004h	Menu background	Menu
80000005h	Window background	Window
80000006h	Window frame	
80000007h	Menu text	Menu
80000008h	Window text	Window
80000009h	Window caption text	Active Title Bar
8000000Ah	Active window border	Active Window Border
8000000Bh	Inactive window border	Inactive Window Border
8000000Ch	Background color	Application Background
8000000Dh	Items selected in a control	Selected Items
8000000Eh	Text of items selected in a control	Selected Items
8000000Fh	Face shading on push buttons	
80000010h	Edge shading on push buttons	
80000011h	Disabled text	
80000012h	Text on push buttons	Caption Buttons
80000013h	Text color for an inactive caption	Inactive Title Bar

80000014h	Highlight color for buttons	
80000015h	Dark color for 3D display elements	
80000016h	Light color for 3D display elements	
80000017h	Text color for ToolTip controls	ToolTip
80000018h	Background color for ToolTip controls	ToolTip

Data Type

Integer (Int32)

See Also

[BackColor Property](#), [ColorMap Property](#), [ForeColor Property](#)

Cell Property

Returns information about the specified character cell in the display.

Syntax

object.Cell(*X*, *Y*)

Remarks

The **Cell** property returns information about the specified character cell in the display at the specified X and Y cursor position.

The value returned by the **Cell** property is a 32-bit integer value, where the low order word specifies the ANSI character stored at that position and the high order word specifies the display attributes for that cell.

The character cell attributes may be one or more of the following values:

Value	Description
nvtAttributeNormal	Normal, default attributes.
nvtAttributeReverse	Foreground and background cell colors are reversed.
nvtAttributeBold	The character is displayed using a higher intensity color.
nvtAttributeDim	The character is displayed using a lower intensity color.
nvtAttributeUnderline	The character is displayed with an underline.
nvtAttributeHidden	The character is stored in display memory, but not shown.
nvtAttributeProtect	The character is protected and cannot be cleared.

One or more attributes may be combined using a bitwise Or operator. Certain attributes, such as **nvtAttributeBold** and **nvtAttributeDim** are mutually exclusive.

Data Type

Integer (Int32)

Example

To access the high and low words of the value returned by the **Cell** property in Visual Basic 6, it's useful to implement two helper functions:

```
Public Function LoWord(DWord As Long) As Integer
    If DWord And &H8000& Then
        LoWord = DWord Or &HFFFF0000
    Else
        LoWord = DWord And &HFFFF&
    End If
End Function
```

```
Public Function HiWord(DWord As Long) As Integer
    HiWord = (DWord And &HFFFF0000) \ &H10000
End Function
```

You can then use those functions to get the character and attributes for the cell:

```
Dim nCell As Long
Dim nChar As Integer
```

Dim nAttribute As Integer

nCell = Terminal1.Cell(xPos, yPos)

nChar = LoWord(nCell)

nAttribute = HiWord(nCell)

See Also

[Attributes Property](#)

CellHeight Property

Return the height of a text cell.

Syntax

object.CellHeight

Remarks

The **CellHeight** property returns the height of a text cell in pixels. This value can be used in calculating the minimum height of the display window in order to display all lines of text.

Data Type

Integer (Int32)

See Also

[CellWidth Property](#)

CellWidth Property

Return the width of a text cell.

Syntax

object.CellWidth

Remarks

The **CellWidth** property returns the width of a text cell in pixels. This value can be used in calculating the minimum width of the display window in order to display all text columns.

Data Type

Integer (Int32)

See Also

[CellHeight Property](#)

CodePage Property

Gets and sets the code page used when reading and writing text.

Syntax

object.CodePage [= *value*]

Remarks

The **CodePage** property is an integer value which specifies how strings are encoded when data is sent or received. Any valid code page identifier may be specified. Some common values are:

Value	Description
0	Text sent and received using a string should be converted using the ANSI code page for the current locale.
1	Text sent and received using a string should be converted using the system default OEM code page. The OEM code page typically contains characters that are used by console applications and are based on character sets commonly used by MS-DOS. You should not use this code page unless you know the server is sending text which includes OEM characters.
1252	Text sent and received using a string should be converted using the Windows ANSI code page for western European languages. This code page is commonly used by legacy Windows applications for English and some other western languages. It should be noted that while this code page is similar to ISO 8859-1 character encoding, it is not identical.
28591	Text sent and received using a string should be converted using the ISO 8859-1 code page for western European languages. This code page is commonly referred to as Latin-1 and is similar to the Windows 1252 code page.
65000	Data that is sent and received using a string should be converted using UTF-7 encoding. If this code page is specified, data written to the socket will be encoded as UTF-7 encoded Unicode. All data received from the server will be converted from UTF-7. It is not recommended that you use this code page unless you know that the remote host is sending UTF-7 encoded text.
65001	Data that is sent and received using a string should be converted using UTF-8 encoding. If this code page is specified, data written to the socket will be encoded as UTF-8 encoded Unicode. All data received from the server will be converted from UTF-8 to UTF-16 Unicode. Because UTF-8 is backwards compatible with the ASCII character set, it is safe to use this encoding option when sending and receiving ASCII text.

A complete list of available [code page identifiers](#) can be found in Microsoft's documentation for the Win32 API.

By default, strings are converted to an array of bytes using the code page for the current locale, mapping the 16-bit Unicode characters to bytes which are written to the virtual display. Similarly, when copying characters from the display into a string buffer, those characters are converted to Unicode before they are returned to your application.

For backwards compatibility, the control defaults to using the code page for the current locale. This property value directly corresponds to Windows code page identifiers, and will accept any valid code

page in addition to the values listed above. Setting this property to an invalid code page will result in an error.

Data Type

Integer (Int32)

See Also

[SelText Property](#), [Text Property](#), [Write Method](#)

ColorMap Property

Gets and sets the RGB value used when displaying color text attributes.

Syntax

`object.ColorMap(Index) [= color ]`

Remarks

The **ColorMap** property array provides access to the virtual display color table which determines what RGB values are used to display foreground and background text color attributes.

When the emulator processes an escape sequence that changes the current foreground or background color, the actual RGB color value is determined by looking up the value in the virtual display's color table. The **ColorMap** property is useful for determining what values are being used when a color attribute is set and enables an application to change those colors. The emulator currently supports a maximum of sixteen (16) color values, and the index into the table corresponds to the color as defined by the standard for ANSI terminals:

Index	Color	Default (Hex)	Default (Integer)	Default (RGB)
Black	RGB(0,0,0)			
Red	000000A0h	RGB(160,0,0)		
Green	0000A000h	RGB(0,160,0)		
Yellow	0000A0A0h	RGB(160,160,0)		
Blue	00A00000h	RGB(0,0,160)		
Magenta	00A000A0h	RGB(160,0,160)		
Cyan	00A0A000h	RGB(0,160,160)		
White	00E0E0E0h	RGB(224,224,224)		
Gray	00C0C0C0h	RGB(192,192,192)		
Light Red	008080FFh	RGB(255,128,128)		
Light Green	0090EE90h	RGB(144,238,144)		
Light Yellow	00C0FFFFh	RGB(255,255,192)		
Light Blue	00E6D8ADh	RGB(173,216,230)		
Light Magenta	00FFC0FFh	RGB(255,192,255)		
Light Cyan	00FFFFE0h	RGB(224,255,255)		
High White	00FFFFFFh	RGB(255,255,255)		

A standard ANSI color terminal supports eight standard colors (0-7). To select a foreground color, you add 30 to the color index and pass that value as a parameter to the SGR (select graphic rendition) escape sequence. To select a background color, you add 40 to the color index. For example, to set the current foreground color to white and the background color to blue, you could send the following escape sequence:

ESC [37;44 m

Note that if you wanted to set the foreground color to a bold version of standard yellow, you

would first set the bold attribute, and then use the index value of 3, such as:

ESC [1;33m

Changing the value of the **ColorMap** property array allows the application to make selective changes to the actual RGB color value that is used when a color attribute is set. Note that changes to the color map will only affect new characters as they are displayed, not any previously displayed characters.

Data Type

Integer (Int32)

See Also

[BackColor Property](#), [BoldColor Property](#), [Cell Property](#), [ForeColor Property](#)

Columns Property

Gets and sets the number of columns in the emulation display.

Syntax

object.Columns [= *columns*]

Remarks

The **Columns** property returns the number of columns in the emulation window, or allows the application to change the number of columns. Currently, the number of columns may only be set to 80 or 132. Note that changing the number of columns in the display causes the current display to be invalidated, and the window will be cleared.

Data Type

Integer (Int32)

See Also

[CellHeight Property](#), [CellWidth Property](#), [Rows Property](#), [ScrollBars Property](#)

Cursor Property

Enable or disable the display of the cursor in the emulation window.

Syntax

object.**Cursor** [= { True | False }]]

Remarks

The **Cursor** property enables or disables the display of the cursor in the emulation window. The default property value is True.

Data Type

Boolean

See Also

[CursorStyle Property](#), [Emulation Property](#)

CursorStyle Property

Gets and sets the style of cursor used in the emulator.

Syntax

object.CursorStyle [= *style*]

Remarks

The **CursorStyle** property determines how the cursor is displayed in the emulation window. The following values may be used.

Value	Description
nvtUnderline	The cursor is displayed as an underline
nvtBlock	The cursor is displayed as a block that is the full height of the character cell

Data Type

Integer (Int32)

See Also

[Cursor Property](#)

CursorX Property

Gets and sets the current cursor position in the display.

Syntax

object.CursorX [= *column*]

Remarks

The **CursorX** property returns the current position of the cursor in the display, or can be used to change the current position. The current position is given in columns and indicates where the next text character will be displayed. To calculate the pixel offset where the cursor is located in the control window, multiply this value by the **CellWidth** property value.

Data Type

Integer (Int32)

See Also

[CellWidth Property](#), [Cursor Property](#), [CursorStyle Property](#), [CursorY Property](#), [MouseX Property](#), [MouseY Property](#)

CursorY Property

Gets and sets the current cursor position in the display.

Syntax

object.CursorY [= *row*]

Remarks

The **CursorY** property returns the current position of the cursor in the display, or can be used to change the current position. The current position is given in rows and indicates where the next text character will be displayed. To calculate the pixel offset where the cursor is located in the control window, multiply this value by the **CellHeight** property value.

Data Type

Integer (Int32)

See Also

[CellHeight Property](#), [Cursor Property](#), [CursorStyle Property](#), [CursorX Property](#)

Emulation Property

Gets and sets the emulation used by the control.

Syntax

object.Emulation [= *type*]

Remarks

The **Emulation** property can be used to set or return the type of emulation performed by the control. The following values may be used:

Value	Description
nvtNone	The virtual display does not emulate any specific terminal type, and does not process any escape sequences.
nvtANSI	The virtual display processes ANSI escape sequences for screen management and cursor positioning. This emulation also supports escape sequences to control the foreground and background color. The default keymap for ANSI function key escape sequences will be selected. This is the default value.
nvtVT100	The virtual display processes DEC VT-100 escape sequences for screen management and cursor positioning. The default keymap for a DEC VT-100 terminal will be selected.
nvtVT220	The virtual display processes DEC VT-220 escape sequences for screen management and cursor positioning. This emulation also supports DEC VT-320 escape sequences to control the foreground and background color. The default keymap for a DEC VT-220 terminal will be selected.

Data Type

Integer (Int32)

See Also

[AutoWrap Property](#), [Cursor Property](#), [Write Method](#)

Font Property

Returns the Font object used by the terminal emulator.

Syntax

object.Font

Remarks

The **Font** property returns the Font object which is used by the control. The Font object determines the font name and attributes which are used when drawing text in the virtual display. The control expects that the font will be fixed-width, where the width and height of each character is the same. The use of a variable width font may cause the control to display the cursor in the wrong location.

By default, the control will use the standard Terminal font, which is a fixed-width OEM font that is suitable for most applications.

Data Type

Font Object

Example

The following example demonstrates how to use the **Font** property to change the name of the font used by the control:

```
Terminal1.Font.Name = "Lucida Console"
```

See Also

[FontBold Property](#), [FontName Property](#), [FontSize Property](#)

FontBold Property

Gets and sets the bold style for the current font.

Syntax

object.FontBold [= { True | False }]

Remarks

The **FontBold** property returns True if the current font style has the bold attribute enabled. Setting this property changes the style for the current font. Changing the **Bold** property of the object returned by the **Font** property will automatically update this property.

This property is provided for compatibility with languages which do not support the standard Font object, or where using the Font object interface is difficult. When possible, it is recommended that programs use the **Font** property instead.

Data Type

Boolean

See Also

[Font Property](#), [FontName Property](#), [FontSize Property](#)

FontName Property

Gets and sets the name of the current font.

Syntax

object.FontName [= *fontname*]

Remarks

The **FontName** property returns the name of the current font. Setting this property changes the font which is used by the control to display text. Changing the **Name** property of the object returned by the **Font** property will automatically update this property.

The control expects that the font will be fixed-width, where the width and height of each character is the same. The use of a variable width font may cause the control to display the cursor in the wrong location.

This property is provided for compatibility with languages which do not support the standard Font object, or where using the Font object interface is difficult. When possible, it is recommended that programs use the **Font** property instead.

Data Type

String

See Also

[Font Property](#), [FontBold Property](#), [FontSize Property](#)

FontSize Property

Gets and sets the point size of the current font.

Syntax

object.FontSize [= *fontsize*]

Remarks

The **FontSize** property returns the size of the current font. Setting this property changes the size of the font which the control uses to display text. Changing the **Size** property of the object returned by the **Font** property will automatically update this property.

This property is provided for compatibility with languages which do not support the standard Font object, or where using the Font object interface is difficult. When possible, it is recommended that programs use the **Font** property instead.

Data Type

Integer (Int32)

See Also

[Font Property](#), [FontBold Property](#), [FontName Property](#)

ForeColor Property

Sets or returns the foreground color for the control.

Syntax

object.ForeColor [= *color*]

Remarks

The **ForeColor** property returns the current foreground color for the control. Setting the property changes the color to the specified value.

Colors are RGB (Red Green Blue) values which range from 0 to 16,777,215 (&HFFFFFF). The high byte of a number in this range equals 0; the lower 3 bytes, from least to most significant byte, determine the amount of red, green, and blue, respectively. The red, green, and blue components are each represented by a number between 0 and 255 (&HFF). If the high byte isn't 0, the control uses the system colors, as defined in the user's Control Panel settings.

The following table lists the standard system color values and the Control panel settings that they correspond to:

Color Value	Definition	Control Panel Setting
80000000h	Scrollbar background	
80000001h	Desktop	Desktop
80000002h	Active window caption	Active Title Bar
80000003h	Inactive window caption	Inactive Title Bar
80000004h	Menu background	Menu
80000005h	Window background	Window
80000006h	Window frame	
80000007h	Menu text	Menu
80000008h	Window text	Window
80000009h	Window caption text	Active Title Bar
8000000Ah	Active window border	Active Window Border
8000000Bh	Inactive window border	Inactive Window Border
8000000Ch	Background color	Application Background
8000000Dh	Items selected in a control	Selected Items
8000000Eh	Text of items selected in a control	Selected Items
8000000Fh	Face shading on push buttons	
80000010h	Edge shading on push buttons	
80000011h	Disabled text	
80000012h	Text on push buttons	Caption Buttons
80000013h	Text color for an inactive caption	Inactive Title Bar

80000014h	Highlight color for buttons	
80000015h	Dark color for 3D display elements	
80000016h	Light color for 3D display elements	
80000017h	Text color for ToolTip controls	ToolTip
80000018h	Background color for ToolTip controls	ToolTip

Data Type

Integer (Int32)

See Also

[BackColor Property](#), [BoldColor Property](#), [ColorMap Property](#)

hWnd Property

Returns a handle to the control window.

Syntax

object.**hWnd**

Remarks

The **hWnd** property returns the handle to the control window. The Windows operating system identifies each form or control in an application by assigning it a numeric value called a handle, or hWnd. This handle is required by many Windows API functions which can be used to control the behavior and appearance of a window. For more information, refer to the Windows User Interface documentation or the Windows API technical reference which is part of the Microsoft Windows SDK.

Note that because the **hWnd** property value can change while the program is running, you should never store the value in a variable.

Data Type

Integer (Int32)

KeyMap Property

Gets and sets the character sequence mapped to a special key.

Syntax

object.KeyMap(*Index*) [= *value*]

Remarks

The **KeyMap** property array allows the application to define character sequences that should be mapped to special keys. When a special key is pressed in the emulation window and there is an entry for it in the key map, the **KeyMapped** event is fired.

The property array index identifies the key which will be mapped. Refer to the [KeyMap Constants](#) table for a list of keys and their corresponding values which may be mapped by the application.

Data Type

String

See Also

[KeyMapped Event](#)

MousePointer Property

Gets and sets the type of pointer which is displayed when the mouse is positioned over the control window.

Syntax

object.**MousePointer** [= *pointer*]

Remarks

The **MousePointer** property returns the type of pointer that is currently displayed when the mouse is positioned over the control window. Setting the property changes the type of mouse pointer that is displayed. This can be useful if you wish to indicate a change in functionality, such as changing the pointer to an hourglass when the program is busy processing information.

The following values may be assigned to this property:

Value	Description
nvtDefault	The default mouse pointer
nvtArrow	Arrow pointer
nvtCrosshair	Crosshair pointer
nvtIBeam	I-beam pointer, commonly used when editing text
nvtIcon	Icon pointer, a small square within a square
nvtSize	Size pointer, four point arrow pointing north, south, east and west
nvtSizeNESW	Size pointer, arrows pointing northeast and southwest
nvtSizeSN	Size pointer, arrows pointing north and south
nvtSizeNWSE	Size pointer, arrows pointing northwest and southeast
nvtSizeWE	Size pointer, arrows pointing west and east
nvtUpArrow	Up arrow pointer
nvtHourglass	Hourglass pointer
nvtNoDrop	No drop pointer, a circle with a slash through it
nvtArrowHourglass	Arrow pointer with a small hourglass
nvtArrowQuestion	Arrow pointer with a small question mark
nvtArrowSizeAll	Size all pointer

Data Type

Integer (Int32)

Example

The following example sets the MousePointer to an hourglass, which is typically used to indicate to the user that they program is busy and that they should wait for it to complete the current operation:

```
Terminal1.MousePointer = nvtHourglass
```

See Also

MouseX Property

Return the current mouse pointer position in the display.

Syntax

object.**MouseX**

Remarks

The **MouseX** property returns the current position of the mouse pointer in the display. The current position is given in columns, not pixels. To calculate the pixel offset where the mouse pointer is located in the control window, multiply this value by the **CellWidth** property value.

Data Type

Integer (Int32)

See Also

[CellWidth Property](#), [CursorX Property](#), [CursorY Property](#), [MouseY Property](#)

MouseY Property

Return the current mouse pointer position in the display.

Syntax

object.**MouseY**

Remarks

The **MouseY** property returns return the current position of the mouse pointer in the display. The current position is given in rows, not pixels. To calculate the pixel offset where the mouse pointer is located in the control window, multiply this value by the **CellHeight** property value.

Data Type

Integer (Int32)

See Also

[CellHeight Property](#), [CursorX Property](#), [CursorY Property](#), [MouseX Property](#)

NewLine Property

Determine how carriage returns and linefeeds are displayed.

Syntax

object.NewLine [= *newline*]

Remarks

The **NewLine** property controls how carriage returns and linefeeds are processed by the emulator. The following values may be used:

Value	Description
nvtCRLF	A carriage return positions the cursor to the first column, and a linefeed advances the cursor to the next row, scrolling the display if necessary. This is the default value.
nvtCR	A carriage return positions the cursor to the first column and advances to the next row, scrolling the display if necessary.
nvtLF	A linefeed positions the cursor to the first column and advances to the next row, scrolling the display if necessary.

Data Type

Integer (Int32)

See Also

[AutoWrap Property](#), [Columns Property](#), [Write Method](#)

Rows Property

Gets and sets the number of rows in the emulation display.

Syntax

object.**Rows** [= *rows*]

Remarks

The **Rows** property returns the number of rows in the emulation window, or allows the application to change the number of rows. Changing the number of rows in the display causes the current display to be invalidated, and the window will be cleared.

Data Type

Integer (Int32)

See Also

[CellHeight Property](#), [CellWidth Property](#), [Columns Property](#), [ScrollBars Property](#)

ScrollBars Property

Description

Returns or sets a value indicating whether the control has horizontal or vertical scroll bars.

Syntax

object.ScrollBars [= *bartype*]

Remarks

The **ScrollBars** property determines what kind of scroll bars are displayed if the virtual display is larger than the emulation control's window. It may be one of the following values:

Value	Description
nvtSBNone	Do not display scrollbars
nvtHorizontal	Display a horizontal scrollbar if necessary
nvtVertical	Display a vertical scrollbar if necessary
nvtBoth	Display both horizontal and vertical scrollbars if necessary

Scroll bars are only displayed if needed. If the emulation window is large enough to display all of the columns and rows, no scrollbars will be drawn even if they are enabled using this property.

Data Type

Integer (Int32)

See Also

[CellHeight Property](#), [CellWidth Property](#), [Columns Property](#), [Rows Property](#)

SelLength Property

Gets and sets the number of characters selected.

Syntax

object.SelLength [= *length*]

Remarks

The **SelLength** property is used to return the number of characters currently selected in the emulation window. When used in conjunction with the **SelStart** property, it can be used to select text from the display.

Data Type

Integer (Int32)

See Also

[AutoSelect Property](#), [SelStart Property](#), [SelText Property](#), [Text Property](#), [Deselect Method](#), [Select Method](#)

SelStart Property

Gets and sets the starting position of the current text selection.

Syntax

object.SelStart [= *offset*]

Remarks

The **SelStart** property specifies an offset which is the starting position of the selected text. This property can be used in conjunction with the **SelLength** property to select text in the virtual display.

To convert the cursor position to an offset, multiply the y-position by the number of columns and add the x-position. The **SelLength** property determines the number of characters to copy from the starting position. Reading the **SelText** property returns the text displayed at the selected location.

Data Type

Integer (Int32)

See Also

[SelLength Property](#), [SelText Property](#), [Text Property](#), [Deselect Method](#), [Select Method](#)

SelText Property

Returns the selected text or text from a specific portion of the display.

Syntax

object.SelText

Remarks

The **SelText** property returns the text which is currently selected in the virtual display. If no text has been selected and the **SelLength** property is greater than zero, then the text starting at the position specified by the **SelStart** property will be returned.

To read a single character at a specific location in the display, it is preferable to use the **Cell** property rather than calculating the offset, setting the **SelStart** property and then reading the **SelText** property.

Data Type

String

See Also

[AutoSelect Property](#), [Cell Property](#), [CodePage Property](#), [SelLength Property](#), [SelStart Property](#), [Text Property](#), [Deselect Method](#), [Select Method](#)

Text Property

Gets and sets the text displayed by the control.

Syntax

object.**Text** [= *value*]

Remarks

The **Text** property returns the text displayed by the control. The string that is returned contains each row of text in the display, terminated with a carriage-return linefeed. Empty cells at the end of a row are ignored so there are no extraneous spaces in the text. In other words, the value returned by the **Text** property is similar to how text is returned from a multi-line edit control. If you need to access a character at a specific location in the display, use the **Cell** property. If you need to access the text in a specific part of the display, including any empty cells, then use the **SelStart**, **SelLength** and **SelText** properties instead.

Setting the **Text** property will cause the current contents of the display to be replaced by the contents of the specified string. If the string contains escape sequences and/or control characters, they will be processed according to how the **Emulation** property is set.

Data Type

String

See Also

[Cell Property](#), [CodePage Property](#), [Emulation Property](#), [SelLength Property](#), [SelStart Property](#), [SelText Property](#), [Write Method](#)

Version Property

Return the current version of the control.

Syntax

object.Version

Remarks

The **Version** property returns the current version of the object. This can be used by an application for validation purposes. The version returned is composed of four numbers, separated by periods. The first number is the major version number, the second number is the minor version number, the third is the build number and the fourth is the revision number.

Data Type

String

Terminal Emulator Control Methods

Method	Description
Clear	Clear the terminal emulation window
ClearEol	Erase all characters from the current column to the end of the line
DelLine	Delete the current line in the terminal emulation display
Deselect	Deselects any selected text in the display
Initialize	Initialize the control and validate the runtime license key
InsLine	Insert an empty line at the current position in the terminal emulation display
Refresh	Forces a complete redraw of the virtual display
Reset	Reset the internal state of the control
ScrollDown	Scroll the display down by one line
ScrollUp	Scroll the display up by one line
Select	Selects a region of the virtual display and returns the selected text
Uninitialize	Uninitialize the control
Write	Write data to virtual display

CellAttributes Method

Return the display attributes for the terminal emulator for a specified cell.

Syntax

object.Attribute(*X*, *Y*)

Parameters

X

An integer value that specifies a horizontal position in the virtual display buffer. This value must be in the range of 0 through the number of **Columns** -1.

Y

An integer value that specifies a vertical position in the virtual display buffer. This value must be in the range of 0 through the number of **Rows** -1.

Return Value

If an invalid position is specified, the method returns -1. Otherwise, the method returns a mask of graphic attributes for the display position. The following table lists the attributes that are recognized by the control. The value returned by the method is a combination of the bits that correspond to these values.

Value	Description
Normal display, no attributes enabled	
Reverse video attribute	
Bold attribute (use BoldColor color to display text)	
Dim attribute	
Blink attribute (not supported)	
Underline attribute	
Hidden attribute	
Protected attribute (not supported)	
Graphics attribute	

See Also

[Attributes Property](#), [Columns Property](#), [Rows Property](#)

Clear Method

Clear the terminal emulation window.

Syntax

object.Clear

Parameters

None.

Return Value

None.

See Also

[ClearEol Method](#), [DelLine Method](#), [InsLine Method](#), [Write Method](#)

ClearEol Method

Erase all characters from the current column to the end of the line.

Syntax

object.ClearEol

Parameters

None.

Return Value

None.

See Also

[Clear Method](#), [DelLine Method](#), [InsLine Method](#), [Write Method](#)

DelLine Method

Delete the current line in the terminal emulation display.

Syntax

object.DelLine

Parameters

None.

Return Value

None.

See Also

[Clear Method](#), [ClearEol Method](#), [InsLine Method](#), [Write Method](#)

Deselect Method

Deselects any selected text in the display.

Syntax

object.Deselect

Parameters

None.

Return Value

None.

Remarks

The **Deselect** method deselects any text that has been previously selected.

See Also

[AutoSelect Property](#), [SelText Property](#), [Select Method](#)

Initialize Method

Initialize the control and validate the runtime license key.

Syntax

object.Initialize([*LicenseKey*])

Parameters

LicenseKey

An optional string value which specifies a runtime license key used to initialize the control. If the license key is omitted or passed as an empty string, a development license must be installed on the local system.

Return Value

A value of zero is returned if the control was initialized successfully. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

This method dynamically loads other system libraries and allocates thread local storage. In most cases, it is not necessary to call this method directly because it is automatically invoked when an instance of the control is created by the container. However, if the control is created dynamically using **CreateObject** or a similar method, this must be the first method that is called before you attempt to modify any property values or invoke other methods. Failure to initialize the control may result in subsequent errors and/or cause an exception to be raised.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the control will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the control was created.

If the control is being used within another DLL, it is important that you do not attempt to create an instance of the control or call the **Initialize** method from within the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is written in C++ and it is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for any static and global C++ objects and has the same restrictions.

See Also

[Uninitialize Method](#)

InsLine Method

Insert an empty line at the current position in the terminal emulation display.

Syntax

object.InsLine

Parameters

None.

Return Value

No value is returned by this method.

See Also

[Clear Method](#), [ClearEol Method](#), [DelLine Method](#), [Write Method](#)

Refresh Method

Forces a complete redraw of the virtual display.

Syntax

object.Refresh

Parameters

None.

Return Value

None.

Remarks

The **Refresh** method forces the control to redraw the virtual display. Normally, the virtual display is automatically redrawn after the display has been modified and there are no other events being processed. However, there may be situations where you want the display updated immediately.

To prevent the control from automatically redrawing when the virtual display has been modified, set the **AutoRefresh** property to False. You can then call the **Refresh** method to force the control to be redrawn as needed.

See Also

[AutoRefresh Property](#)

Reset Method

Reset the internal state of the control.

Syntax

object.Reset

Parameters

None.

Return Value

None.

Remarks

The **Reset** method resets the internal state of the control. Property values are initialized to their internal defaults and the virtual display is recreated.

See Also

[Initialize Method](#), [Uninitialize Method](#)

ScrollDown Method

Scroll the display down by one line.

Syntax

object.ScrollDown

Parameters

None.

Return Value

None.

See Also

[DelLine Method](#), [InsLine Method](#), [ScrollUp Method](#)

ScrollUp Method

Scroll the display up by one line.

Syntax

object.ScrollUp

Parameters

None.

Return Value

None.

See Also

[DelLine Method](#), [InsLine Method](#), [ScrollDown Method](#)

Select Method

Selects a region of the virtual display and returns the selected text.

Syntax

```
object.Select( [Column1], [Row1], [Column2], [Row2], [Options] )
```

Parameters

- Column1**
A optional integer which specifies the starting column for the text selection. If this argument is omitted, the first column in the display is used.
- Row1**
A optional integer which specifies the starting row for the text selection. If this argument is omitted, the first row in the display is used.
- Column2**
A optional integer which specifies the ending column for the text selection. If this argument is omitted, the last column in the display is used.
- Row2**
A optional integer which specifies the ending row for the text selection. If this argument is omitted, the last row in the display is used.
- Options**
An optional integer value which specifies one or more options. More than one option can be combined using a bitwise operator. The following values may be used:

Value	Description
nvtSelectDefault	The default selection option. If there is a region of the display already selected, it will be cleared and the new region is selected. The selected text is buffered and can be accessed using the SelText property.
nvtSelectClipboard	Copy the selected text to the clipboard. If this option is not specified, the selected text is buffered and may be accessed using the SelText property.
nvtSelectNoRefresh	The display is not refreshed when the region is selected. This is useful if the application is going to be selecting multiple regions of the display, or combining more than one region, in order to minimize output to the window.
nvtSelectNoBuffer	Do not buffer the text in the selected region of the display. The display will show any text as being selected, but it will not be available to the application. This can be useful if the application is going to select multiple regions and combine them.
nvtSelectCombine	If there is already a region of the display that has been selected, the new region is combined with the previous region, selecting all of the text.

Return Value

The method will return the selected text. If the method fails because incorrect row or column values were used, or because an invalid option was specified, it will return an empty string.

Remarks

The **Select** method selects a region of the virtual display. This enables the application to select text in the same way that a user would by clicking and dragging the mouse over the display window. The **SelText** property can be used to return the text that has been selected by this method.

See Also

[AutoSelect Property](#), [SelText Property](#), [Deselect Method](#)

Uninitialize Method

Uninitialize the control and release any system resources that were allocated.

Syntax

object.Uninitialize

Parameters

None.

Return Value

None.

Remarks

The **Uninitialize** method destroys the virtual display and resets the internal state of the control. This method is not typically used because any resources that have been allocated by an instance of the control will automatically be released when it is destroyed.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the control will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the control was created. An application should only call the **Uninitialize** method if it has explicitly called the **Initialize** method.

[Initialize Method](#)

Write Method

Write data to virtual display.

Syntax

object.Write(*Buffer*, [*Length*])

Parameters

Buffer

A buffer variable that contains the data to be written to the display. If the variable is a **String** type, then then the data will be written as a string of characters. This is the most appropriate data type to use for text data that consists of printable characters. This method will also accept a **Byte** array of characters to be written to the virtual display.

Length

A numeric value which specifies the number of bytes to write. Its maximum value is $2^{31}-1 = 2147483647$. If a value is specified for this argument and it is greater than the actual size of the buffer, then the **Length** argument will be ignored and the entire contents of the buffer will be written. If the argument is omitted, then the maximum number of characters to write is determined by the size of the buffer.

Return Value

This method returns the number of bytes actually written to the display, or -1 if an error was encountered.

Remarks

The **Write** method copies the data in **Buffer** to the virtual display at the current cursor location. If the data contains control characters or escape sequences, they will be processed according the **Emulation** property setting.

Terminal Emulator Control Events

Event	Description
Change	This event occurs when the contents of a control has changed
Click	This event occurs when the user presses and releases a mouse button
DblClick	This event occurs when the user presses and releases a mouse button twice
KeyDown	This event occurs when a key is pressed
KeyMapped	This event occurs when a mapped key is pressed
KeyPress	This event occurs when a key is pressed and released
KeyUp	This event occurs when a key is released
MouseDown	This event occurs when a mouse button is pressed
MouseMove	This event occurs when the user moves the mouse
MouseUp	This event occurs when a mouse button is released
Resize	The Resize event is generated after the control has been resized

Change Event

The **Change** event is generated when the contents of a control has changed.

Syntax

Sub *object_Change*([*Index As Integer*])

Remarks

The **Change** event is generated when the contents of a control have changed and can be used to synchronize or coordinate data display among controls. For example, you can use the control's **Change** event to check for text at certain screen location and then a list box which contains that text.

Modifying the contents of the virtual display by setting the **Text** property or calling the **Write** method in the event handler can cause a cascading event. It is recommended that you only read, not modify, the contents of the virtual display when this even occurs.

See Also

[Resize Event](#)

Click Event

The **Click** event is generated when the user presses and releases a mouse button.

Syntax

Sub *object_Click*([*Index As Integer*])

Remarks

The **Click** event is generated when the user presses and releases the mouse button anywhere over the control's window. To distinguish between the user pressing the left or right mouse buttons, use the **MouseDown** and **MouseUp** events. To determine the column and row in the virtual display where the mouse button was clicked, check the **MouseX** and **MouseY** properties.

When debugging events, do not use message boxes to show when the event occurred, as this will interfere with the normal functioning of many events. For example, displaying a message box in the **Click** event may prevent the **DbClick** event from being raised.

See Also

[MouseX Property](#), [MouseY Property](#), [DbClick Event](#), [MouseDown Event](#), [MouseUp Event](#)

DbClick Event

The **DbClick** event is generated when the user presses and releases a mouse button twice.

Syntax

Sub *object_DbClick*([*Index As Integer*])

Remarks

The **DbClick** event is generated when the user presses and releases the mouse button, then quickly presses and releases the mouse button again, anywhere over the control's window. To distinguish between the user pressing the left or right mouse buttons, use the **MouseDown** and **MouseUp** events. To determine the column and row in the virtual display where the mouse button was clicked, check the **MouseX** and **MouseY** properties.

If the user doesn't double-click within the system's time limit, the control receives another **Click** event instead. The double-click time limit may vary because the user can set the double-click speed in the Control Panel. When you're attaching procedures for these related events, be sure that their actions don't conflict. Controls that don't receive **DbClick** events may receive two clicks instead of a double-click.

When debugging events, do not use message boxes to show when the event occurred, as this will interfere with the normal functioning of many events. For example, displaying a message box in the **Click** event may prevent the **DbClick** event from being raised.

See Also

[MouseX Property](#), [MouseY Property](#), [Click Event](#), [MouseDown Event](#), [MouseUp Event](#)

KeyDown Event

The **KeyDown** event is generated when a key is pressed.

Syntax

Sub *object_KeyDown*([*Index As Integer*], *KeyCode As Integer*, *Shift As Integer*)

Remarks

The **KeyDown** event is generated when the user presses a key on the keyboard. The following arguments are passed to the event handler:

KeyCode

A key code which identifies the key being pressed. If the key is a number or letter on the keyboard, then the code corresponds to its ASCII equivalent. For example, the key code for the 'A' key is 65. It is important to note that shift states are handled differently in that the key code is the same regardless if the shift or control key is being pressed at the same time. For keys other than numbers or letters, consult the [Virtual Key Constants](#) table.

Shift

An integer that corresponds to the state of the Shift, Ctrl, and Alt keys at the time the key is pressed. The **Shift** argument is a bit field with the least-significant bits corresponding to the Shift key (bit 0), the Ctrl key (bit 1), and the Alt key (bit 2). These bits correspond to the values 1, 2, and 4, respectively. Some, all, or none of the bits can be set, indicating that some, all, or none of the keys are pressed. For example, if both Ctrl and Alt keys are pressed, the value of **Shift** is 6.

See Also

[KeyMapped Event](#), [KeyPress Event](#), [KeyUp Event](#)

KeyMapped Event

The **KeyMapped** event is generated when a mapped key is pressed.

Syntax

```
Sub object_KeyMapped( [Index As Integer,] KeyIndex As Integer, Shift As Integer, KeyString As String )
```

Remarks

This event occurs when the user presses a special key while the emulation window has focus, and that key is mapped to a string using the KeyMap property array.

KeyIndex

An integer which specifies which mapped key was pressed, and is the same as the index value used with the **KeyMap** property array. Refer to the [KeyMap Constants](#) table for a list of keys and their corresponding values which may be mapped by the application. Note that the **KeyIndex** value is different than the key codes used by the **KeyDown** and **KeyUp** events.

Shift

An integer that corresponds to the state of the Shift, Ctrl, and Alt keys at the time the key is pressed. The **Shift** argument is a bit field with the least-significant bits corresponding to the Shift key (bit 0), the Ctrl key (bit 1), and the Alt key (bit 2). These bits correspond to the values 1, 2, and 4, respectively. Some, all, or none of the bits can be set, indicating that some, all, or none of the keys are pressed. For example, if both Ctrl and Alt keys are pressed, the value of **Shift** is 6.

KeyString

A string that contains the control and/or escape sequence that the key has been mapped to. This is the same value that was assigned to the **KeyMap** property array for this key.

Example

The following example demonstrates how to use the **KeyMapped** event in conjunction with the **SendKey** method in the Telnet control:

```
Private Sub Terminal1_KeyMapped(KeyIndex As Integer, Shift As Integer, KeyString As String)
    TelnetClient1.SendKey KeyString
End Sub
```

See Also

[KeyMap Property](#), [KeyDown Event](#), [KeyPress Event](#), [KeyUp Event](#)

KeyPress Event

The **KeyPress** event is generated when a key is pressed and released.

Syntax

```
Sub object_KeyPress( [Index As Integer], KeyAscii As Integer )
```

Remarks

The **KeyPress** event is generated when the user presses and releases key on the keyboard. The following arguments are passed to the event handler:

KeyAscii

An integer which specifies the standard ASCII value of the key that was pressed. In Visual Basic, you can convert the key value into a character by using the **Chr** function.

Example

The following example demonstrates how to use the **KeyPress** event in conjunction with the **SendKey** method in the Telnet control:

```
Private Sub Terminal1_KeyPress(KeyAscii As Integer)
    TelnetClient1.SendKey KeyAscii
End Sub
```

See Also

[KeyDown Event](#), [KeyMapped Event](#), [KeyUp Event](#)

KeyUp Event

The **KeyUp** event is generated when a key is released.

Syntax

Sub *object_KeyUp*([*Index As Integer*], *KeyCode As Integer*, *Shift As Integer*)

Remarks

The **KeyUp** event is generated when the user releases a previously pressed key. The following arguments are passed to the event handler:

KeyCode

A key code which identifies the key being released. If the key is a number or letter on the keyboard, then the code corresponds to its ASCII equivalent. For example, the key code for the 'A' key is 65. It is important to note that shift states are handled differently in that the key code is the same regardless if the shift or control key is being pressed at the same time. For keys other than numbers or letters, consult the [Virtual Key Constants](#) table.

Shift

An integer that corresponds to the state of the Shift, Ctrl, and Alt keys at the time the key is released. The **Shift** argument is a bit field with the least-significant bits corresponding to the Shift key (bit 0), the Ctrl key (bit 1), and the Alt key (bit 2). These bits correspond to the values 1, 2, and 4, respectively. Some, all, or none of the bits can be set, indicating that some, all, or none of the keys are pressed. For example, if both Ctrl and Alt keys are pressed, the value of **Shift** is 6.

[KeyDown Event](#), [KeyMapped Event](#), [KeyPress Event](#)

MouseDown Event

The **MouseDown** event is generated when a mouse button is pressed.

Syntax

Sub *object_MouseDown*([*Index As Integer*], *Button As Integer*, *Shift As Integer*, *X As Integer*, *Y As Integer*)

Remarks

The **MouseDown** event is generated when the user presses a button on the mouse. The following arguments are passed to the event handler:

Button

Returns an integer that identifies the button that was pressed to cause the event. The **Button** argument is a bit field with bits corresponding to the left button (bit 0), right button (bit 1), and middle button (bit 2). These bits correspond to the values 1, 2, and 4, respectively. Only one of the bits is set, indicating the button that caused the event.

Shift

An integer that corresponds to the state of the Shift, Ctrl, and Alt keys at the time the button is pressed. The **Shift** argument is a bit field with the least-significant bits corresponding to the Shift key (bit 0), the Ctrl key (bit 1), and the Alt key (bit 2). These bits correspond to the values 1, 2, and 4, respectively. Some, all, or none of the bits can be set, indicating that some, all, or none of the keys are pressed. For example, if both Ctrl and Alt keys are pressed, the value of **Shift** is 6.

X, Y

Returns the current location of the mouse pointer. The **X** and **Y** values are always expressed in terms of the coordinate system set by the container. To determine the current row and column where the mouse is positioned in the virtual display, use the **MouseX** and **MouseY** properties.

See Also

[MouseX Property](#), [MouseY Property](#), [MouseMove Event](#), [MouseUp Event](#)

MouseMove Event

The **MouseMove** event is generated when the user moves the mouse.

Syntax

Sub *object_MouseMove*([*Index As Integer*], *Button As Integer*, *Shift As Integer*, *X As Integer*, *Y As Integer*)

Remarks

The **MouseMove** event is generated when the user moves the mouse over the control window. The following arguments are passed to the event handler:

Button

Returns an integer that corresponds to the state of the mouse buttons when the mouse was moved. The **Button** argument is a bit field with bits corresponding to the left button (bit 0), right button (bit 1), and middle button (bit 2). These bits correspond to the values 1, 2, and 4, respectively. It indicates the complete state of the mouse buttons; some, all, or none of these three bits can be set, indicating that some, all, or none of the buttons are pressed.

Shift

An integer that corresponds to the state of the Shift, Ctrl, and Alt keys at the time the mouse was moved. The **Shift** argument is a bit field with the least-significant bits corresponding to the Shift key (bit 0), the Ctrl key (bit 1), and the Alt key (bit 2). These bits correspond to the values 1, 2, and 4, respectively. Some, all, or none of the bits can be set, indicating that some, all, or none of the keys are pressed. For example, if both Ctrl and Alt keys are pressed, the value of **Shift** is 6.

X, Y

Returns the current location of the mouse pointer. The **X** and **Y** values are always expressed in terms of the coordinate system set by the container. To determine the current row and column where the mouse is positioned in the virtual display, use the **MouseX** and **MouseY** properties.

See Also

[MouseX Property](#), [MouseY Property](#), [MouseDown Event](#), [MouseUp Event](#)

MouseUp Event

The **MouseUp** event is generated when a mouse button is released.

Syntax

Sub *object_MouseUp*([*Index As Integer*], *Button As Integer*, *Shift As Integer*, *X As Integer*, *Y As Integer*)

Remarks

The **MouseUp** event is generated when the user releases a previously pressed mouse button. The following arguments are passed to the event handler:

Button

Returns an integer that identifies the button that was released to cause the event. The **Button** argument is a bit field with bits corresponding to the left button (bit 0), right button (bit 1), and middle button (bit 2). These bits correspond to the values 1, 2, and 4, respectively. Only one of the bits is set, indicating the button that caused the event.

Shift

An integer that corresponds to the state of the Shift, Ctrl, and Alt keys at the time the button is released. The **Shift** argument is a bit field with the least-significant bits corresponding to the Shift key (bit 0), the Ctrl key (bit 1), and the Alt key (bit 2). These bits correspond to the values 1, 2, and 4, respectively. Some, all, or none of the bits can be set, indicating that some, all, or none of the keys are pressed. For example, if both Ctrl and Alt keys are pressed, the value of **Shift** is 6.

X, Y

Returns the current location of the mouse pointer. The **X** and **Y** values are always expressed in terms of the coordinate system set by the container. To determine the current row and column where the mouse is positioned in the virtual display, use the **MouseX** and **MouseY** properties.

Resize Event

The Resize event is generated after the control has been resized.

Syntax

Sub *object_Resize* ([*Index As Integer*])

Remarks

This event can be used to move or resize other controls when the control is resized. You can also use the Resize event to recalculate the width and/or height of controls that depend on the size of the control window.

nvtShiftF12	Shift F12 function key	nvtKeypad8	Numeric keypad 8
nvtEnter	Enter key	nvtKeypad9	Numeric keypad 9
nvtErase	Backspace key		

Virtual Key Constants

The following table lists the virtual key codes which are used by the [KeyDown](#), [KeyMapped](#) and [KeyUp](#) events. The constants listed are those that are defined by Visual Basic. If you are using another programming language, consult your technical reference documentation for more information about the constants used to define virtual key codes.

Value	Description
vbKeyLButton	Left mouse button
vbKeyRButton	Right mouse button
vbKeyMButton	Middle mouse button
vbKeyBack	Backspace key
vbKeyTab	Tab key
vbKeyReturn	Return or enter key
vbKeyShift	Shift key
vbKeyControl	Control key
vbKeyPause	Pause/Break key
vbKeyCaptial	Caps Lock key
vbKeyEscape	Escape key
vbKeySpace	Space key
vbKeyPageUp	Page Up key
vbKeyPageDown	Page Down key
vbKeyEnd	End key
vbKeyHome	Home key
vbKeyLeft	Left arrow key
vbKeyUp	Up arrow key
vbKeyRight	Right arrow key
vbKeyDown	Down arrow key
vbKeyPrint	Print key
vbKeyInsert	Insert key
vbKeyDelete	Delete key
vbKeyHelp	Help key
vbKeyNumpad0	Number pad 0 key
vbKeyNumpad1	Number pad 1 key
vbKeyNumpad2	Number pad 2 key
vbKeyNumpad3	Number pad 3 key

Value	Description
vbKeyNumpad5	Number pad 5 key
vbKeyNumpad6	Number pad 6 key
vbKeyNumpad7	Number pad 7 key
vbKeyNumpad8	Number pad 8 key
vbKeyNumpad9	Number pad 9 key
vbKeyMultiply	Number pad * key
vbKeyAdd	Number pad + key
vbKeySubtract	Number pad - key
vbKeyDecimal	Number pad decimal key
vbKeyDivide	Number pad / key
vbKeyF1	F1 key
vbKeyF2	F2 key
vbKeyF3	F3 key
vbKeyF4	F4 key
vbKeyF5	F5 key
vbKeyF6	F6 key
vbKeyF7	F7 key
vbKeyF8	F8 key
vbKeyF9	F9 key
vbKeyF10	F10 key
vbKeyF11	F11 key
vbKeyF12	F12 key
vbKeyF13	F13 key
vbKeyF14	F14 key
vbKeyF15	F15 key
vbKeyF16	F16 key
vbKeyNumlock	Num Lock key
vbKeyScrollLock	Scroll Lock key

vbKeyNumpad4	Number pad 4 key		

Text Message Control

Send text messages to a mobile communications device using a gateway service.

Reference

Control Information

Object Name	TextMessageCtl.TextMessage
File Name	CSTXTX12.OCX
Version	12.0.3024.1286
ProgID	SocketTools.TextMessage.12
ClassID	54893006-FB57-4324-8262-1E5758499C6F
Threading Model	Apartment
Help File	CST12CTL.CHM
Dependencies	None

Overview

Short Message Service (SMS) is a text messaging service used by mobile communication devices to exchange brief text messages. Most service providers also provide gateway servers that can be used to send messages to a wireless device on their network using standard email protocols. This ActiveX control provides methods that can be used to determine the provider associated with a specific telephone number and send a text message to the device using the provider's mail gateway.

The control has been designed to assist developers in sending text message notifications as part of their application. For example, it can be used to enable your software to automatically send notifications when a specific event occurs, such as an error condition. It is not designed to be used with software that will send out a large number of text messages to many users, and there are limitations on the number of messages that may be sent to different phone numbers over a short period of time. Because some recipients must pay a fee for each text message they receive, text messages should only be sent to those who explicitly request them.

Applications should use an alternate method for sending text messages. Most mobile carriers have shut down their email-to-SMS gateways, making this method of sending text messages unreliable or unavailable. It is recommended that you transition to dedicated SMS service providers, which deliver messages over HTTPS-based APIs instead of email.

Requirements

The SocketTools ActiveX Edition components are self-registering controls that are compatible with any programming language that supports the Component Object Model (COM) and the ActiveX control

specification. If you are using Visual Basic 6.0, Service Pack 6 (SP6) is required. We recommend installing all available updates for your development tools. Although the Visual Basic 6.0 runtime is supported on Windows 11, the IDE itself is no longer officially supported by Microsoft. Legacy IDEs and compilers may also require elevated (administrator) privileges to run properly.

The ActiveX controls are supported on Windows 7, Windows Server 2008 R2, and later versions of both desktop and server editions of Windows. For Windows 7, Service Pack 1 (SP1) is the minimum requirement. For Windows 8 systems, the 8.1 update must be installed. On ARM-based platforms, the minimum supported version is Windows 10 build 1709.

SocketTools includes components for both 32-bit (x86) and 64-bit (x64) Windows platforms. All modern versions of Windows are 64-bit, but we continue to include 32-bit components for compatibility with legacy development tools such as Visual Basic 6.0. We also provide native ARM64 ActiveX controls for systems running Windows on ARM. Note that 32-bit applications on ARM run using x86 emulation, and Microsoft no longer supports native ARM32 applications.

If you are using VBScript, Visual Basic for Applications (VBA), or another scripting environment on an ARM-based system, be aware that 64-bit hosts will require ARM64 components, while 32-bit hosts will use x86 components under emulation. This includes applications created with Visual Basic 6.0. To reduce deployment complexity and avoid confusion, SocketTools does not include ARM32 ActiveX controls in its standard redistribution packages but they are available on request for legacy or specialized scenarios.

Distribution

When you distribute an application that uses this control, you can either install the file in the same folder as your application executable or as a shared component in the appropriate system folder. If you install the control in the system folder, it is important that you distribute the correct version for the target platform and it must be registered. If you install the control in the same folder as your executable, it is recommended that you use registration-free activation or COM redirection to ensure that the correct version of the control is loaded by the application.

Text Message Control Properties

Property	Description
IsInitialized	Determine if the control has been initialized
LastError	Gets and sets the last error that occurred on the control
LastErrorString	Return a description of the last error to occur
Message	Gets and sets the current message text
Password	Gets and sets the password used to authenticate the session
PhoneNumber	Gets and sets the phone number for the mobile device
Provider	Gets and sets the name of the preferred wireless service provider
ProviderCount	Gets the number of supported wireless service providers
ProviderName	Gets the name of a supported wireless service provider
Relay	Enable or disable the use of an intermediate relay server to send messages
Secure	Enable or disable secure connections to the server
Sender	Gets and sets the value that identifies the sender of the message
ServerName	Gets and sets the name of the server that is used to send messages
ServerPort	Gets and sets the port number used to establish a connection
ServiceType	Gets and sets the type of service used to send messages
ThrowError	Enables or disables error handling by the application
Timeout	Gets and sets the amount of time until a blocking operation fails
Trace	Enable or disable socket function level tracing
TraceFile	Specify the socket function trace output file
Urgent	Enable or disable the option that flags a message as urgent
UserName	Gets and sets the user name or ID used to authenticate the session
Version	Gets the current version of the control

LastError Property

Gets and sets the last error that occurred on the control.

Syntax

object.LastError [= *value*]

Remarks

The **LastError** property can be read to determine the last error that occurred for this control. If a value is assigned to this property, it must either be zero to clear the error or a valid error code for the control.

Data Type

Integer (Int32)

See Also

[LastErrorString Property](#), [ThrowError Property](#), [OnError Event](#)

LastErrorString Property

Return a description of the last error to occur

Syntax

object.LastErrorString

Remarks

The **LastErrorString** property returns a description of the last error that occurred. This can be used to display a meaningful error message to a user, rather than just the numeric value returned by the **LastError** property.

Data Type

String

See Also

[LastError Property](#), [ThrowError Property](#), [OnError Event](#)

Message Property

Gets and sets the current message text.

Syntax

object.**Message** [= *value*]

Remarks

The **Message** property returns the current message text. Changing the value of this property will change the message text sent by the **SendMessage** method if no message is explicitly specified. In most cases, a message should not exceed 160 characters in length, although some service providers may accept longer messages. If a message exceeds the maximum number of characters accepted by a service provider, the message may be ignored or it may be split into multiple messages.

Data Type

String

See Also

[PhoneNumber Property](#), [Sender Property](#), [Urgent Property](#), [SendMessage Method](#)

Password Property

Gets and sets the password used to authenticate the session.

Syntax

object.Password [= *value*]

Remarks

The **Password** property is used to authenticate the current session. If the message is being sent using SMTP, this property is used to specify a password when connecting to the mail server . If no authentication is required, this property may be an empty string. Note that some service providers may use terminology other than "password" with their documentation; in that case, this property will always specify the second of a pair of authentication tokens sent to the server to identify the client.

Data Type

String

See Also

[ServerName Property](#), [ServerPort Property](#), [UserName Property](#), [SendMessage Method](#)

PhoneNumber Property

Gets and sets the phone number for the mobile device.

Syntax

object.**PhoneNumber** [= *value*]

Remarks

The **PhoneNumber** property returns the current phone number. Changing the value of this property will change the default phone number the **SendMessage** method will use when sending a message. This can be a standard E.164 formatted phone number or an unformatted number. Any extraneous whitespace, punctuation or other non-numeric characters in the string will be ignored.

Data Type

String

See Also

[Message Property](#), [Provider Property](#), [Sender Property](#), [SendMessage Method](#)

Provider Property

Gets and sets the name of the preferred wireless service provider.

Syntax

object.Provider [= *value*]

Remarks

The **Provider** property returns the preferred wireless service provider associated with the current phone number. Changing the value of this property will change the preferred wireless service provider. If this property is an empty string, the default provider assigned to the recipient's phone number will be used. This property is only used with messages sent using SMTP and is ignored for other message services.

In the United States and Canada, most wireless common carriers are required to provide wireless number portability (WNP) which allows a customer to continue to use their current phone number even if they switch to another service provider. This can result in a situation where a specific phone number is shown as allocated to one provider, but in actuality that user has switched to a different provider. For example, a user may have originally purchased a phone and service with AT&T and then later switched to Verizon, but decided to keep their phone number. In this case, if Verizon was not specified as the preferred provider, the library would attempt to send the message to the AT&T gateway, since that was the original provider who allocated the phone number.

For most applications, the correct way to handle the situation in which a user may have switched to a different service provider is to allow them to select a preferred provider in your user interface. For example, you could display a drop-down list of available providers for them to select from, populated using the **ProviderName** property array. If they select a preferred provider, then you would assign that value to this property. If they choose to use the default provider, set this property to an empty string.

Data Type

String

See Also

[ProviderCount Property](#), [ProviderName Property](#), [GetAddress Method](#), [GetProvider Method](#)

ProviderCount Property

Gets the number of supported wireless service providers.

Syntax

object.ProviderCount

Remarks

The **ProviderCount** property returns the number of wireless service providers supported by the control. This property is used in conjunction with the **ProviderName** property to enumerate all of the supported service providers. Typically this done to populate a user-interface control that enables the user to select a preferred service provider.

Data Type

Integer (Int32)

Example

```
With TextMessage1
    For nIndex = 0 To .ProviderCount - 1
        ComboBox1.AddItem .ProviderName(nIndex)
    Next
End With
```

See Also

[Provider Property](#), [ProviderName Property](#), [GetAddress Method](#), [GetProvider Method](#)

ProviderName Property

Gets the name of a supported wireless service provider.

Syntax

object.ProviderName(index)

Remarks

The **ProviderName** property array returns the name of supported wireless service provider. This property is used in conjunction with the **ProviderCount** property to enumerate all of the supported service providers. Typically this done to populate a user-interface control that enables the user to select a preferred service provider. The first provider name has an index value of zero. Specifying an invalid index value will cause the control to throw an exception.

Data Type

String

Example

```
With TextMessage1
    For nIndex = 0 To .ProviderCount - 1
        ComboBox1.AddItem .ProviderName(nIndex)
    Next
End With
```

See Also

[Provider Property](#), [ProviderCount Property](#), [GetAddress Method](#), [GetProvider Method](#)

Relay Property

Enable or disable the use of an intermediate relay server to send messages.

Syntax

object.Relay [= { True | False }]

Remarks

The **Relay** property is used to determine if the control will send the message directly to the wireless service provider's gateway server, or if the message will be relayed through another mail server. The default value for this property is False. Setting this property to True will cause the control to connect to the mail server specified by the **ServerName** property, authenticate the client session if necessary and then submit the message.

When a text message is sent using the SMTP service, the default action is to attempt to connect directly to the wireless service provider's gateway server. However, many residential Internet service providers (ISPs) do not permit their customers to connect to third-party mail servers and will block the outbound connection. Some wireless service providers may also reject messages that originate from residential IP addresses.

To resolve this issue, the developer should allow the user to specify an alternate mail server that will relay the message to the wireless service provider. For residential users, this will typically be the mail server provided by their ISP. For business users, this will usually be their corporate mail server. The **ServerName** and **ServerPort** properties are used to identify the relay server, and the **UserName** and **Password** properties provide the credentials to authenticate the client session.

Data Type

Boolean

See Also

[Password Property](#), [ServerName Property](#), [ServerPort Property](#), [UserName Property](#)

Secure Property

Enable or disable secure connections to the server.

Syntax

object.**Secure** [= { True | False }]

Remarks

The **Secure** property determines if a secure connection is established to the server. The default value for this property is False, which specifies that a standard connection to the server is used. To establish a secure connection, the application must set this property value to True prior to calling the **SendMessage** method.

This property is only used when sending a message through a relay server using the SMTP service. Messages that are sent directly to the wireless service provider's gateway do not use authentication and are not secure, regardless of the value of this property.

Data Type

Boolean

See Also

[Relay Property](#), [ServerName Property](#), [ServerPort Property](#), [SendMessage Method](#)

Sender Property

Gets and sets the value that identifies the sender of the message.

Syntax

object.Sender [= *value*]

Remarks

The **Sender** property returns the email address of the sender when the SMTP service is used to send the message. For other service types, this property typically specifies the phone number or shortcode associated with the sender. Assigning a value to this property will set the default sender when the **SendMessage** method is called.

Data Type

String

See Also

[Message Property](#), [PhoneNumber Property](#)

ServerName Property

Gets and sets the name of the server that is used to send messages.

Syntax

object.ServerName [= *value*]

Remarks

The **ServerName** property is used to specify an alternate server that is used to deliver messages. When the SMTP service is used, this property is used in conjunction with the **Relay** property to enable the relaying of messages through another mail server.

By default, the phone number is used to automatically determine the host name of the gateway server that is responsible for accepting messages for the mobile device. However, under some circumstances it may not be possible to send messages directly to the wireless service provider's gateway. For example, many Internet service providers (ISPs) require that customers relay all messages through their servers and block any attempt to establish a direct connection with another mail server. This property can be used to specify an alternate server that will be responsible for sending the message.

Data Type

String

See Also

[Relay Property](#), [ServerName Property](#), [ServerPort Property](#)

ServerPort Property

Gets and sets the port number used to establish a connection.

Syntax

object.ServerPort [= *value*]

Remarks

The **ServerPort** property defines the port number which is used to establish a connection with the server. This property is used in conjunction with the **ServerName** property to specify an alternate server which is responsible for delivering messages.

Data Type

Integer (Int32)

See Also

[Relay Property](#), [ServerName Property](#)

ServiceType Property

Gets and sets the type of service used to send messages.

Syntax

object.ServiceType [= *value*]

Remarks

The **ServiceType** property identifies the service used to send the text message. This property is provided for future expansion where different types of services may be used to send a message. Currently, the only service type that is supported is SMTP, where the message is sent through a gateway mail server.

The following values may be assigned to or returned by this property:

Value	Description
1	smsServiceSmtplib>The text message will be sent through the mail gateway for the specified service provider. This service uses SMTP to submit the message for delivery, either directly to the server provider's mail gateway server or through a relay server. This is the default service type.

Data Type

Integer (Int32)

See Also

[Message Property](#), [PhoneNumber Property](#), [Sender Property](#), [SendMessage Method](#)

ThrowError Property

Enables or disables error handling by the application.

Syntax

object.**ThrowError** [= { True | False }]

Remarks

Error handling for methods can be performed using either return codes or exceptions, depending on the value of this property.

If the **ThrowError** property is set to False, methods will return a status value indicating success or failure. Applications should check the return value of each method and use the **LastError** and **LastErrorString** properties to determine the cause of any error.

If the **ThrowError** property is set to True, errors occurring within the control will be raised to the host application as ActiveX exceptions. In addition, the **OnError** event will fire. This allows applications to use language-specific exception handling mechanisms, such as Visual Basic error handling, instead of checking individual return values after each method call.

Even when the **ThrowError** property is set to True, the **LastError** and **LastErrorString** properties will still be updated with information about the most recent error.

If an error occurs while accessing a property value, an exception will be raised regardless of the value of the **ThrowError** property. However, the **OnError** event will not be fired for property access errors.

Data Type

Boolean

Example

The following example handles errors by checking the return code of a method:

```
TextMessage1.ThrowError = False
nError = TextMessage1.SendMessage()

If nError > 0 Then
    MsgBox TextMessage1.LastErrorString, vbExclamation
    Exit Sub
End If
```

The following example handles errors by throwing them to the container:

```
On Error Resume Next: Err.Clear

TextMessage1.ThrowError = True
TextMessage1.SendMessage

If Err.Number <> 0
    MsgBox Err.Description, vbExclamation
    Exit Sub
End If
On Error GoTo 0
```

See Also

[LastError Property](#), [LastErrorString Property](#), [OnError Event](#)

Timeout Property

Gets and sets the amount of time until a blocking operation fails.

Syntax

object.Timeout [= *seconds*]

Remarks

Setting the **Timeout** property specifies the number of seconds until a blocking operation fails and the control returns an error. This includes the amount of time the control will spend attempting to connect to a server and if the connection is not established within the given time period, the connection attempt will fail.

Data Type

Integer (Int32)

See Also

[SendMessage Method](#)

Trace Property

Enable or disable network function level logging.

Syntax

`object.Trace` [= { True | False }]

Remarks

The **Trace** property is used to enable or disable the logging of network function calls. When enabled, each function call is logged to a file, including the function parameters, return value and error code if applicable. This facility can be enabled and disabled at run time, and the trace log file can be specified by setting the **TraceFile** property. All function calls that are being logged are appended to the trace file, if it exists. If no log file exists when tracing is enabled, the file is created.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

Data Type

Boolean

See Also

[TraceFile Property](#), [TraceFlags Property](#)

TraceFile Property

Gets and sets the name of the file to use when logging network function calls.

Syntax

`object.TraceFile [= filename ]`

Remarks

The **TraceFile** property is used to specify the name of the file that is created when logging is enabled. If this property is set to an empty string (the default value), then a file named **SocketTools.log** is created in the current user's Documents folder. It is recommended that you always specify a complete path to the log file. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

If the file exists, the output is appended to the file, otherwise the file is created. Since logging is enabled per-process, the log file is shared by all instances of the controls being used. If you create multiple instances of the control, you only need to enable logging for a single instance. Because log files can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "0x". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxx:xxxx:xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, the control is attempting to connect to a system with the IPv4 address 192.0.0.1 on port 1234.

If the log file cannot be created, or the user does not have permission to modify an existing file, the error is silently ignored and no output will be generated.

Data Type

String

See Also

TraceFlags Property

Gets and sets the network function logging flags.

Syntax

`object.TraceFlags [= flags ]`

Remarks

The **TraceFlags** property is used to specify the type of information written to the trace file when socket function tracing is enabled. The following values may be used:

Value	Description
dnsTraceInfo	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
dnsTraceError	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
dnsTraceWarning	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
dnsTraceHexDump	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
dnsTraceTruncate	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.

Since logging is enabled per-process, the trace flags are shared by all instances of the control being used. If multiple controls have tracing enabled, the **TraceFlags** property should be set to the same value for each control. Changing the trace flags for any one instance of the control will affect the logging performed for all other instances used by the application.

Warnings are generated when a non-fatal error is returned by a Windows Sockets function. For example, if data is being written through the control and an error indicating that the operation would block is returned, only a warning is logged since the application simply needs to attempt to write the data at a later time.

Data Type

Integer (Int32)

See Also

[Trace Property](#), [TraceFile Property](#)

Urgent Property

Enable or disable the option that flags a message as urgent.

Syntax

`object.Urgent` [= { True | False }]

Remarks

The **Urgent** property specifies whether a message will be flagged as urgent or not. If this property is set to True, the message will sent with a high priority. Note that this does not guarantee the message will be received any differently than a standard text message. Each wireless service provider may handle urgent messages differently, and some providers may simply ignore the message priority. By default, this property is False.

Data Type

Boolean

See Also

[Message Property](#), [SendMessage Method](#)

UserName Property

Gets and sets the user name or ID used to authenticate the session.

Syntax

object.UserName [= *value*]

Remarks

The **UserName** property is used to authenticate the current session. If the message is being sent using SMTP, this property is used to specify a user name when connecting to the mail server . If no authentication is required, this property may be an empty string. Note that some service providers may use terminology other than "username" with their documentation; in that case, this property will always specify the first of a pair of authentication tokens sent to the server to identify the client.

Data Type

String

See Also

[Password Property](#), [ServerName Property](#), [ServerPort Property](#), [SendMessage Method](#)

Version Property

Return the current version of the control.

Syntax

object.Version

Remarks

The **Version** property returns the current version of the object. This can be used by an application for validation purposes. The version returned is composed of four numbers, separated by periods. The first number is the major version number, the second number is the minor version number, the third is the build number and the fourth is the revision number.

Data Type

String

Text Message Control Methods

Method	Description
GetAddress	Get the email address associated with the specified phone number
GetProvider	Get the name of the wireless service provider associated with a phone number
Initialize	Initialize the control and validate the runtime license key
Reset	Reset the internal state of the control
SendMessage	Send a text message to the specified mobile device
Uninitialize	Uninitialize the control and release any system resources that were allocated

GetAddress Method

Get the email address associated with the specified phone number.

Syntax

object.GetAddress(*PhoneNumber*, *Address*)

Parameters

PhoneNumber

A string value which specifies the phone number of the mobile device. This can be a standard E.164 formatted number or an unformatted number. Any extraneous whitespace, punctuation or other non-numeric characters in the string will be ignored.

Address

A string that will contain the email address associated with the specified phone number when the method returns. A mail message sent to this address will be forwarded to the mobile device as a text message. This parameter must be passed by reference.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure. If the method fails, the value of the **LastError** property can be used to determine cause of the failure.

Remarks

The **GetAddress** method can be used to determine if a phone number is associated with a mobile device and obtain the email address for the wireless service provider's gateway. This is done by sending an query to a server that will check the phone number against a database of known providers and the phone numbers that have been allocated for wireless devices.

By default, this method will attempt to automatically determine which service provider is associated with the phone number. If the service provider cannot be determined, this method will fail and return an error code. If the **Provider** property has been set to to the name of a specific service provider, that provider will be used to determine the gateway email address.

This method sends an HTTP query to the server **api.sockettools.com** to obtain information about the phone number and wireless service provider. This requires that the local system can establish a standard network connection over port 80. If the client cannot connect to the server, the method will fail and an appropriate error will be returned. The server imposes a limit on the maximum number of connections that can be established and the maximum number of requests that can be issued per minute. If this method is called multiple times over a short period, the control may also force the application to block briefly. Server responses are cached per session, so calling this method multiple times using the same phone number will not increase the request count.

See Also

[Provider Property](#), [ProviderCount Property](#), [ProviderName Property](#), [GetProvider Method](#), [SendMessage Method](#)

GetProvider Method

Get the name of the wireless service provider associated with a phone number.

Syntax

object.GetProvider(*PhoneNumber*, *ProviderName*)

Parameters

PhoneNumber

A string value which specifies the phone number of the mobile device. This can be a standard E.164 formatted number or an unformatted number. Any extraneous whitespace, punctuation or other non-numeric characters in the string will be ignored.

ProviderName

A string that will contain the name of the wireless service provider associated with the specified phone number when the method returns. This parameter must be passed by reference.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure. If the method fails, the value of the **LastError** property can be used to determine cause of the failure.

Remarks

The **GetProvider** method can be used to determine if a phone number is associated with a mobile device and obtain the name of the service provider associated with the number. This is done by sending an query to a server that will check the phone number against a database of known providers and the phone numbers that have been allocated for wireless devices.

This method sends an HTTP query to the server **api.sockettools.com** to obtain information about the phone number and wireless service provider. This requires that the local system can establish a standard network connection over port 80. If the client cannot connect to the server, the method will fail and an appropriate error will be returned. The server imposes a limit on the maximum number of connections that can be established and the maximum number of requests that can be issued per minute. If this method is called multiple times over a short period, the control may also force the application to block briefly. Server responses are cached per session, so calling this method multiple times using the same phone number will not increase the request count.

See Also

[Provider Property](#), [ProviderCount Property](#), [ProviderName Property](#), [GetAddress Method](#), [SendMessage Method](#)

Initialize Method

Initialize the control and validate the runtime license key.

Syntax

```
object.Initialize( [LicenseKey] )
```

Parameters

LicenseKey

An optional string which specifies a runtime license key used to initialize the control. If the license key is omitted or passed as an empty string, a development license must be installed on the local system.

Return Value

A value of zero is returned if the control was initialized successfully. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

This method dynamically loads other system libraries and allocates thread local storage. In most cases, it is not necessary to call this method directly because it is automatically invoked when an instance of the control is created by the container. However, if the control is created dynamically using **CreateObject** or a similar method, this must be the first method that is called before you attempt to modify any property values or invoke other methods. Failure to initialize the control may result in subsequent errors and/or cause an exception to be raised.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the control will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the control was created.

If the control is being used within another DLL, it is important that you do not attempt to create an instance of the control or call the **Initialize** method from within the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is written in C++ and it is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for any static and global C++ objects and has the same restrictions.

Example

```
Set smsClient = CreateObject("SocketTools.TextMessage.12")

nError = smsClient.Initialize(strLicenseKey)
If nError > 0 Then
    MsgBox "Unable to initialize SocketTools component"
End
End If
```

See Also

[IsInitialized Property](#), [Uninitialize Method](#)

Reset Method

Reset the internal state of the control.

Syntax

object.Reset

Parameters

None.

Return Value

None.

Remarks

The **Reset** method resets the internal state of the control. Property values are initialized to their internal defaults, open network connections will be closed and any handles allocated by the control will be released.

See Also

[Initialize Method](#), [Uninitialize Method](#)

SendMessage Method

Send a text message to the specified mobile device.

Syntax

```
object.SendMessage( [PhoneNumber, ] [Sender, ] [Message, ] [Options] )
```

Parameters

PhoneNumber

An optional string value which specifies the phone number of the mobile device. This can be a standard E.164 formatted number or an unformatted number. Any extraneous whitespace, punctuation or other non-numeric characters in the string will be ignored. If this parameter is omitted, the current value of the **PhoneNumber** property will be used.

Sender

An optional string value that identifies the sender of the message. For messages being sent using SMTP, this should be a valid email address. If this parameter is omitted, the current value of the **Sender** property will be used.

Message

An optional string value that contains the text message that will be sent. If this parameter is omitted, the current value of the **Message** property will be used.

Options

An optional integer value that is reserved for future use. If it is specified, it should have a value of zero.

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure. If the method fails, the value of the **LastError** property can be used to determine cause of the failure.

Remarks

The **SendMessage** method is used to send a text message to the specified mobile device. This control is designed to support multiple methods of sending text messages, with the **ServiceType** property determining how the message is sent:

smsServiceSmtplib

This message service sends the message through the wireless service provider's mail gateway using the SMTP protocol. However, it is important to note that many of these gateways will not accept messages from a client that is connected to them using a residential Internet service provider. If the application is being run on a system that uses a residential provider, that service provider may also block outbound connections to all mail servers other than their own. These anti-spam measures typically require that most end-user applications specify a relay mail server rather than submitting the message directly to the wireless provider's gateway.

By default, this method will attempt to automatically determine which service provider is associated with the phone number. If the service provider cannot be determined, this method will fail and return an error code. If the **Provider** property has been set to the name of a specific service provider, that provider will be used to determine the gateway email address.

Because most wireless carriers in the United States and Canada must provide for wireless number

portability, there is the possibility that the provider information returned may no longer correspond to the telephone number. It is recommended that you provide your end-user with the ability to specify an alternate preferred provider to use when sending the text message. For more information, refer to **ProviderCount** and **ProviderName** properties.

This method sends an HTTP query to the server **api.sockettools.com** to obtain information about the phone number and wireless service provider. This requires that the local system can establish a standard network connection over port 80. If the client cannot connect to the server, the method will fail and an appropriate error will be returned. The server imposes a limit on the maximum number of connections that can be established and the maximum number of requests that can be issued per minute. If this method is called multiple times over a short period, the control may also force the application to block briefly. Server responses are cached per session, so calling this method multiple times using the same phone number will not increase the request count.

Uninitialize Method

Uninitialize the control and release any system resources that were allocated.

Syntax

object.Uninitialize

Parameters

None.

Return Value

None.

Remarks

The **Uninitialize** method terminates any connection established by the control and resets the internal state of the control. This method is not typically used because any resources that have been allocated by an instance of the control will automatically be released when it is destroyed.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the control will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the control was created. An application should only call the **Uninitialize** method if it has explicitly called the **Initialize** method.

See Also

[Initialize Method](#)

Text Message Control Events

Event	Description
OnError	This event occurs when a control error occurs

OnError Event

The **OnError** event is generated when a control error occurs.

Syntax

```
Sub object_OnError ( [Index As Integer,] ByVal ErrorCode As Variant, ByVal Description As Variant )
```

Remarks

This event occurs when an error occurs during a control action. Errors not generated by the control itself, such as errors related to the programming language or general component errors, do not trigger this event.

The ***ErrorCode*** argument specifies the last error that has occurred. If the error is network related, the error code values returned by the control correspond to those returned by the standard Windows Sockets library.

The ***Description*** argument is a string that describes the error.

Control Information

Object Name	TimeClientCtl.TimeClient
File Name	CSTIMX12.OCX
Version	12.0.3024.1286
ProgID	SocketTools.TimeClient.12
ClassID	F7F8B645-126C-423F-BAD5-AC35AE7F6A39
Threading Model	Apartment
Help File	CST12CTL.CHM
Dependencies	None
Standards	RFC 868, RFC 5905

Overview

The Network Time Protocol control provides an interface for obtaining the current date and time from a server. The time is returned in Coordinated Universal Time (UCT) and can be adjusted for the local host's timezone. The time value is returned as the number of seconds which have elapsed since midnight, January 1, 1900. The control supports the Network Time Protocol (NTP) as specified in RFC 5905 and the TIME protocol described in RFC 868.

The values used by the ActiveX control are 32-bit integers which will rollover on February 7, 2036.

Requirements

The SocketTools ActiveX Edition components are self-registering controls that are compatible with any programming language that supports the Component Object Model (COM) and the ActiveX control specification. If you are using Visual Basic 6.0, Service Pack 6 (SP6) is required. We recommend installing all available updates for your development tools. Although the Visual Basic 6.0 runtime is supported on Windows 11, the IDE itself is no longer officially supported by Microsoft. Legacy IDEs and compilers may also require elevated (administrator) privileges to run properly.

The ActiveX controls are supported on Windows 7, Windows Server 2008 R2, and later versions of both desktop and server editions of Windows. For Windows 7, Service Pack 1 (SP1) is the minimum requirement. For Windows 8 systems, the 8.1 update must be installed. On ARM-based platforms, the minimum supported version is Windows 10 build 1709.

SocketTools includes components for both 32-bit (x86) and 64-bit (x64) Windows platforms. All

modern versions of Windows are 64-bit, but we continue to include 32-bit components for compatibility with legacy development tools such as Visual Basic 6.0. We also provide native ARM64 ActiveX controls for systems running Windows on ARM. Note that 32-bit applications on ARM run using x86 emulation, and Microsoft no longer supports native ARM32 applications.

If you are using VBScript, Visual Basic for Applications (VBA), or another scripting environment on an ARM-based system, be aware that 64-bit hosts will require ARM64 components, while 32-bit hosts will use x86 components under emulation. This includes applications created with Visual Basic 6.0. To reduce deployment complexity and avoid confusion, SocketTools does not include ARM32 ActiveX controls in its standard redistribution packages but they are available on request for legacy or specialized scenarios.

Distribution

When you distribute an application that uses this control, you can either install the file in the same folder as your application executable or as a shared component in the appropriate system folder. If you install the control in the system folder, it is important that you distribute the correct version for the target platform and it must be registered. If you install the control in the same folder as your executable, it is recommended that you use registration-free activation or COM redirection to ensure that the correct version of the control is loaded by the application.

Network Time Protocol Control Properties

Property	Description
AutoResolve	Determines if host names and IP addresses are automatically resolved
HostAddress	Gets and sets the IP address of the server
HostName	Gets and sets the name of the server
Interval	Gets and sets the timer interval in milliseconds
IsBlocked	Return if the control is blocked performing an operation
IsInitialized	Determine if the control has been initialized
LastError	Gets and sets the last error that occurred on the control
LastErrorString	Return a description of the last error to occur
LocalDate	Returns the network date adjusted for the local timezone
LocalTime	Returns the network time adjusted for the local timezone
RemotePort	Gets and sets the port number for a remote connection
SystemDate	Returns the network date adjusted for the local timezone
SystemTime	Returns the network time adjusted for the local timezone
Timeout	Gets and sets the amount of time until a blocking operation fails
Trace	Enable or disable socket function level tracing
TraceFile	Specify the socket function trace output file
TraceFlags	Gets and sets the socket function tracing flags
Version	Return the current version of the control

AutoResolve Property

Determines if host names and IP addresses are automatically resolved.

Syntax

object.AutoResolve [= { True | False }]

Remarks

Setting the **AutoResolve** property determines if the control automatically resolves host names and addresses specified by the **HostName** and **HostAddress** properties. If set to True, setting the **HostName** property will cause the control to automatically determine the corresponding IP address and set the **HostAddress** property accordingly. Likewise, setting the **HostAddress** property will cause the control to determine the host name and set the **HostName** property. Setting the property to False prevents the control from resolving host names until a connection attempt is made.

Note that setting the **HostName** or **HostAddress** property may cause the current thread to block, sometimes for several seconds, until the name or address is resolved. To prevent this behavior, set **AutoResolve** to False.

Data Type

Boolean

See Also

[HostAddress Property](#), [HostName Property](#)

HostAddress Property

Gets and sets the IP address of the server.

Syntax

object.HostAddress [= *ipaddress*]

Remarks

The **HostAddress** property can be used to set the IP address for a server that you wish to communicate with. If the address is valid and matches an entry in the host table, the **HostName** property will be changed to match the address.

Data Type

String

See Also

[AutoResolve Property](#), [HostName Property](#)

HostName Property

Gets and sets the name of the server.

Syntax

object.HostName [= *hostname*]

Remarks

The **HostName** property should be set to the name of the server that you wish to communicate with. If the name is found in the host table, the **HostAddress** property is updated to reflect the IP address of the host.

Note that it is legal to assign an IP address to this property, but it is not legal to assign a host name to the **HostAddress** property.

Data Type

String

See Also

[AutoResolve Property](#), [HostAddress Property](#)

Interval Property

Gets and sets the timer interval in milliseconds.

Syntax

object.Interval [= *milliseconds*]

Remarks

The **Interval** property specifies the number of milliseconds between calls to the **Timer** event. A value of zero indicates that the timer is disabled and no events will be generated. The maximum interval value is 65536 milliseconds, which is slightly more than one minute.

Data Type

Integer (Int32)

See Also

[Timer Event](#)

IsBlocked Property

Return if the control is blocked performing an operation.

Syntax

object.IsBlocked

Remarks

The **IsBlocked** property returns True if the specified control is blocked performing an operation. Because the Windows Sockets API only permits one blocking operation per thread of execution, this property should be checked before starting any blocking operation.

Note that this property will return True if there is *any* blocking operation being performed by the application, regardless if the specified control is responsible for the blocking operation or not.

Data Type

Boolean

See Also

[LastError Property](#)

LastError Property

Gets and sets the last error that occurred on the control.

Syntax

object.LastError [= *value*]

Remarks

The **LastError** property can be read to determine the last error that occurred for this control. If a value is assigned to this property, it must either be zero to clear the error or a valid error code for the control.

Data Type

Integer (Int32)

See Also

[LastErrorString Property](#), [OnError Event](#)

LastErrorString Property

Return a description of the last error to occur.

Syntax

object.LastErrorString

Remarks

The **LastErrorString** property returns a description of the last error that occurred. This can be used to display a meaningful error message to a user, rather than just the numeric value returned by the **LastError** property.

Data Type

String

See Also

[LastError Property](#), [OnError Event](#)

LocalDate Property

Returns the network date adjusted for the local timezone.

Syntax

object.**LocalDate**

Remarks

The **LocalDate** property returns the network date and adjusts the value for the local timezone. The date is returned as a string formatted using the Short Date format for the current locale.

Data Type

String

See Also

[LocalTime Property](#), [SystemDate Property](#), [SystemTime Property](#), [GetTime Method](#), [SetTime Method](#)

LocalTime Property

Returns the network time adjusted for the local timezone.

Syntax

object.LocalTime

Remarks

The **LocalTime** property returns the network time and adjusts the value for the local timezone. The time is returned as a string formatted using the standard format for the current locale.

Data Type

String

See Also

[LocalDate Property](#), [SystemDate Property](#), [SystemTime Property](#), [GetTime Method](#), [SetTime Method](#)

RemotePort Property

Gets and sets the port number for a remote connection.

Syntax

object.RemotePort [= *portnumber*]

Remarks

The **RemotePort** property is used to set the port number that the control will use to establish a connection with the server.

Data Type

Integer (Int32)

See Also

[HostAddress Property](#), [HostName Property](#)

SystemDate Property

Returns the network date adjusted for the local timezone.

Syntax

object.SystemDate

Remarks

The **SystemDate** property returns the network date in Coordinated Universal Time (UTC). The date is returned as a string formatted using the Short Date format for the current locale.

Data Type

String

See Also

[LocalDate Property](#), [LocalTime Property](#), [SystemTime Property](#), [GetTime Method](#)

SystemTime Property

Returns the network time adjusted for the local timezone.

Syntax

object.LocalTime

Remarks

The **SystemTime** property returns the network time in Coordinated Universal Time (UTC). The time is returned as a string formatted using the standard format for the current locale.

Data Type

String

See Also

[LocalDate Property](#), [LocalTime Property](#), [SystemDate Property](#), [GetTime Method](#), [SetTime Method](#)

ThrowError Property

Enables or disables error handling by the application.

Syntax

object.ThrowError = { True | False }

Remarks

Error handling for methods can be performed using either return codes or exceptions, depending on the value of this property.

If the **ThrowError** property is set to False, methods will return a status value indicating success or failure. Applications should check the return value of each method and use the **LastError** and **LastErrorString** properties to determine the cause of any error.

If the **ThrowError** property is set to True, errors occurring within the control will be raised to the host application as ActiveX exceptions. In addition, the **OnError** event will fire. This allows applications to use language-specific exception handling mechanisms, such as Visual Basic error handling, instead of checking individual return values after each method call.

Even when the **ThrowError** property is set to True, the **LastError** and **LastErrorString** properties will still be updated with information about the most recent error.

If an error occurs while accessing a property value, an exception will be raised regardless of the value of the **ThrowError** property. However, the **OnError** event will not be fired for property access errors.

Data Type

Boolean

Example

The following example handles errors by checking the return code of a method:

```
TimeClient1.ThrowError = False
strValue = TimeClient1.GetTime(strHostName)

If Len(strValue) = 0 Then
    MsgBox TimeClient1.LastErrorString, vbExclamation
    Exit Sub
End If
```

The following example handles errors by throwing them to the container:

```
On Error Resume Next: Err.Clear

TimeClient1.ThrowError = True
strValue = TimeClient1.GetTime(strHostName)

If Err.Number <> 0
    MsgBox Err.Description, vbExclamation
    Exit Sub
End If
On Error GoTo 0
```

See Also

[LastError Property](#), [LastErrorString Property](#), [OnError Event](#)

Timeout Property

Gets and sets the amount of time until a blocking operation fails.

Syntax

object.Timeout [= *seconds*]

Remarks

Setting the **Timeout** property specifies the number of seconds until a blocking operation fails and the control returns an error.

Note that the **Timeout** property also determines the amount of time the control will spend attempting to connect to a server. If a connection is not established within the given time period, the connection attempt will fail.

Data Type

Integer (Int32)

Trace Property

Enable or disable network function level logging.

Syntax

`object.Trace [= { True | False } ]`

Remarks

The **Trace** property is used to enable or disable the logging of network function calls. When enabled, each function call is logged to a file, including the function parameters, return value and error code if applicable. This facility can be enabled and disabled at run time, and the trace log file can be specified by setting the **TraceFile** property. All function calls that are being logged are appended to the trace file, if it exists. If no log file exists when tracing is enabled, the file is created.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

Data Type

Boolean

See Also

[TraceFile Property](#), [TraceFlags Property](#)

TraceFile Property

Gets and sets the name of the file to use when logging network function calls.

Syntax

`object.TraceFile [= filename ]`

Remarks

The **TraceFile** property is used to specify the name of the file that is created when logging is enabled. If this property is set to an empty string (the default value), then a file named **SocketTools.log** is created in the current user's Documents folder. It is recommended that you always specify a complete path to the log file. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

If the file exists, the output is appended to the file, otherwise the file is created. Since logging is enabled per-process, the log file is shared by all instances of the controls being used. If you create multiple instances of the control, you only need to enable logging for a single instance. Because log files can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "0x". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxx:xxxx:xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, the control is attempting to connect to a system with the IPv4 address 192.0.0.1 on port 1234.

If the log file cannot be created, or the user does not have permission to modify an existing file, the error is silently ignored and no output will be generated.

Data Type

String

See Also

TraceFlags Property

Gets and sets the network function logging flags.

Syntax

`object.TraceFlags [= flags ]`

Remarks

The **TraceFlags** property is used to specify the type of information written to the trace file when socket function tracing is enabled. The following values may be used:

Value	Description
dnsTraceInfo	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
dnsTraceError	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
dnsTraceWarning	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
dnsTraceHexDump	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
dnsTraceTruncate	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.

Since logging is enabled per-process, the trace flags are shared by all instances of the control being used. If multiple controls have tracing enabled, the **TraceFlags** property should be set to the same value for each control. Changing the trace flags for any one instance of the control will affect the logging performed for all other instances used by the application.

Warnings are generated when a non-fatal error is returned by a Windows Sockets function. For example, if data is being written through the control and an error indicating that the operation would block is returned, only a warning is logged since the application simply needs to attempt to write the data at a later time.

Data Type

Integer (Int32)

See Also

[Trace Property](#), [TraceFile Property](#)

Version Property

Return the current version of the control.

Syntax

object.Version

Remarks

The **Version** property returns the current version of the object. This can be used by an application for validation purposes. The version returned is composed of four numbers, separated by periods. The first number is the major version number, the second number is the minor version number, the third is the build number and the fourth is the revision number.

Data Type

String

Network Time Protocol Control Methods

Method	Description
Cancel	Cancels the current blocking network operation
GetTime	Obtain the current system date and time
Initialize	Initialize the control and validate the runtime license key
Reset	Reset the internal state of the control
SetTime	Set the local system clock to the value returned by the network time server
Uninitialize	Uninitialize the control and release any system resources that were allocated

Cancel Method

Cancels the current blocking network operation.

Syntax

object.Cancel

Parameters

None.

Return Value

None.

Remarks

The **Cancel** method cancels any blocking network operation in the current thread. This is typically used inside an event handler, causing the blocking method to return to the caller with an error indicating that the current operation was canceled. This method sets an internal flag that is periodically checked during a blocking operation, such as waiting for more data to arrive. If the current thread is not blocked at the time that this method is called, it will have no effect.

See Also

[Reset Method](#)

GetTime Method

Obtain the current system date and time.

Syntax

object.GetTime([*RemoteHost*], [*RemotePort*], [*Timeout*], [*Localize*])

Parameters

RemoteHost

A string which specifies the host name or IP address of the server. If this argument is not specified, it defaults to the value of the **HostAddress** property if it is defined. Otherwise, it defaults to the value of the **HostName** property.

RemotePort

A number which specifies the port to connect to on the server. If this argument is not specified, it defaults to the value of the **RemotePort** property. A value of zero indicates that the default port number for this service should be used to establish the connection.

Timeout

The number of seconds that the client will wait for a response before failing the operation. If this argument is not specified, the value of the **Timeout** property will be used as the default.

Localize

A boolean argument which specifies if the time should be localized to the timezone on the current system. If the value is True, then the time returned by the server will be adjusted so that it reflects the current time in the local timezone. If this argument is omitted or a value of false is passed to the method, the date and time are returned in Coordinated Universal Time (UTC).

Return Value

The time and date retrieved from the server will be returned as a string formatted according to the user's current locale. If the date could not be retrieved, an empty string will be returned. To determine the cause of the failure, check the value of the **LastError** property.

Remarks

The **GetTime** method causes the control to connect to the specified server and request the current date and time. The application will block and wait for a response until the timeout period is reached. In most cases, it is preferable to use the NTP pool servers which distribute requests over a number of different servers:

- **pool.ntp.org** is a global load-balanced pool of time servers
- **us.pool.ntp.org** servers are located in the United States
- **eu.pool.ntp.org** servers are located in Europe
- **asia.pool.ntp.org** servers are located in Asia

There are also load balanced pools of time servers available in specific countries prefixed by their country code. For example, the **de.pool.ntp.org** servers are located in Germany and the **uk.pool.ntp.org** servers are located in the United Kingdom. Regardless of their location, the time values they return are always in Coordinated Universal Time (UTC) and are not localized based on the physical location of the server.

In the United States, the National Institute of Standards and Technology (NIST) hosts a number of

public servers which can be used to obtain the current time. The following table lists the current host names and addresses:

Server Name	IP Address	Location
time-a.nist.gov	129.6.15.28	Gaithersburg, Maryland
time-b.nist.gov	129.6.15.29	Gaithersburg, Maryland
time-nw.nist.gov	131.107.13.100	Redmond, Washington
time-a.timefreq.bldrdoc.gov	132.163.4.101	Boulder, Colorado
time-b.timefreq.bldrdoc.gov	132.163.4.102	Boulder, Colorado
time-c.timefreq.bldrdoc.gov	132.163.4.103	Boulder, Colorado

Time servers are also commonly maintained by Internet service providers and universities. If you are unable to obtain the time from a server, contact the system administrator to determine if they have the standard time service available on port 123.

See Also

[LocalDate Property](#), [LocalTime Property](#), [SystemDate Property](#), [SystemTime Property](#), [SetTime Method](#)

Initialize Method

Initialize the control and validate the runtime license key.

Syntax

```
object.Initialize( [LicenseKey] )
```

Parameters

LicenseKey

An optional string value which specifies a runtime license key used to initialize the control. If the license key is omitted or passed as an empty string, a development license must be installed on the local system.

Return Value

A value of zero is returned if the control was initialized successfully. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

This method dynamically loads other system libraries and allocates thread local storage. In most cases, it is not necessary to call this method directly because it is automatically invoked when an instance of the control is created by the container. However, if the control is created dynamically using **CreateObject** or a similar method, this must be the first method that is called before you attempt to modify any property values or invoke other methods. Failure to initialize the control may result in subsequent errors and/or cause an exception to be raised.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the control will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the control was created.

If the control is being used within another DLL, it is important that you do not attempt to create an instance of the control or call the **Initialize** method from within the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is written in C++ and it is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for any static and global C++ objects and has the same restrictions.

Example

```
Set timeClient = CreateObject("SocketTools.TimeClient.12")

nError = timeClient.Initialize(strLicenseKey)
If nError > 0 Then
    MsgBox "Unable to initialize SocketTools component"
End
End If
```

See Also

[IsInitialized Property](#), [Uninitialize Method](#)

Reset Method

Reset the internal state of the control.

Syntax

object.Reset

Parameters

None.

Return Value

None.

Remarks

The **Reset** method resets the internal state of the control. Property values are initialized to their internal defaults, open network connections will be closed and any handles allocated by the control will be released.

See Also

[Cancel Method](#), [Initialize Method](#), [Uninitialize Method](#)

SetTime Method

Set the local system clock to the value returned by the network time server.

Syntax

object.SetTime([*NetworkTime*])

Parameters

NetworkTime

An optional date value which specifies the new system time. If this is passed as a string, it will be parsed according to the local system settings; if the string is not in a recognizable format, the method will return an error. Note that the string must specify the full date and time, not simply a time value. If this argument is omitted, the date and time value last returned from a call to the **GetTime** method will be used. This enables an application to synchronize the local system time with the time returned by the server.

Return Value

A boolean value of true is returned if the operation was successful, otherwise the method will return false. Check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **SetTime** method causes the control to update the local system's clock to the specified date and time. It is required that the user have the appropriate privileges required to change the system clock, otherwise an error will be returned.

See Also

[LocalDate Property](#), [LocalTime Property](#), [SystemDate Property](#), [SystemTime Property](#), [GetTime Method](#)

Uninitialize Method

Uninitialize the control and release any system resources that were allocated.

Syntax

object.Uninitialize

Parameters

None.

Return Value

None.

Remarks

The **Uninitialize** method terminates any connection established by the control and resets the internal state of the control. This method is not typically used because any resources that have been allocated by an instance of the control will automatically be released when it is destroyed.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the control will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the control was created. An application should only call the **Uninitialize** method if it has explicitly called the **Initialize** method.

See Also

[Initialize Method](#)

Network Time Protocol Control Events

Event	Description
OnCancel	This event occurs when a blocking operation is canceled
OnError	This event occurs when a control error occurs
OnTimeout	This event occurs when a blocking operation times out
OnTimer	This event occurs when the control's preset timer interval expires

OnCancel Event

The **OnCancel** event is generated when a blocking operation is canceled.

Syntax

Sub *object_OnCancel* ([*Index As Integer*])

Remarks

This event occurs when a blocking operation on the socket, such as sending or receiving data, is canceled with the **Cancel** method. To assist in determining which operation was canceled, consult the **State** property.

See Also

[Cancel Method](#), [OnError Event](#), [OnTimeout Event](#)

OnError Event

The **OnError** event is generated when a control error occurs.

Syntax

```
Sub object_OnError ( [Index As Integer,] ByVal ErrorCode As Variant, ByVal Description As Variant )
```

Remarks

This event occurs when an error occurs during a control action. Errors not generated by the control itself, such as errors related to the programming language or general component errors, do not trigger this event.

The ***ErrorCode*** argument specifies the last error that has occurred. If the error is network related, the error code values returned by the control correspond to those returned by the standard Windows Sockets library.

The ***Description*** argument is a string that describes the error.

See Also

[LastError Property](#), [LastErrorString Property](#), [ThrowError Property](#)

OnTimeout Event

The **OnTimeout** event is fired when a blocking operation times out.

Syntax

Sub *object_OnTimeout* ([*Index As Integer*])

Remarks

The **OnTimeout** event is generated when a blocking socket operation, such as sending or receiving data, times out. To determine which operation was in progress when the timeout occurred, consult the **State** property.

See Also

[Timeout Property](#), [OnCancel Event](#)

OnTimer Event

The **OnTimer** event is fired when the control's preset timer interval expires.

Syntax

Sub *object_OnTimer* ([*Index As Integer*])

Remarks

The **OnTimer** is generated when the control's timer interval has elapsed. The frequency is specified in milliseconds by setting the **Interval** property.

Control Information

Object Name	WebLocationCtl.WebLocation
File Name	CSWIPX12.OCX
Version	12.0.3024.1286
ProgID	SocketTools.WebLocation.12
ClassID	A8E6A3FF-248A-420C-88A4-0453B1F270C1
Threading Model	Apartment
Help File	CST12CTL.CHM
Dependencies	None

Overview

The Web Location control returns information about the location associated with the with the external IP address of the local system. The accuracy of this information can vary depending on the location, with the most detailed information being available for North America. The country and time zone information for all locations is generally accurate. However, as the location information becomes more precise, details such as city names, postal codes and specific geographic locations (e.g.: longitude and latitude) may have reduced accuracy.

This location information should not be used by programs that require extremely accurate map coordinates, such as navigation applications. The location information in North America should be generally accurate within a 25 mile (40km) radius. However, given the nature of how IP address location works, there is no guarantee that location information for any specific IP address or network will be accurate.

Software that is designed to protect the privacy of users, such as those which route all Internet traffic through proxy servers or VPNs, can significantly impact the accuracy of this information. In this case, the data returned by this control may reflect the location of the network or proxy server, and not the location of the person using your application. It is recommended that you always request permission from the user before acquiring their location, have them confirm that the location is correct and provide a mechanism for them to update that information.

This control uses SocketTools services and will only function if there is an active Internet connection and the local system is capable of establishing a secure connection to the location service.

Requirements

The SocketTools ActiveX Edition components are self-registering controls that are compatible with any

programming language that supports the Component Object Model (COM) and the ActiveX control specification. If you are using Visual Basic 6.0, Service Pack 6 (SP6) is required. We recommend installing all available updates for your development tools. Although the Visual Basic 6.0 runtime is supported on Windows 11, the IDE itself is no longer officially supported by Microsoft. Legacy IDEs and compilers may also require elevated (administrator) privileges to run properly.

The ActiveX controls are supported on Windows 7, Windows Server 2008 R2, and later versions of both desktop and server editions of Windows. For Windows 7, Service Pack 1 (SP1) is the minimum requirement. For Windows 8 systems, the 8.1 update must be installed. On ARM-based platforms, the minimum supported version is Windows 10 build 1709.

SocketTools includes components for both 32-bit (x86) and 64-bit (x64) Windows platforms. All modern versions of Windows are 64-bit, but we continue to include 32-bit components for compatibility with legacy development tools such as Visual Basic 6.0. We also provide native ARM64 ActiveX controls for systems running Windows on ARM. Note that 32-bit applications on ARM run using x86 emulation, and Microsoft no longer supports native ARM32 applications.

If you are using VBScript, Visual Basic for Applications (VBA), or another scripting environment on an ARM-based system, be aware that 64-bit hosts will require ARM64 components, while 32-bit hosts will use x86 components under emulation. This includes applications created with Visual Basic 6.0. To reduce deployment complexity and avoid confusion, SocketTools does not include ARM32 ActiveX controls in its standard redistribution packages but they are available on request for legacy or specialized scenarios.

Distribution

When you distribute an application that uses this control, you can either install the file in the same folder as your application executable or as a shared component in the appropriate system folder. If you install the control in the system folder, it is important that you distribute the correct version for the target platform and it must be registered. If you install the control in the same folder as your executable, it is recommended that you use registration-free activation or COM redirection to ensure that the correct version of the control is loaded by the application.

Web Location Control Properties

Property	Description
ASNumber	Gets the autonomous system number for the network
CityName	Gets the city name for the current location
Coordinates	Gets the GPS coordinates for the current location
CountryAlpha	Gets the ISO alpha-2 code for the country at the current location
CountryCode	Gets the numeric code for the country at the current location
CountryName	Gets the name of the country for the current location
IPAddress	Gets the external IP address for the local system
IsInitialized	Determine if the control has been initialized
LastError	Gets and sets the last error that occurred on the control
LastErrorString	Returns a description of the last error to occur
LastUpdate	Gets the number of seconds since the last location update
Latitude	Gets the latitude for the current location
LocalTime	Gets the local time adjusted for the location's time zone
LocationId	Gets a unique identifier for the current location
Longitude	Gets the longitude for the current location
Organization	Gets the name of the organization that owns the network
PostalCode	Gets the postal code for the current location
RegionCode	Gets the numeric region code for the current location
RegionName	Gets the region name for the current location
Subdivision	Gets the subdivision name for the current location
SubdivisionCode	Gets the alphanumeric code for the current subdivision
ThrowError	Enables or disables error handling by the application
Timeout	Gets and sets the amount of time until a blocking operation fails
Timezone	Gets the time zone for the current location
Trace	Enable or disable socket function level tracing
TraceFile	Specify the socket function trace output file
TraceFlags	Gets and sets the socket function tracing flags
TzOffset	Gets the time zone offset in seconds for the current location
TzShortName	Gets an abbreviated time zone name for the current location
Version	Return the current version of the control

ASNumber Property

Gets the autonomous system number for the network.

Syntax

object.ASNumber

Remarks

This property returns an integer value which is used to uniquely identify a global network (autonomous system) that is connected to the Internet. This number is assigned by regional registries and used by large networks, such as Internet Service Providers, for exchanging routing information with one another. This value can be used to determine the ownership of a particular network.

Data Type

Integer (Int32)

See Also

[IPAddress Property](#), [LocationId Property](#), [Organization Property](#)

CityName Property

Gets the city name for the current location.

Syntax

object.CityName

Remarks

This property returns a string which identifies the city in which the external IP address is located. These names will always be in English, regardless of the current system locale. If the city name cannot be determined, this property may return an empty string.

Data Type

String

See Also

[CountryName Property](#), [PostalCode Property](#), [RegionName Property](#), [Subdivision Property](#)

Coordinates Property

Gets the GPS coordinates for the current location.

Syntax

object.Coordinates

Remarks

This property returns a string which specifies the location expressed using the Universal Transverse Mercator (UTM) coordinate system with the WGS-84 ellipsoid. UTM coordinates are commonly used with the Global Positioning System (GPS) and are comprised of three parts: the zone, the easting (the eastward-measured distance or *x*-coordinate) and the northing (the northward-measured distance or *y*-coordinate). An example of a string value returned by this property would be "14S 702089E 3646476N".

Data Type

String

See Also

[Latitude Property](#), [Longitude Property](#)

CountryAlpha Property

Gets the ISO alpha-2 code for the country at the current location.

Syntax

object.CountryAlpha

Remarks

This property returns a string which contains the ISO 3166-1 alpha-2 code for the country the external IP address is located in. This is a two-letter country code established by the International Organization for Standardization (ISO).

The **SubdivisionCode** property can be used to determine the standard ISO standard code for a regional subdivision (such as a state, province or territory). For example, if the IP address is located in Los Angeles, California the **CountryAlpha** property would return "US" and the **SubdivisionCode** property would return "CA".

Data Type

String

See Also

[CountryCode Property](#), [CountryName Property](#), [RegionName Property](#), [Subdivision Property](#), [SubdivisionCode Property](#)

CountryCode Property

Gets the numeric code for the country at the current location.

Syntax

object.CountryCode

Remarks

This property returns an integer value which identifies the country where the external IP address is located. These codes can be up to three digits (usually displayed with leading zeros as necessary) and correspond to the country codes assigned by the United Nations. For example, the code for the United States is 840. It is important to note that these are not international dialing codes and should not be used with telephony applications.

Data Type

Integer (Int32)

See Also

[CountryAlpha Property](#), [CountryName Property](#), [RegionName Property](#), [Subdivision Property](#)

CountryName Property

Gets the name of the country for the current location.

Syntax

object.CountryName

Remarks

This property returns a string which contains the full name of the country in which the external IP address is located. These names will always be in English, regardless of the current system locale.

Data Type

String

See Also

[CountryAlpha Property](#), [CountryCode Property](#), [RegionName Property](#), [Subdivision Property](#)

IPAddress Property

Gets the external IP address for the local system.

Syntax

object.IPAddress

Remarks

This property returns a string which specifies the external IP address for the local system. If the system has been assigned multiple IP addresses, it reflects the address of the interface that was used to establish a connection with the SocketTools server. If the connection is made through a Virtual Private Network (VPN) it will use that assigned IP address. If a connection is made through a proxy server, the IP address may be address of the proxy rather than the local host, depending on how the connection is made.

This property cannot be assigned a value to query the location of different IP addresses. If the external IP address of the local system cannot be determined, this property will return an empty string.

Data Type

String

See Also

[ASNumber Property](#), [LocationId Property](#), [Organization Property](#)

IsInitialized Property

Determine if the control has been initialized.

Syntax

object.IsInitialized

Remarks

The **IsInitialized** property is used to determine if the current instance of the control has been initialized properly. Normally this is done automatically when the control is loaded, however there are circumstances where the control may not be able to initialize itself. If this property returns **False**, the application must call the **Initialize** method to initialize the control before performing any other operation.

The most common reason that the control may not initialize correctly is that no valid development or runtime license key can be found or the license key that was provided is invalid. It may also indicate a problem with the system configuration or user access rights, such as not being able to load the required networking libraries or not being able to access the system registry.

Data Type

Boolean

See Also

[Initialize Method](#)

LastError Property

Gets and sets the last error that occurred on the control.

Syntax

object.LastError [= *value*]

Remarks

The **LastError** property can be read to determine the last error that occurred for this control. If a value is assigned to this property, it must either be zero to clear the error or a valid error code for the control.

Data Type

Integer (Int32)

See Also

[LastErrorString Property](#), [OnError Event](#)

LastErrorString Property

Return a description of the last error to occur.

Syntax

object.LastErrorString

Remarks

The **LastErrorString** property returns a description of the last error that occurred. This can be used to display a meaningful error message to a user, rather than just the numeric value returned by the **LastError** property.

Data Type

String

See Also

[LastError Property](#), [OnError Event](#)

Latitude Property

Gets the latitude for the current location.

Syntax

object.Latitude

Remarks

This property returns a value which specifies the latitude of the location in decimal format. A positive value indicates a location that is north of the equator, while a negative value is a location that is south of the equator.

Data Type

Double

See Also

[Coordinates Property](#), [Longitude Property](#)

LastUpdate Property

Gets the number of seconds since the last location update.

Syntax

object.LastUpdate

Remarks

This property returns an integer value which specifies the number of seconds since the last location query was performed by the control. A return value of zero indicates that the current location has not been updated.

Data Type

Integer (Int32)

See Also

[Reset Method](#), [Update Method](#)

LocalTime Property

Gets the local time adjusted for the location's time zone.

Syntax

object.LocalTime

Remarks

This property returns a string which contains the current date and time at the location, adjusted for its time zone and whether or not it's in daylight savings time. The format of the date and time is determined by the current locale and system configuration.

Data Type

String

See Also

[Timezone Property](#), [TzOffset Property](#), [TzShortName Property](#)

LocationId Property

Gets a unique identifier for the current location.

Syntax

object.LocationId

Remarks

This property returns a string of hexadecimal characters which uniquely identifies the location for this computer system. This value is used internally by the location service, and may also be used by the application for its own purposes. If this value changes in subsequent queries, it indicates the external IP address for the local system has changed.

Data Type

String

See Also

[ASNumber Property](#), [IPAddress Property](#), [Organization Property](#)

Longitude Property

Gets the longitude for the current location.

Syntax

object.Longitude

Remarks

This property returns a value which specifies the longitude of the location in decimal format. A positive value indicates a location that is east of the prime meridian, while a negative value is a location that is west of the prime meridian.

Data Type

Double

See Also

[Coordinates Property](#), [Latitude Property](#)

Organization Property

Gets the name of the organization that owns the network.

Syntax

object.Organization

Remarks

This property returns a string which identifies the organization associated with the local system's external IP address. For residential end-users this is typically the name of their Internet Service provider, however it may also identify a private company such as Microsoft, Google or Amazon. Because of the nature of how this information is updated, the organization names can change over time due to acquisitions or changes of ownership. If the owner of the network cannot be determined, this property may return an empty string.

Data Type

String

See Also

[ASNumber Property](#), [IPAddress Property](#), [LocationId Property](#)

PostalCode Property

Gets the postal code for the current location.

Syntax

object.PostalCode

Remarks

This property returns a string which contains the postal code associated with the area where the IP address is located. In the United States, this is a 5-digit numeric code. In Canada, this will contain the forward sortation area (the first three characters of the six character postal code). Local delivery portions of a postal code (such as the ZIP+4 code in the United States, or the local delivery unit in Canada) are not included.

This information will be most accurate within the geographic region of North America. Postal codes are locale specific, and this property may return an empty string if the postal code for the location cannot be determined.

Data Type

String

See Also

[CityName Property](#), [CountryName Property](#), [RegionName Property](#), [Subdivision Property](#)

RegionCode Property

Gets the numeric region code for the current location.

Syntax

object.RegionCode

Remarks

This property returns an integer value which identifies the geographical region in which the external IP address is located. This value corresponds to the name returned by the **RegionName** property. The numeric values use the UN M49 standard established by the United Nations Statistics Division.

Data Type

Integer (Int32)

See Also

[CityName Property](#), [CountryName Property](#), [RegionName Property](#), [Subdivision Property](#)

RegionName Property

Gets the region name for the current location.

Syntax

object.RegionName

Remarks

This property returns a string which identifies the region in which the external IP address is located. This refers to a broad geographical area, such as "North America" or "Southeast Asia" and uses the conventions for supranational regions as defined by UN M49 codes. These names will always be in English, regardless of the current system locale.

Data Type

String

See Also

[CityName Property](#), [CountryName Property](#), [RegionCode Property](#), [Subdivision Property](#)

Subdivision Property

Gets the subdivision name for the current location.

Syntax

object.Subdivision

Remarks

This property returns a string which identifies the geopolitical subdivision within a country where the external IP address is located. In the United States, this will contain the full name of the state or commonwealth. In Canada, this will contain the name of the province or territory. These names will always be in English, regardless of the current system locale.

If a subdivision name does not exist for the location, this property will return an empty string.

The **SubdivisionCode** property will return a standardized abbreviation for the area. For example, in the United States it would return the two-character code for the state.

Data Type

String

See Also

[CityName Property](#), [CountryName Property](#), [RegionName Property](#), [SubdivisionCode Property](#)

SubdivisionCode Property

Gets the alphanumeric code for the current subdivision.

Syntax

object.SubdivisionCode

Remarks

This property returns a string which is either a two- or three-letter code which identifies a geopolitical subdivision within the country where the external IP address is located. These codes are defined by the ISO 3166-2 standard. For example, the code for the state of California in the United States is "CA".

For international specificity, these subdivision codes are often combined with the value of the ISO alpha-2 code returned by the **CountryAlpha** property. For example, to identify the state of California, you could combine with the alpha-2 code for the United States, creating "US-CA" as an identifier.

If a subdivision code does not exist for the location, this property will return an empty string.

Data Type

String

See Also

[CountryAlpha Property](#), [CountryCode Property](#), [RegionCode Property](#), [Subdivision Property](#)

ThrowError Property

Enables or disables error handling by the application.

Syntax

object.**ThrowError** = { True | False }

Remarks

Error handling for methods can be performed using either return codes or exceptions, depending on the value of this property.

If the **ThrowError** property is set to False, methods will return a status value indicating success or failure. Applications should check the return value of each method and use the **LastError** and **LastErrorString** properties to determine the cause of any error.

If the **ThrowError** property is set to True, errors occurring within the control will be raised to the host application as ActiveX exceptions. In addition, the **OnError** event will fire. This allows applications to use language-specific exception handling mechanisms, such as Visual Basic error handling, instead of checking individual return values after each method call.

Even when the **ThrowError** property is set to True, the **LastError** and **LastErrorString** properties will still be updated with information about the most recent error.

If an error occurs while accessing a property value, an exception will be raised regardless of the value of the **ThrowError** property. However, the **OnError** event will not be fired for property access errors.

Data Type

Boolean

See Also

[LastError Property](#), [LastErrorString Property](#), [OnError Event](#)

Timeout Property

Gets and sets the number of seconds to wait until a location query fails.

Syntax

object.Timeout [= *seconds*]

Remarks

Setting this property specifies the number of seconds until a request for location information fails and returns an error. This includes the amount of time spent attempting to connect to the location service. If a connection cannot be established within the given time period, the operation will fail.

Data Type

Integer (Int32)

See Also

[Update Method](#)

Timezone Property

Gets the time zone for the current location.

Syntax

object.**Timezone**

Remarks

This property returns a string which specifies the full time zone name in which the external IP address is located. These names are defined by the Internet Assigned Numbers Authority (IANA) and have values like "America/Los_Angeles" and "Europe/London". These time zones may also be defined as "Etc/GMT+10" if there is not a regional name associated with the time zone.

The **TzShortName** property will return an abbreviated time zone name, such as "PST".

Data Type

String

See Also

[LocalTime Property](#), [TzOffset Property](#), [TzShortName Property](#)

Trace Property

Enable or disable network function level logging.

Syntax

`object.Trace` [= { True | False }]

Remarks

The **Trace** property is used to enable or disable the logging of network function calls. When enabled, each function call is logged to a file, including the function parameters, return value and error code if applicable. This facility can be enabled and disabled at run time, and the trace log file can be specified by setting the **TraceFile** property. All function calls that are being logged are appended to the trace file, if it exists. If no log file exists when tracing is enabled, the file is created.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

Data Type

Boolean

See Also

[TraceFile Property](#), [TraceFlags Property](#)

TraceFile Property

Gets and sets the name of the file to use when logging network function calls.

Syntax

`object.TraceFile [= filename ]`

Remarks

The **TraceFile** property is used to specify the name of the file that is created when logging is enabled. If this property is set to an empty string (the default value), then a file named **SocketTools.log** is created in the current user's Documents folder. It is recommended that you always specify a complete path to the log file. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

If the file exists, the output is appended to the file, otherwise the file is created. Since logging is enabled per-process, the log file is shared by all instances of the controls being used. If you create multiple instances of the control, you only need to enable logging for a single instance. Because log files can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "0x". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxx:xxxx:xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, the control is attempting to connect to a system with the IPv4 address 192.0.0.1 on port 1234.

If the log file cannot be created, or the user does not have permission to modify an existing file, the error is silently ignored and no output will be generated.

Data Type

String

See Also

TraceFlags Property

Gets and sets the network function logging flags.

Syntax

object.TraceFlags [= *flags*]

Remarks

The **TraceFlags** property is used to specify the type of information written to the trace file when socket function tracing is enabled. The following values may be used:

Value	Description
dnsTraceInfo	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
dnsTraceError	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
dnsTraceWarning	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
dnsTraceHexDump	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
dnsTraceTruncate	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.

Since logging is enabled per-process, the trace flags are shared by all instances of the control being used. If multiple controls have tracing enabled, the **TraceFlags** property should be set to the same value for each control. Changing the trace flags for any one instance of the control will affect the logging performed for all other instances used by the application.

Warnings are generated when a non-fatal error is returned by a Windows Sockets function. For example, if data is being written through the control and an error indicating that the operation would block is returned, only a warning is logged since the application simply needs to attempt to write the data at a later time.

Data Type

Integer (Int32)

See Also

[Trace Property](#), [TraceFile Property](#)

TzOffset Property

Gets the time zone offset in seconds for the current location.

Syntax

object.TzOffset

Remarks

This property returns an integer which specifies the number of seconds east or west of the prime meridian (UTC). A positive value indicates a time zone that is east of the prime meridian and a negative value indicates a time zone that is west of the prime meridian. For example, the Pacific time zone in the western United States during daylight savings time would have a value of -25200 (7 hours).

Data Type

Integer (Int32)

See Also

[LocalTime Property](#), [Timezone Property](#), [TzShortName Property](#)

TzShortName Property

Gets an abbreviated time zone name for the current location.

Syntax

object.TzShortName

Remarks

This property returns a string which specifies the abbreviated time zone code in which the external IP address is located. If daylight savings time is used within the time zone, then this value can change based on whether or not daylight savings is in effect. For example, if the IP address is located within the Pacific time zone in the United States, this will return "PDT" when daylight savings is in effect and "PST" when it is not.

If the time zone code cannot be determined for this location, a value such as "UTC+9" may be returned, indicating the number of hours ahead or behind UTC.

Data Type

String

See Also

[LocalTime Property](#), [Timezone Property](#), [TzOffset Property](#)

Version Property

Return the current version of the control.

Syntax

object.Version

Remarks

The **Version** property returns the current version of the object. This can be used by an application for validation purposes. The version returned is composed of four numbers, separated by periods. The first number is the major version number, the second number is the minor version number, the third is the build number and the fourth is the revision number.

Data Type

String

Web Location Control Methods

Method	Description
Initialize	Initialize the control and validate the runtime license key
Reset	Reset the internal state of the control
Uninitialize	Uninitialize the control and release any system resources that were allocated
Update	Update the current location information for the local system

Initialize Method

Initialize the control and validate the runtime license key.

Syntax

```
object.Initialize( [LicenseKey] )
```

Parameters

LicenseKey

An optional string value which specifies a runtime license key used to initialize the control. If the license key is omitted or passed as an empty string, a development license must be installed on the local system.

Return Value

A value of zero is returned if the control was initialized successfully. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

This method dynamically loads other system libraries and allocates thread local storage. In most cases, it is not necessary to call this method directly because it is automatically invoked when an instance of the control is created by the container. However, if the control is created dynamically using **CreateObject** or a similar method, this must be the first method that is called before you attempt to modify any property values or invoke other methods. Failure to initialize the control may result in subsequent errors and/or cause an exception to be raised.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the control will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the control was created.

If the control is being used within another DLL, it is important that you do not attempt to create an instance of the control or call the **Initialize** method from within the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is written in C++ and it is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for any static and global C++ objects and has the same restrictions.

Example

```
Set ipLocation = CreateObject("SocketTools.WebLocation.12")

nError = ipLocation.Initialize(strLicenseKey)
If nError > 0 Then
    MsgBox "Unable to initialize SocketTools component"
End
End If
```

See Also

[IsInitialized Property](#), [Uninitialize Method](#)

Reset Method

Reset the internal state of the control.

Syntax

object.Reset

Parameters

None.

Return Value

None.

Remarks

The **Reset** method resets the internal state of the control. Property values are initialized to their internal defaults, open network connections will be closed and any resources allocated by the control will be released.

See Also

[Initialize Method](#), [Uninitialize Method](#)

Uninitialize Method

Uninitialize the control and release any system resources that were allocated.

Syntax

object.Uninitialize

Parameters

None.

Return Value

None.

Remarks

The **Uninitialize** method resets the internal state of the control and releases system resources allocated for this class instance. This method is not typically used because any resources that have been allocated by an instance of the control will automatically be released when it is destroyed.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the control will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the control was created. An application should only call the **Uninitialize** method if it has explicitly called the **Initialize** method.

See Also

[Initialize Method](#)

Update Method

Update the current location information for the local system.

Syntax

object.Update

Parameters

None.

Return Value

A value of True is returned if the current location was updated successfully. A value of False indicates that the current location could not be determined. The **LastError** property can be used to identify the specific cause of the failure.

Remarks

This method causes the control to query the location service to obtain current information about the physical location of the computer system based on its external IP address. The location data is cached and additional queries are only performed if it detects the external IP address for the local system has changed.

See Also

[LastUpdate Property](#), [Timeout Property](#)

Web Location Control Events

Event	Description
OnError	This event occurs when a control error occurs

OnError Event

The **OnError** event is generated when a control error occurs.

Syntax

```
Sub object_OnError ( [Index As Integer,] ByVal ErrorCode As Variant, ByVal Description As Variant )
```

Remarks

This event occurs when an error occurs during a control action. Errors not generated by the control itself, such as errors related to the programming language or general component errors, do not trigger this event.

The ***ErrorCode*** argument specifies the last error that has occurred. If the error is network related, the error code values returned by the control correspond to those returned by the standard Windows Sockets library.

The ***Description*** argument is a string that describes the error.

Control Information

Object Name	WebStorageCtl.WebStorage
File Name	CSWEBX12.OCX
Version	12.0.3024.1286
ProgID	SocketTools.WebStorage.12
ClassID	4B0A4542-02B2-42ED-9816-E001B1A4C4D4
Threading Model	Apartment
Help File	CST12CTL.CHM
Dependencies	None

Overview

The Web Storage control enables an application to securely store and manage data remotely.

This control uses SocketTools Web Services and will only function if there is an active Internet connection and the local system is capable of establishing a secure connection to our servers.

Requirements

The SocketTools ActiveX Edition components are self-registering controls that are compatible with any programming language that supports the Component Object Model (COM) and the ActiveX control specification. If you are using Visual Basic 6.0, Service Pack 6 (SP6) is required. We recommend installing all available updates for your development tools. Although the Visual Basic 6.0 runtime is supported on Windows 11, the IDE itself is no longer officially supported by Microsoft. Legacy IDEs and compilers may also require elevated (administrator) privileges to run properly.

The ActiveX controls are supported on Windows 7, Windows Server 2008 R2, and later versions of both desktop and server editions of Windows. For Windows 7, Service Pack 1 (SP1) is the minimum requirement. For Windows 8 systems, the 8.1 update must be installed. On ARM-based platforms, the minimum supported version is Windows 10 build 1709.

SocketTools includes components for both 32-bit (x86) and 64-bit (x64) Windows platforms. All modern versions of Windows are 64-bit, but we continue to include 32-bit components for compatibility with legacy development tools such as Visual Basic 6.0. We also provide native ARM64 ActiveX controls for systems running Windows on ARM. Note that 32-bit applications on ARM run using x86 emulation, and Microsoft no longer supports native ARM32 applications.

If you are using VBScript, Visual Basic for Applications (VBA), or another scripting environment on an

ARM-based system, be aware that 64-bit hosts will require ARM64 components, while 32-bit hosts will use x86 components under emulation. This includes applications created with Visual Basic 6.0. To reduce deployment complexity and avoid confusion, SocketTools does not include ARM32 ActiveX controls in its standard redistribution packages but they are available on request for legacy or specialized scenarios.

Distribution

When you distribute an application that uses this control, you can either install the file in the same folder as your application executable or as a shared component in the appropriate system folder. If you install the control in the system folder, it is important that you distribute the correct version for the target platform and it must be registered. If you install the control in the same folder as your executable, it is recommended that you use registration-free activation or COM redirection to ensure that the correct version of the control is loaded by the application.

Web Storage Control Properties

Property	Description
AccountId	Gets a value that specifies the storage account ID
AppId	Gets the application identifier associated with the storage container
IsBlocked	Determine if a blocking storage operation is in progress
IsConnected	Determine if the application is connected to the storage server
IsInitialized	Determine if the control has been initialized
LastError	Gets and sets the last error that occurred on the control
LastErrorString	Returns a description of the last error to occur
ObjectAttributes	Gets the attributes for the current object
ObjectContent	Gets the content type for the current object
ObjectCreated	Gets the date and time the current object was created
ObjectDigest	Gets the SHA-256 digest value for the current object
ObjectId	Gets the unique identifier for the current object
ObjectLabel	Gets the label for the current object
ObjectLimit	Gets the maximum number of objects that may be created
ObjectModified	Gets the date and time the current object was last modified
ObjectSize	Gets the size of the current object in bytes
StorageFree	Gets the total number of bytes available to store new objects
StorageId	Gets a unique identifier for the current storage container
StorageLimit	Gets the maximum number of bytes of storage available
StorageObjects	Gets the current number of objects stored for your account
StorageType	Gets the current storage container type identifier
StorageUsed	Gets the current number of bytes of storage used for your account
ThrowError	Enables or disables error handling by the application
Timeout	Gets and sets the amount of time until a blocking operation fails
Trace	Enable or disable socket function level tracing
TraceFile	Specify the socket function trace output file
TraceFlags	Gets and sets the socket function tracing flags
TransferBytes	Gets the number of bytes transferred from the storage server
TransferRate	Gets the current data transfer rate in bytes per second
TransferTime	Gets the number of seconds elapsed for the current data transfer
Version	Return the current version of the control

AccountId Property

Gets a value that specifies the storage account ID associated with the development license.

Syntax

object.AccountId

Remarks

This property is a string that uniquely identifies the web services account that is associated with the session. The account ID corresponds with your product serial number and runtime license key, but it is not identical to either of those values.

If you are using an evaluation license, the account ID is temporary and only valid during the evaluation period. After the evaluation period has expired, the account ID is revoked and objects stored using this ID will be deleted. It is not recommended that you store critical application data using an evaluation license.

Data Type

String

See Also

[AppId Property](#), [ObjectId Property](#), [StorageId Property](#)

AppId Property

Gets the application identifier associated with the storage container.

Syntax

object.AppId

Remarks

This property returns the current application ID. The application ID is a string that uniquely identifies the application and can only contain letters, numbers, the period and the underscore character. The default value for this property is **SocketTools.Storage.Default**.

You can register a unique identifier for your application using the **RegisterId** method.

Data Type

String

See Also

[ObjectId Property](#), [RegisterId Method](#), [ValidateId Method](#), [UnregisterId Method](#)

IsBlocked Property

Determine if a blocking storage operation is in progress.

Syntax

object.IsBlocked

Remarks

The **IsBlocked** property is used to determine if a storage operation is currently in progress. For example, this property will return True if checked within an **OnProgress** event handler when the **GetFile** or **PutFile** method has been called.

Data Type

Boolean

See Also

[GetData Method](#), [GetFile Method](#), [PutData Method](#), [PutFile Method](#), [OnProgress Event](#)

IsConnected Property

Determine if the application is connected to the storage server.

Syntax

object.IsConnected

Remarks

The **IsConnected** property is used to determine if the application is connected to the storage server. This property will return **False** if the **Open** method has not been called to open a storage container, or if the connection to the server has been terminated. A value of **True** indicates that the storage container has been opened and there is a valid connection to the server.

The client does not maintain a continuous, persistent connection with the storage server. The connection may be closed and reopened internally as needed. If the client session has been idle for a period of time, this property can return **False**. If the **LastError** property returns **stErrorNotConnected** it means the client session is valid, however it not currently connected to the storage server. The next call to store or retrieve an object will the cause the client to reconnect automatically.

Data Type

Boolean

See Also

[LastError Property](#), [Close Method](#), [Open Method](#)

IsInitialized Property

Determine if the control has been initialized.

Syntax

object.IsInitialized

Remarks

The **IsInitialized** property is used to determine if the current instance of the control has been initialized properly. Normally this is done automatically when the control is loaded, however there are circumstances where the control may not be able to initialize itself. If this property returns **False**, the application must call the **Initialize** method to initialize the control before performing any other operation.

The most common reason that the control may not initialize correctly is that no valid development or runtime license key can be found or the license key that was provided is invalid. It may also indicate a problem with the system configuration or user access rights, such as not being able to load the required networking libraries or not being able to access the system registry.

Data Type

Boolean

See Also

[Initialize Method](#)

LastError Property

Gets and sets the last error that occurred on the control.

Syntax

object.LastError [= *value*]

Remarks

The **LastError** property can be read to determine the last error that occurred for this control. If a value is assigned to this property, it must either be zero to clear the error or a valid error code for the control.

Data Type

Integer (Int32)

See Also

[LastErrorString Property](#), [OnError Event](#)

LastErrorString Property

Return a description of the last error to occur.

Syntax

object.LastErrorString

Remarks

The **LastErrorString** property returns a description of the last error that occurred. This can be used to display a meaningful error message to a user, rather than just the numeric value returned by the **LastError** property.

Data Type

String

See Also

[LastError Property](#), [OnError Event](#)

ObjectAttributes Property

Gets the attributes for the current object.

Syntax

object.ObjectAttributes

Remarks

This property returns an integer value that specifies the attributes for the current storage object. The object attributes are comprised of one or more bit flags.

Value	Description
webObjectDefault	Default object attributes. This value is used to indicate the object can be modified, or that the attributes for a previously existing object should not be changed.
webObjectNormal	A normal object that that can be read and modified by the application. This is the default attribute for new objects that are created by the application.
webObjectReadOnly	A read-only object that can only be read by the application. Attempts to modify or replace the contents of the object will fail. Read-only objects can be deleted.
webObjectHidden	A hidden object. Objects with this attribute are not returned when enumerated using the FindFirst and FindNext methods. The object can only be accessed directly when specifying its label.

Data Type

Integer (Int32)

See Also

[Exists Method](#), [FindFirst Method](#), [FindNext Method](#)

ObjectContent Property

Gets the content type for the current object.

Syntax

object.ObjectContent

Remarks

This property returns a string which specifies the MIME content type for the current storage object. The content type is typically determined by the object label and evaluating the contents of the object. It is also possible for the application to explicitly specify the content type of the object when it is created.

The object content type will always be in the format **type/subtype** where the type specifies a common media type (e.g.: text, audio, video, etc.) and subtype specifies the specific content. The most common content type for text files is **text/plain**. If the content type is unknown, the default content type is **application/octet-stream**.

Text objects may also optionally include the character encoding as part of the content type. For example, if an object contains UTF-8 encoded text, the content type may be returned as **text/plain; charset=utf-8**. If your application is parsing the content types, you must check if a character encoding was also included in the value. Text objects that do not specify an encoding either contain ASCII or text which uses the system code page. Unicode text will always be stored using UTF-8 encoding.

Data Type

String

See Also

[Exists Method](#), [PutData Method](#), [PutFile Method](#)

ObjectCreated Property

Gets the date and time the current object was created.

Syntax

object.ObjectCreated

Remarks

This property returns a string which specifies the date and time the current object was created. The format of the date and time string is determined by the system configuration and current locale.

Data Type

String

See Also

[ObjectModified Property](#), [Exists Method](#), [GetData Method](#), [GetFile Method](#)

ObjectDigest Property

Gets the SHA-256 digest value for the current object.

Syntax

object.ObjectDigest

Remarks

This property returns a string value which specifies the digest of the object contents, computed using an SHA-256 hash. The digest value is always represented as a string of hexadecimal numbers that is exactly 64 characters long. It is important to note that even a zero-length object will have a digest, which is the standard SHA-256 NULL hash value.

Data Type

String

See Also

[ObjectId Property](#), [ObjectContent Property](#), [ObjectSize Property](#), [Exists Method](#)

ObjectId Property

Gets the unique identifier for the current object.

Syntax

object.ObjectId

Remarks

This property returns a unique identifier associated with the current object. Object IDs are guaranteed to be unique for each storage object that is created by the application.

Data Type

String

See Also

[ObjectContent Property](#), [ObjectDigest Property](#), [ObjectLabel Property](#), [Exists Method](#)

ObjectLabel Property

Gets the label for the current object.

Syntax

object.ObjectLabel

Remarks

This property returns a string which specifies the label assigned to the current object by the application. Object labels are case-sensitive and must be unique for each object. An application uses labels to reference an object with a human-recognizable name, rather than referencing them by their object ID.

Object labels are similar to Windows file names, except they are case-sensitive. The maximum length of a label string is 511 characters. Leading and trailing whitespace (spaces, tabs, linebreaks, etc.) are ignored in label names.

Illegal characters include ASCII and Unicode control characters 0 through 31, single quotes (39), double quotes (34), less than symbol (60), greater than symbol (62), pipe (124), asterisk (42) and question mark (63). It is not possible to embed null characters in the label name.

Label names may contain forward slash (47) characters and backslash (92) characters, however it is important to note that objects are not stored in a hierarchical structure. An application can create its own folder-like structure to the labels it creates, but this structure is not imposed or enforced by the control.

Labels can contain Unicode characters which are internally encoded as UTF-8.

Data Type

String

See Also

[ObjectContent Property](#), [ObjectDigest Property](#), [ObjectId Property](#), [Exists Method](#), [ValidateLabel Method](#)

ObjectLimit Property

Gets the maximum number of objects that may be created.

Syntax

object.ObjectLimit

Remarks

This property returns an integer value which specifies the maximum number of storage objects that may be created. In addition to the limit on the total amount of storage that may be used, there is a limit on the total number of objects that may be created by all applications.

Data Type

Integer (Int32)

See Also

[StorageFree Property](#), [StorageLimit Property](#), [StorageObjects Property](#) [StorageUsed Property](#)

ObjectModified Property

Gets the date and time the current object was last modified.

Syntax

object.ObjectModified

Remarks

This property returns a string which specifies the date and time the current object was last modified. The format of the date and time string is determined by the system configuration and current locale.

Data Type

String

See Also

[ObjectCreated Property](#), [Exists Method](#), [GetData Method](#), [GetFile Method](#)

ObjectSize Property

Gets the size of the current object in bytes.

Syntax

object.ObjectSize

Remarks

This property returns a value that specifies the size of the current storage object in bytes.

Data Type

Integer (Int32)

See Also

[ObjectLimit Property](#) [StorageFree Property](#), [StorageLimit Property](#), [StorageUsed Property](#)

StorageFree Property

Gets the total number of bytes available to store new objects.

Syntax

object.StorageFree

Remarks

This property returns a value which specifies the number of bytes available for the storage of new objects. This value reflects the total amount of available storage across all applications registered with the development account. If this value is zero, your storage account has reached its storage limit.

If your storage quota has been exceeded, either because the total number of objects or the total bytes of storage has reached their limit, your applications will be unable to create new objects. Your application can continue to access existing objects, regardless of your current quota limits.

To free storage space, use the **Delete** method to delete individual storage objects that are no longer needed by your application, or use the **DeleteAll** method to delete all objects in the current container.

Data Type

Double

See Also

[ObjectLimit Property](#), [StorageLimit Property](#), [StorageObjects Property](#), [StorageUsed Property](#)

StorageId Property

Gets a unique identifier for the current storage container.

Syntax

object.StorageId

Remarks

This property returns a string which identifies the current storage container opened with the **Open** method. The storage ID is associated with your development license and is guaranteed to be a unique value. If no storage container has been opened, this property will return a zero-length string.

Data Type

String

See Also

[AppId Property](#), [ObjectId Property](#), [Open Method](#)

StorageLimit Property

Gets the maximum number of bytes of storage available.

Syntax

object.StorageLimit

Remarks

This property returns a value which specifies the maximum number of bytes of data storage available. This limit applies to all applications registered with the development account. In addition to limits on the total number of bytes that can be stored, there are also limits on the total number objects which may be created, and the individual size of each object.

Storage quota limits are assigned for each SocketTools development account. Accounts that are created with an evaluation license have much lower quota limits than a standard account and should be used for testing purposes only. After the evaluation period has ended, all objects stored using the evaluation license will be deleted.

This value does not represent limits on the storage used by a specific application. Quotas limits apply to all applications that are registered with the development account, which is identified with the runtime license key passed to the **Initialize** method.

If your storage quota has been exceeded, either because the total number of objects or the total bytes of storage has reached their limit, your applications will be unable to create new objects. Your application can continue to access existing objects, regardless of your current quota limits.

To free storage space, use the **Delete** method to delete individual storage objects that are no longer needed by your application, or use the **DeleteAll** method to delete all objects in the current container.

Data Type

Double

See Also

[ObjectLimit Property](#), [StorageLimit Property](#), [StorageObjects Property](#), [StorageUsed Property](#)

StorageObjects Property

Gets the current number of objects stored for your account.

Syntax

object.StorageObjects

Remarks

This property returns an integer value which specifies the number of storage objects allocated for the account. This value may not exceed the total number of objects specified by the **ObjectLimit** property.

Data Type

Integer (Int32)

See Also

[ObjectLimit Property](#), [StorageLimit Property](#), [StorageUsed Property](#)

StorageType Property

Gets the current storage container type identifier.

Syntax

object.StorageType

Remarks

This property returns an integer value which identifies the current storage container type. It may be one of the following values. If no storage container is currently open, this property will return a value of zero.

Value	Description
webStorageGlobal	Global storage. Objects stored using this storage type are available to all users. Any changes made to objects using this storage type will affect all users of the application. Unless there is a specific need to limit access to the objects stored by the application to specific domains, local machines or users, it is recommended that you use this storage type when creating new objects.
webStorageDomain	Local domain storage. Objects stored using this storage type are only available to users in the same local domain, as defined by the domain name or workgroup name assigned to the local system. If the domain or workgroup name changes, objects previously stored using this storage type will not be available to the application.
webStorageMachine	Local machine storage. Objects stored using this storage type are only available to users on the same local machine. The local machine is identified by unique characteristics of the system, including the boot volume GUID. Objects previously stored using this storage type will not be available on that system if the boot disk is reformatted.
webStorageUser	Current user storage. Objects stored using this storage type are only available to the current user logged in on the local machine. The user identifier is based on the Windows user SID that is assigned when the user account is created. If the user account is deleted, the objects previously stored using this storage type will not be available to the application.

The storage type specifies the type of container that objects will be stored in. You can think of the storage containers as special folders which store individual objects. In most cases, we recommend using **webStorageGlobal** which means that stored objects will be accessible to all users of your application. However, you can limit access to the stored objects based on the local domain, local machine ID or the current user SID.

If you specify anything other than global storage, objects can be orphaned if the system configuration changes. For example, if **webStorageMachine** is specified, the objects that are stored there can only be accessed from that computer system. If the system is reconfigured (for example, the boot volume formatted and Windows is reinstalled) the unique identifier for that system will change and the previous objects that were stored by your application can no longer be accessed.

It is advisable is to store critical application data and configuration information using **webStorageGlobal** and use other non-global storage containers for configuration information that is unique to that system and/or user which is not critical and can be easily recreated.

Data Type

Integer

See Also

[StorageId Property](#), [Open Method](#)

StorageUsed Property

Gets the current number of bytes of storage used for your account.

Syntax

object.StorageUsed

Remarks

This property returns a value which specifies the total number of bytes of data allocated for all storage objects. This value may not exceed the total number of bytes of storage available, which is returned by the **StorageLimit** property.

This value does not represent the storage used by a specific application. This property returns the amount of storage used by all applications that are registered with the development account, which is identified with the runtime license key passed to the **Initialize** method.

Data Type

String

See Also

[ObjectLimit Property](#), [StorageFree Property](#), [StorageLimit Property](#), [StorageObjects Property](#)

ThrowError Property

Enables or disables error handling by the application.

Syntax

object.**ThrowError** = { True | False }

Remarks

Error handling for methods can be performed using either return codes or exceptions, depending on the value of this property.

If the **ThrowError** property is set to False, methods will return a status value indicating success or failure. Applications should check the return value of each method and use the **LastError** and **LastErrorString** properties to determine the cause of any error.

If the **ThrowError** property is set to True, errors occurring within the control will be raised to the host application as ActiveX exceptions. In addition, the **OnError** event will fire. This allows applications to use language-specific exception handling mechanisms, such as Visual Basic error handling, instead of checking individual return values after each method call.

Even when the **ThrowError** property is set to True, the **LastError** and **LastErrorString** properties will still be updated with information about the most recent error.

If an error occurs while accessing a property value, an exception will be raised regardless of the value of the **ThrowError** property. However, the **OnError** event will not be fired for property access errors.

Data Type

Boolean

See Also

[LastError Property](#), [LastErrorString Property](#), [OnError Event](#)

Timeout Property

Gets and sets the amount of time until a blocking operation fails.

Syntax

object.Timeout [= *seconds*]

Remarks

Setting the **Timeout** property specifies the number of seconds until a blocking operation fails and the control returns an error.

Note that the **Timeout** property also determines the amount of time the control will spend attempting to connect to a server. If a connection is not established within the given time period, the connection attempt will fail.

Data Type

Integer (Int32)

Trace Property

Enable or disable network function level logging.

Syntax

`object.Trace [= { True | False } ]`

Remarks

The **Trace** property is used to enable or disable the logging of network function calls. When enabled, each function call is logged to a file, including the function parameters, return value and error code if applicable. This facility can be enabled and disabled at run time, and the trace log file can be specified by setting the **TraceFile** property. All function calls that are being logged are appended to the trace file, if it exists. If no log file exists when tracing is enabled, the file is created.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

Data Type

Boolean

See Also

[TraceFile Property](#), [TraceFlags Property](#)

TraceFile Property

Gets and sets the name of the file to use when logging network function calls.

Syntax

`object.TraceFile [= filename ]`

Remarks

The **TraceFile** property is used to specify the name of the file that is created when logging is enabled. If this property is set to an empty string (the default value), then a file named **SocketTools.log** is created in the current user's Documents folder. It is recommended that you always specify a complete path to the log file. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

If the file exists, the output is appended to the file, otherwise the file is created. Since logging is enabled per-process, the log file is shared by all instances of the controls being used. If you create multiple instances of the control, you only need to enable logging for a single instance. Because log files can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "0x". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxx:xxxx:xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, the control is attempting to connect to a system with the IPv4 address 192.0.0.1 on port 1234.

If the log file cannot be created, or the user does not have permission to modify an existing file, the error is silently ignored and no output will be generated.

Data Type

String

See Also

TransferBytes Property

Gets the number of bytes transferred from the storage server.

Syntax

object.TransferBytes

Remarks

The **TransferBytes** property returns the number of bytes that have been copied to or from the storage server. If this property is read while a transfer is ongoing, the property returns the number of bytes that have been copied up to that point. If read after a transfer has completed, the total number of bytes copied is returned.

This property value is reset with every data transfer.

Data Type

Integer (Int32)

See Also

[TransferRate Property](#), [TransferTime Property](#), [OnProgress Event](#)

TransferRate Property

Gets the current data transfer rate in bytes per second.

Syntax

object.TransferRate

Remarks

The **TransferRate** property returns the rate at which the file data is being transferred, expressed in bytes per second. If this property is read while a transfer is ongoing, it returns the current average transfer rate.

If this property is read after the transfer has completed, it returns the final transfer rate which is calculated as the total number of bytes transferred divided by the number of seconds to complete the transfer. This property value is reset with every data transfer.

Data Type

Integer (Int32)

See Also

[TransferBytes Property](#), [TransferTime Property](#), [OnProgress Event](#)

TransferTime Property

Gets the number of seconds elapsed for the current data transfer.

Syntax

object.TransferTime

Remarks

The **TransferTime** property returns the number of seconds that have elapsed since the data transfer started. If the property is read after the transfer has completed, it returns the total number of seconds it took to transfer the object data.

This property value is reset with every data transfer.

Data Type

Integer (Int32)

See Also

[TransferBytes Property](#), [TransferRate Property](#), [OnProgress Event](#)

TraceFlags Property

Gets and sets the network function logging flags.

Syntax

`object.TraceFlags [= flags ]`

Remarks

The **TraceFlags** property is used to specify the type of information written to the trace file when socket function tracing is enabled. The following values may be used:

Value	Description
dnsTraceInfo	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
dnsTraceError	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
dnsTraceWarning	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
dnsTraceHexDump	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
dnsTraceTruncate	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.

Since logging is enabled per-process, the trace flags are shared by all instances of the control being used. If multiple controls have tracing enabled, the **TraceFlags** property should be set to the same value for each control. Changing the trace flags for any one instance of the control will affect the logging performed for all other instances used by the application.

Warnings are generated when a non-fatal error is returned by a Windows Sockets function. For example, if data is being written through the control and an error indicating that the operation would block is returned, only a warning is logged since the application simply needs to attempt to write the data at a later time.

Data Type

Integer (Int32)

See Also

[Trace Property](#), [TraceFile Property](#)

Version Property

Return the current version of the control.

Syntax

object.Version

Remarks

The **Version** property returns the current version of the object. This can be used by an application for validation purposes. The version returned is composed of four numbers, separated by periods. The first number is the major version number, the second number is the minor version number, the third is the build number and the fourth is the revision number.

Data Type

String

Web Storage Control Methods

Method	Description
Cancel	Cancel the current storage operation
Close	Close the open storage container
CompareData	Compare the data in a buffer with a stored object
CompareFile	Compare the data in a file with a stored object
Copy	Copy the contents of a stored object to another container
Delete	Delete a stored object from the container
DeleteAll	Delete all stored objects from the current container
Exists	Determine if a specific stored object exists in the container
FindFirst	Find the first stored object that matches a label or content type
FindNext	Find the next stored object that matches a label or content type
GetData	Download the data in a stored object to a string or byte array buffer
GetFile	Download a stored object to a file on the local system
Initialize	Initialize the control and validate the runtime license key
Move	Move a stored object to another container
Open	Open a storage container
PutData	Upload the data in a string or byte array buffer to the storage container
PutFile	Upload a local file to the storage container
RegisterId	Register a new application identifier with the storage service
Rename	Change the label of an existing storage object
Reset	Reset the internal state of the control
Uninitialize	Uninitialize the control and release any system resources that were allocated
UnregisterId	Unregister a previously registered application identifier
ValidateId	Check an application identifier to ensure it is valid and exists
ValidateLabel	Validate an object label to ensure it uses allowed characters

Cancel Method

Cancels the current storage operation.

Syntax

object.Cancel

Parameters

None.

Return Value

None.

Remarks

The **Cancel** method cancels the current storage operation in the current thread. This is typically used inside an **OnProgress** event handler, causing the blocking method to return to the caller with an error indicating that the current operation was canceled. If a storage operation is not currently in progress, calling this method will have no effect.

See Also

[GetData Method](#), [GetFile Method](#), [PutData Method](#), [PutFile Method](#), [Reset Method](#), [OnProgress Event](#)

Close Method

Close the storage container.

Syntax

object.Close

Parameters

None.

Return Value

A value of True is returned if the storage container was opened. Otherwise, a value of False is returned and the **LastError** property will return the specific cause of the failure.

Remarks

The **Close** method should be called after all operations using the storage container have completed. The access token granted to the application will be released and the memory allocated for the session cache will be freed.

See Also

[Open Method](#), [Reset Method](#)

CompareData Method

Compare the data in a buffer with a stored object.

Syntax

object.CompareData(ObjectLabel, Buffer)

Parameters

ObjectLabel

A string which specifies the label of the object that should be compared against the contents of the buffer.

Buffer

A string or byte array which contains the data that should be compared against the contents of the object. If the buffer contains binary data (particularly data that contains embedded null bytes) this parameter must be a byte array. String values should only be used for text comparisons.

Return Value

A value of True is returned if the contents of the buffer matches the contents of the specified object. Otherwise, a value of False is returned and the **LastError** property will return the specific cause of the failure.

Remarks

The **CompareData** method performs a binary comparison of the data in the specified buffer with the contents of the storage object on the server. The amount of data in the buffer must match the size of the stored object exactly, or this method will fail. Partial comparisons are not supported by this method.

If you need to compare the contents of a file with a stored object, use the **CompareFile** method.

See Also

[CompareFile Method](#), [GetData Method](#), [PutData Method](#)

CompareFile Method

Compare the data in a file with a stored object.

Syntax

object.CompareFile(ObjectLabel, LocalFile)

Parameters

ObjectLabel

A string which specifies the label of the object that should be compared against the contents of the buffer.

LocalFile

A string which specifies the name of the file to compare against the contents of the stored object. If no path is specified in the file name, the current working directory will be used.

Return Value

A value of True is returned if the contents of the file matches the contents of the specified object. Otherwise, a value of False is returned and the **LastError** property will return the specific cause of the failure.

Remarks

The **CompareFile** method performs a binary comparison of the data in the file with the contents of the storage object on the server. The contents of the file must be identical to the contents of the stored object or the method will fail.

If you need to compare the contents of a file with a string or byte array, use the **CompareData** method.

See Also

[CompareData Method](#), [GetData Method](#), [PutData Method](#)

Copy Method

Copy the contents of a stored object to another container.

Syntax

```
object.Copy( OldLabel, NewLabel [, StorageType] )
```

Parameters

OldLabel

A string which specifies the label of the object that should be copied.

NewLabel

A string which specifies the new label for the copied object.

StorageType

A numeric value that identifies the storage container type. One of the following values should be specified. If this parameter is omitted, the object will be copied within the current container.

Value	Description
webStorageGlobal	Global storage. Objects stored using this storage type are available to all users. Any changes made to objects using this storage type will affect all users of the application. Unless there is a specific need to limit access to the objects stored by the application to specific domains, local machines or users, it is recommended that you use this storage type when creating new objects.
webStorageDomain	Local domain storage. Objects stored using this storage type are only available to users in the same local domain, as defined by the domain name or workgroup name assigned to the local system. If the domain or workgroup name changes, objects previously stored using this storage type will not be available to the application.
webStorageMachine	Local machine storage. Objects stored using this storage type are only available to users on the same local machine. The local machine is identified by unique characteristics of the system, including the boot volume GUID. Objects previously stored using this storage type will not be available on that system if the boot disk is reformatted.
webStorageUser	Current user storage. Objects stored using this storage type are only available to the current user logged in on the local machine. The user identifier is based on the Windows user SID that is assigned when the user account is created. If the user account is deleted, the objects previously stored using this storage type will not be available to the application.

Return Value

A value of True is returned if the object was copied. Otherwise, a value of False is returned and the **LastError** property will return the specific cause of the failure.

Remarks

The **Copy** method is used to create a copy of an existing storage object. It may be used to duplicate an object with a different label, or it may be used to copy the object to a new storage container type. For example, it can copy an object originally created in the **webStorageUser** container to a new object stored in the **webStorageMachine** container.

Copied objects are assigned their own unique ID and are not linked to one another. Any subsequent changes made to the original object will not affect the copied object. Attempting to copy an object to itself or another existing object will result in an error.

This method updates the current object. Various properties such as **ObjectId** and **ObjectLabel** will reflect the values associated with the new, copied object and not the original object it was copied from.

See Also

[Delete Method](#), [Move Method](#), [Rename Method](#)

Delete Method

Delete a stored object from the container.

Syntax

object.Delete(ObjectLabel)

Parameters

ObjectLabel

A string which specifies the label of the object that should be deleted.

Return Value

A value of True is returned if the object was deleted. Otherwise, a value of False is returned and the **LastError** property will return the specific cause of the failure.

Remarks

The **Delete** method is used to delete a stored object from the container. This method permanently deletes the storage object and its associated data from the server. Deleted objects cannot be recovered by the application. To remove all objects stored in the container, use the **DeleteAll** method.

See Also

[Copy Method](#), [DeleteAll Method](#), [Move Method](#), [Rename Method](#)

DeleteAll Method

Delete all stored objects in the container.

Syntax

object.DeleteAll

Parameters

None.

Return Value

A value of True is returned if all objects were deleted from the current container. Otherwise, a value of False is returned and the **LastError** property will return the specific cause of the failure.

Remarks

The storage container contains information for each of the objects that have been stored by the application. Each of these objects are associated with the application ID and the storage type that was specified when calling the **Open** method. The **DeleteAll** method instructs the server to remove all objects in the container, resetting it back to its initial state.

Exercise caution when using this method. The operation is immediate and the objects that are stored in the container are permanently deleted. They cannot be recovered by your application.

See Also

[Copy Method](#), [Delete Method](#), [Move Method](#), [Open Method](#), [Rename Method](#)

Exists Method

Determine if a specific stored object exists in the container.

Syntax

object.Exists(ObjectLabel)

Parameters

ObjectLabel

A string which specifies the label of the object.

Return Value

A value of True is returned if the object exists. Otherwise, a value of False is returned and the **LastError** property will return the specific cause of the failure.

Remarks

The **Exists** method is used to check for the existence of a stored object in the current container. If the object exists, various properties that return information about the current object, such as **ObjectId** and **ObjectSize** will be updated to return the metadata associated with the object.

Although storage object labels are similar to Windows file names, they are case-sensitive. When requesting information about an object, your application must specify the label name exactly as it was created. The object label cannot contain wildcard characters.

To obtain information about how much storage your applications are using and the total number of stored objects, use the **StorageUsed** and **StorageObjects** properties.

If you wish to enumerate all of the stored objects within the container, use the **FindFirst** and **FindNext** methods.

See Also

[ObjectId Property](#), [ObjectModified Property](#), [ObjectSize Property](#), [StorageObjects Property](#), [StorageUsed Property](#), [FindFirst Method](#), [FindNext Method](#)

FindFirst Method

Find the first stored object that matches a label or content type.

Syntax

`object.FindFirst( [MatchLabel], [ContentType] )`

Parameters

MatchLabel

A string which specifies the value to match against the object labels in the container. The string may contain wildcard characters similar to those use with the Windows filesystem. A "?" character matches any single character, and "*" matches any number of characters in the label. If this parameter is omitted or an empty string, all objects in the container will be matched.

ContentType

A string which specifies the content type of the objects to be enumerated. If this parameter is omitted or an empty string, the content type is ignored and all matching objects are returned. If a content type is specified, it must be a valid MIME media content type designated using the **type/subtype** nomenclature.

Return Value

A value of True is returned if a matching object exists. Otherwise, a value of False is returned and the **LastError** property will return the specific cause of the failure.

Remarks

The **FindFirst** method returns information about the first object that matches a given label, content type or both. It is used in conjunction with the **FindNext** method to enumerate all of the matching objects in the storage container.

If a matching object exists, various properties that return information about the current object, such as **ObjectId** and **ObjectSize** will be updated to return the metadata associated with the object.

See Also

[Exists Method](#), [FindNext Method](#)

FindNext Method

Find the next stored object that matches a label or content type.

Syntax

object.FindNext

Parameters

None.

Return Value

A value of True is returned if a matching object exists. If there are no more matching objects, or an error occurs, a value of False is returned and the **LastError** property will return the specific cause of the failure. If the **LastError** property returns a value of zero, then no error occurred and there are no additional matching objects.

Remarks

The **FindNext** method returns information about the next object that matches a given label, content type or both. This method may only be called after the **FindFirst** method is called, otherwise it will fail.

If a matching object exists, various properties that return information about the current object, such as **ObjectId** and **ObjectSize** will be updated to return the metadata associated with the object.

See Also

[Exists Method](#), [FindFirst Method](#)

GetData Method

Download the data in a stored object to a string or byte array buffer.

Syntax

object.GetData(*ObjectLabel*, *Buffer*, [*Length*])

Parameters

ObjectLabel

A string which specifies the label of the object that should be retrieved from the server.

Buffer

This parameter specifies the buffer that will contain the object data when the method returns. If the variable is a String type, then the data will be returned as a string of characters. This is the most appropriate data type to use if the object only contains text. If the object contains binary data, it is recommended that a Byte array variable be specified as the argument to this method.

Length

An optional integer argument that will contain the number of bytes copied into the buffer when the method returns.

Return Value

A value of True is returned on success. If an error occurs, a value of False is returned and the **LastError** property will return the specific cause of the failure..

Remarks

The **GetData** method transfers data from a stored object to the specified buffer. This method will cause the current thread to block until the data transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

When this method returns, various properties such as **ObjectId** and **ObjectLabel** will be updated to reflect the values associated with the object that was downloaded from the server.

See Also

[GetFile Method](#), [PutData Method](#), [PutFile Method](#), [OnProgress Event](#)

GetFile Method

Download the data in a stored object to a local file.

Syntax

object.GetFile(*LocalFile*, *ObjectLabel*)

Parameters

LocalFile

A string which specifies the name of the local file that will be created or overwritten with the contents of the storage object. If a path is not specified, the file will be created in the current working directory.

ObjectLabel

A string which specifies the label of the object that should be retrieved from the server.

Return Value

A value of True is returned on success. If an error occurs, a value of False is returned and the **LastError** property will return the specific cause of the failure..

Remarks

The **GetFile** method downloads data from a stored object to a local file. This method will cause the current thread to block until the data transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

When this method returns, various properties such as **ObjectId** and **ObjectLabel** will be updated to reflect the values associated with the object that was downloaded from the server.

See Also

[GetData Method](#), [PutData Method](#), [PutFile Method](#), [OnProgress Event](#)

Initialize Method

Initialize the control and validate the runtime license key.

Syntax

```
object.Initialize( [LicenseKey] )
```

Parameters

LicenseKey

An optional string value which specifies a runtime license key used to initialize the control. If the license key is omitted or passed as an empty string, a development license must be installed on the local system.

Return Value

A value of zero is returned if the control was initialized successfully. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

This method dynamically loads other system libraries and allocates thread local storage. In most cases, it is not necessary to call this method directly because it is automatically invoked when an instance of the control is created by the container. However, if the control is created dynamically using **CreateObject** or a similar method, this must be the first method that is called before you attempt to modify any property values or invoke other methods. Failure to initialize the control may result in subsequent errors and/or cause an exception to be raised.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the control will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the control was created.

If the control is being used within another DLL, it is important that you do not attempt to create an instance of the control or call the **Initialize** method from within the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is written in C++ and it is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for any static and global C++ objects and has the same restrictions.

Example

```
Set ipLocation = CreateObject("SocketTools.WebLocation.12")

nError = ipLocation.Initialize(strLicenseKey)
If nError > 0 Then
    MsgBox "Unable to initialize SocketTools component"
End
End If
```

See Also

[IsInitialized Property](#), [Uninitialize Method](#)

Move Method

Move a stored object to another container.

Syntax

```
object.Move( OldLabel, NewLabel [, StorageType] )
```

Parameters

OldLabel

A string which specifies the label of the object that should be moved.

NewLabel

A string which specifies the new label for the object being moved.

StorageType

A numeric value that identifies the storage container type. One of the following values should be specified. If this parameter is omitted, the object will be moved within the current container.

Value	Description
webStorageGlobal	Global storage. Objects stored using this storage type are available to all users. Any changes made to objects using this storage type will affect all users of the application. Unless there is a specific need to limit access to the objects stored by the application to specific domains, local machines or users, it is recommended that you use this storage type when creating new objects.
webStorageDomain	Local domain storage. Objects stored using this storage type are only available to users in the same local domain, as defined by the domain name or workgroup name assigned to the local system. If the domain or workgroup name changes, objects previously stored using this storage type will not be available to the application.
webStorageMachine	Local machine storage. Objects stored using this storage type are only available to users on the same local machine. The local machine is identified by unique characteristics of the system, including the boot volume GUID. Objects previously stored using this storage type will not be available on that system if the boot disk is reformatted.
webStorageUser	Current user storage. Objects stored using this storage type are only available to the current user logged in on the local machine. The user identifier is based on the Windows user SID that is assigned when the user account is created. If the user account is deleted, the objects previously stored using this storage type will not be available to the application.

Return Value

A value of True is returned if the object was moved. Otherwise, a value of False is returned and the **LastError** property will return the specific cause of the failure.

Remarks

The **Move** method is used to move an existing storage object to a new container. For example, it can move an object originally created in the **webStorageUser** container to the **webStorageMachine** container. Using this method to move an object within the same container is effectively the same as calling the **Rename** method.

This method updates the current object. Various properties such as **ObjectId** and **ObjectLabel** will reflect the values associated with the object which has been moved.

See Also

[Copy Method](#), [Delete Method](#), [Rename Method](#)

Open Method

Open a storage container.

Syntax

object.Open([*Appld*], [*StorageType*], [*Timeout*])

Parameters

Appld

A string which specifies the application ID for the storage container. The application ID is a string that uniquely identifies the application and can only contain letters, numbers, the period and the underscore character. If this parameter is omitted or an empty string, the default identifier

SocketTools.Storage.Default will be used.

StorageType

A numeric value that identifies the storage container type. One of the following values should be specified. If this parameter is omitted, global storage will be used by default.

Value	Description
webStorageGlobal	Global storage. Objects stored using this storage type are available to all users. Any changes made to objects using this storage type will affect all users of the application. Unless there is a specific need to limit access to the objects stored by the application to specific domains, local machines or users, it is recommended that you use this storage type when creating new objects.
webStorageDomain	Local domain storage. Objects stored using this storage type are only available to users in the same local domain, as defined by the domain name or workgroup name assigned to the local system. If the domain or workgroup name changes, objects previously stored using this storage type will not be available to the application.
webStorageMachine	Local machine storage. Objects stored using this storage type are only available to users on the same local machine. The local machine is identified by unique characteristics of the system, including the boot volume GUID. Objects previously stored using this storage type will not be available on that system if the boot disk is reformatted.
webStorageUser	Current user storage. Objects stored using this storage type are only available to the current user logged in on the local machine. The user identifier is based on the Windows user SID that is assigned when the user account is created. If the user account is deleted, the objects previously stored using this storage type will not be available to the application.

Timeout

The number of seconds that the client will wait for a response before failing the operation. If this argument is not specified, the value of the **Timeout** property will be used as the default.

Return Value

A value of **True** is returned if the storage container was opened. Otherwise, a value of **False** is returned and the **LastError** property will return the specific cause of the failure.

Remarks

The **Open** method opens the specified storage container and requests an access token for the application. This method that must be called prior to accessing any stored objects.

The application ID is a string that uniquely identifies the application requesting the access and must have been previously registered with the server by calling the **RegisterId** method. If the **AppId** parameter is omitted or an empty string, the a default internal ID will be used which is allocated for each storage account. You can use this default ID if you wish to share data between all of the applications you create.

The storage type specifies the type of container that objects will be stored in. In most cases, we recommend using **webStorageGlobal** which means that stored objects will be accessible to all users of your application. However, you can limit access to the stored objects based on the local domain, local machine ID or the current user SID.

If you specify anything other than global storage, objects can be orphaned if the system configuration changes. For example, if **webStorageMachine** is specified, the objects that are stored there can only be accessed from that computer system. If the system is reconfigured (for example, the boot volume formatted and Windows is reinstalled) the unique identifier for that system will change and the previous objects that were stored by your application will no longer be accessible.

It is advisable is to store critical application data and configuration information in the **webStorageGlobal** container and use other non-global storage containers for configuration information that is unique to that system and/or user which is not critical and can be easily recreated.

See Also

[AppId Property](#), [StorageType Property](#), [Timeout Property](#), [Close Method](#), [RegisterId Method](#)

PutData Method

Upload the data in a string or byte array buffer to the storage container.

Syntax

```
object.PutData( ObjectLabel, Buffer, [Length], [ContentType], [Attributes] )
```

Parameters

ObjectLabel

A string which specifies the label of the object that should be uploaded to the server. If an object with the same label already exists, it will be replaced with the contents of the buffer.

Buffer

This parameter specifies the buffer that contains the object data to be stored. If the variable is a String type, then the data will be stored as text. If the buffer contains binary data, the buffer must be specified as a Byte array.

Length

An optional integer argument that specifies the number of bytes to be stored. If this parameter is omitted, the length is determined by the length of the string or size of the byte array buffer provided by the caller.

ContentType

An optional string argument that identifies the contents of the buffer being stored. If this parameter is omitted, or specifies a zero-length string, the method will attempt to automatically determine the content type based on the object label and the contents of the buffer.

Attributes

An optional integer argument which specifies the attributes associated with the storage object. This value can be a combination of one or more of the following bit flags using a bitwise OR operation. If this parameter is omitted, the default attribute **webObjectNormal** will be used.

Value	Description
webObjectNormal	A normal object that that can be read and modified by the application. This is the default attribute for new objects that are created by the application.
webObjectReadOnly	A read-only object that can only be read by the application. Attempts to modify or replace the contents of the object will fail. Read-only objects can be deleted.
webObjectHidden	A hidden object. Objects with this attribute are not returned when enumerated using the FindFirst and FindNext methods. The object can only be accessed directly when specifying its label.

Return Value

A value of True is returned on success. If an error occurs, a value of False is returned and the **LastError** property will return the specific cause of the failure..

Remarks

The **PutData** method uploads the contents of a buffer to the current storage container. If an object exists with the same label, it will be replaced. During the transfer, the **OnProgress** event will fire

periodically, enabling the application to update any user interface objects such as a progress bar.

Although storage object labels are similar to Windows file names, they are case-sensitive. When requesting information about an object, your application must specify the label name exactly as it was created using this method. The object label cannot contain wildcard characters.

If the label identifies an object that already exists in the container, and that object was created with the **webObjectReadOnly** attribute, this method will fail. To replace a read-only object, the application must explicitly move, rename or delete the existing object.

If a content type is provided, it must specify a valid MIME media type and subtype. For example, normal text has a content type of **text/plain** while XML-formatted text would have a content type of **text/xml**. Data that contains unstructured binary data is typically identified as **application/octet-stream**. If you do not specify a content type, an appropriate content type will be determined automatically based on the label and the contents of the buffer.

If you wish to upload the contents of a file, use the **PutFile** method.

When this method returns, various properties such as **ObjectId** and **ObjectLabel** will be updated to reflect the values associated with the object that was created or replaced on the server.

See Also

[GetData Method](#), [GetFile Method](#), [PutFile Method](#), [OnProgress Event](#)

PutFile Method

Upload a local file to the current storage container.

Syntax

object.PutFile(*LocalFile*, *ObjectLabel*, [*ContentType*], [*Attributes*])

Parameters

LocalFile

A string which specifies the name of the local file that will be uploaded to the current storage container. If a path is not specified, the file will be opened in the current working directory.

ObjectLabel

A string which specifies the label of the object that should be created. If an object with the same label already exists, it will be replaced with the contents of the file.

ContentType

An optional string argument that identifies the contents of the file being stored. If this parameter is omitted, or specifies a zero-length string, the method will attempt to automatically determine the content type based on the file name and contents.

Attributes

An optional integer argument which specifies the attributes associated with the storage object. This value can be a combination of one or more of the following bit flags using a bitwise OR operation. If this parameter is omitted, the default attribute **webObjectNormal** will be used.

Value	Description
webObjectNormal	A normal object that that can be read and modified by the application. This is the default attribute for new objects that are created by the application.
webObjectReadOnly	A read-only object that can only be read by the application. Attempts to modify or replace the contents of the object will fail. Read-only objects can be deleted.
webObjectHidden	A hidden object. Objects with this attribute are not returned when enumerated using the FindFirst and FindNext methods. The object can only be accessed directly when specifying its label.

Return Value

A value of True is returned on success. If an error occurs, a value of False is returned and the **LastError** property will return the specific cause of the failure..

Remarks

The **PutFile** method uploads the contents of a file to the current storage container. If an object exists with the same label, it will be replaced. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

Although storage object labels are similar to Windows file names, they are case-sensitive. When requesting information about an object, your application must specify the label name exactly as it was created using this method. The object label cannot contain wildcard characters.

If the label identifies an object that already exists in the container, and that object was created with the

webObjectReadOnly attribute, this method will fail. To replace a read-only object, the application must explicitly move, rename or delete the existing object.

If a content type is provided, it must specify a valid MIME media type and subtype. For example, normal text has a content type of **text/plain** while XML-formatted text would have a content type of **text/xml**. Data that contains unstructured binary data is typically identified as **application/octet-stream**. If you do not specify a content type, an appropriate content type will be determined automatically based on the file name and contents.

If you wish to upload the contents of a string or byte array, use the **PutData** method.

When this method returns, various properties such as **ObjectId** and **ObjectLabel** will be updated to reflect the values associated with the object that was created or replaced on the server.

See Also

[GetData Method](#), [GetFile Method](#), [PutData Method](#), [OnProgress Event](#)

RegisterId Method

Register a new application identifier with the storage service.

Syntax

object.RegisterId (*ApplId*)

Parameters

ApplId

A string which identifies the application requesting access. If the application ID contains illegal characters, the method will fail. See the remarks below on the recommended method for identifying your application.

Return Value

A value of True is returned if the application ID was registered successfully. Otherwise, a value of False is returned and the **LastError** property will return the specific cause of the failure.

Remarks

The **RegisterId** method registers an application ID with the server which uniquely identifies the application that is requesting access to the storage container. The ID must only consist of ASCII letters, numbers, the period and underscore character. Whitespace characters and non-ASCII Unicode characters are not permitted. The maximum length of an application ID string is 63 characters.

It is recommended that you use a standard format for the application ID that consists of your company name, application name and optionally a version number. For example:

- MyCompany.MyApplication
- MyCompany.MyApplication.1

It is important to note that with these two example IDs, although they are similar, they reference two different applications. Objects stored using the first ID will not be accessible using the second ID. If you want to store objects that should be shared between all versions of the application, it is recommended that you use the first form, without the version number. If you want to store objects that should only be accessible to a specific version of your application, then it is recommended that you use the second form that includes the version number.

It is safe to call this method with an application ID that was previously registered. If the provided application ID has already been registered, this method will succeed.

If you no longer wish to use an application ID you have previously registered, you can call the **UnregisterId** method. Exercise caution when unregistering an application. This will cause all objects stored using that ID to be deleted by the storage server. Once an application ID has been unregistered, the operation is permanent. Calling **UnregisterId** and then **RegisterId** again using the same ID will force the system to create new access tokens for your application. You will not be able to regain access to the objects that were previously stored using that ID.

The application ID is intended to be an application defined human-readable string that uniquely identifies your application. If you want to obtain the internal storage ID associated with your application, get the value of the **StorageId** property. The storage ID is a fixed-length string of letters and numbers guaranteed to be unique across all applications that you register.

It is not required for your application to create a unique application ID. Each storage account has a

default internal application ID named **SocketTools.Storage.Default**. This default ID is used if an application-defined ID is not provided to the **Open** method. It is intended to identify storage available to all applications that you create.

[AppId Property](#), [Open Method](#), [UnregisterId Method](#), [ValidateId Method](#)

Rename Method

Change the label of an existing storage object.

Syntax

`object.Rename( OldLabel, NewLabel )`

Parameters

OldLabel

A string which specifies the label of the object that should be moved.

NewLabel

A string which specifies the new label for the object being moved. An object with this label cannot already exist.

Return Value

A value of True is returned if the object was renamed. Otherwise, a value of False is returned and the **LastError** property will return the specific cause of the failure.

Remarks

The **Rename** method is used to change the label of an existing storage object within the current storage container. If you wish to move an object to a different container, use the **Move** method.

This method updates the current object. Various properties such as **ObjectId** and **ObjectLabel** will reflect the values associated with the object which has been renamed.

See Also

[Copy Method](#), [Delete Method](#), [Move Method](#)

Reset Method

Reset the internal state of the control.

Syntax

object.Reset

Parameters

None.

Return Value

None.

Remarks

The **Reset** method resets the internal state of the control. Property values are initialized to their internal defaults, open network connections will be closed and any handles allocated by the control will be released.

See Also

[Initialize Method](#), [Uninitialize Method](#)

Uninitialize Method

Uninitialize the control and release any system resources that were allocated.

Syntax

object.Uninitialize

Parameters

None.

Return Value

None.

Remarks

The **Uninitialize** method terminates any connection established by the control and resets the internal state of the control. This method is not typically used because any resources that have been allocated by an instance of the control will automatically be released when it is destroyed.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the control will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the control was created. An application should only call the **Uninitialize** method if it has explicitly called the **Initialize** method.

See Also

[Initialize Method](#)

UnregisterId Method

Unregister a previously registered application identifier.

Syntax

object.UnregisterId (*AppId*)

Parameters

AppId

A string which specifies the application ID to be deleted. If the application ID is a zero-length string or contains illegal characters, the method will fail.

Return Value

A value of True is returned if the application ID was deleted. Otherwise, a value of False is returned and the **LastError** property will return the specific cause of the failure.

Remarks

The **UnregisterId** method deletes the internal storage identifier associated with the application ID and revokes all access tokens that were granted for the application. This operation is immediate and permanent.

Exercise caution when using this method. This will permanently delete all objects that were stored for the specified application. Calling **UnregisterId** and then **RegisterId** again using the same ID will force the system to create new access tokens for your application. You will not be able to regain access to the objects that were previously stored using that ID.

This method cannot be used to unregister the default storage application identifier **SocketTools.Storage.Default**. If this ID is specified, the method will fail with an error indicating that the ID is invalid.

See Also

[AppId Property](#), [Open Method](#), [RegisterId Method](#), [ValidateId Method](#)

ValidateId Method

Check an application identifier to ensure it is valid and exists.

Syntax

*object.ValidateId (*AppId*)*

Parameters

AppId

A string which specifies the application ID to be validated. If the application ID is a zero-length string or contains illegal characters, the method will fail.

Return Value

A value of True is returned if the application ID is valid. Otherwise, a value of False is returned and the **LastError** property will return the specific cause of the failure.

Remarks

The **ValidateId** method is used to determine if the specified application identifier is valid and has been previously registered using the **RegisterId** method. The ID must only consist of ASCII letters, numbers, the period and underscore character. Whitespace characters and non-ASCII Unicode characters are not permitted. The maximum length of an application ID string is 63 characters.

See Also

[AppId Property](#), [Open Method](#), [RegisterId Method](#), [UnregisterId Method](#)

ValidateLabel Method

Validate an object label to ensure it uses allowed characters.

Syntax

object.**ValidateLabel** (*ObjectLabel*)

Parameters

ObjectLabel

A string which specifies the object label to be validated. This parameter cannot be a zero-length string.

Return Value

A value of True is returned if the object label is valid. Otherwise, a value of False is returned and the **LastError** property will return the specific cause of the failure.

Remarks

Object labels are similar to Windows file names, except they are case-sensitive. The maximum length of a label string is 511 characters. Leading and trailing whitespace (spaces, tabs, linebreaks, etc.) are ignored in label names.

Illegal characters include ASCII and Unicode control characters 0 through 31, single quotes (39), double quotes (34), less than symbol (60), greater than symbol (62), pipe (124), asterisk (42) and question mark (63). It is not possible to embed null characters in the label name.

Label names may contain forward slash (47) characters and backslash (92) characters, however it is important to note that objects are not stored in a hierarchical structure. An application can create its own folder-like structure to the labels it creates, but this structure is not imposed or enforced by the control.

Labels can contain Unicode characters which are internally encoded as UTF-8.

Web Storage Control Events

Event	Description
OnCancel	This event occurs when a storage operation is canceled
OnDownload	This event occurs when a stored object is downloaded
OnError	This event occurs when a control error occurs
OnProgress	This event occurs as a stored object is being transferred
OnTimeout	This event occurs when a storage operation times out
OnUpload	This event occurs when a stored object is uploaded

OnCancel Event

The **OnCancel** event is generated when a storage operation is canceled.

Syntax

Sub *object_OnCancel* ([*Index As Integer*])

Remarks

This event occurs when a storage operation, such as sending or receiving data, is canceled with the **Cancel** method.

See Also

[Cancel Method](#), [OnError Event](#), [OnTimeout Event](#)

OnDownload Event

The **OnDownload** event is generated when a storage object has been downloaded.

Syntax

```
Sub object_OnDownload( [Index As Integer], ByVal ObjectLabel As Variant, ByVal ObjectSize As Variant )
```

Remarks

The **OnDownload** event is generated when a stored object has been successfully downloaded using either the **GetData** or **GetFile** methods. When this event occurs, the transfer has completed successfully and the downloaded object becomes the current object for the session. Prior to this event, the **OnProgress** event will occur periodically which provides information about the progress of the data transfer.

The *ObjectLabel* argument contains the label of object that has been downloaded, and the *ObjectSize* parameter contains the size of the downloaded object in bytes. Other values, such as the object digest (hash) and content type, can be determined by getting the values of the relevant properties.

See Also

[GetData Method](#), [GetFile Method](#), [OnProgress Event](#)

OnError Event

The **OnError** event is generated when a control error occurs.

Syntax

```
Sub object_OnError ( [Index As Integer,] ByVal ErrorCode As Variant, ByVal Description As Variant )
```

Remarks

This event occurs when an error occurs during a control action. Errors not generated by the control itself, such as errors related to the programming language or general component errors, do not trigger this event.

The ***ErrorCode*** argument specifies the last error that has occurred. If the error is network related, the error code values returned by the control typically correspond to those returned by the standard Windows Sockets library.

The ***Description*** argument is a string that describes the error.

See Also

[LastError Property](#), [LastErrorString Property](#), [ThrowError Property](#)

OnProgress Event

The **OnProgress** event is generated during data transfer.

Syntax

Sub *object_OnProgress* ([*Index As Integer*], *ByVal ObjectLabel As Variant*, *ByVal BytesTotal As Variant*, *ByVal BytesCopied As Variant*, *ByVal Percent As Variant*)

Remarks

The **OnProgress** event is generated during the transfer of data between the application and storage server, indicating the amount of data exchanged. For transfers of large amounts of data, this event can be used to update a progress bar or other user-interface control to provide the user with some visual feedback. The arguments to this event are:

ObjectLabel

A string value that specifies the name of the object that is being uploaded or downloaded.

BytesTotal

A numeric value that specifies the total amount of data being transferred in bytes. This value may be zero if the control cannot determine the total amount of data that will be copied. If the total number of bytes is less than 2 GiB, the value will be a **Long** (32-bit) integer. For very large transfers, it will be a **Double** floating-point value.

BytesCopied

A numeric value that specifies the number of bytes that have been transferred between the client and server. If the number of bytes copied is less than 2 GiB, the value will be a **Long** (32-bit) integer. For very large transfers, it will be a **Double** floating-point value.

Percent

The percentage of data that's been transferred, expressed as an integer value between 0 and 100, inclusive.

This event is only generated when data is transferred using the **GetData**, **GetFile**, **PutData** or **PutFile** methods.

See Also

[TransferBytes Property](#), [TransferRate Property](#), [TransferTime Property](#), [GetData Method](#), [GetFile Method](#), [PutData Method](#), [PutFile Method](#)

OnTimeout Event

The **OnTimeout** event is fired when a storage operation times out.

Syntax

Sub *object_OnTimeout* ([*Index As Integer*])

Remarks

The **OnTimeout** event is generated when a storage operation, such as uploading or downloading an object, times out.

See Also

[Timeout Property](#), [OnCancel Event](#), [OnError Event](#)

OnUpload Event

The **OnUpload** event is generated when a storage object has been uploaded.

Syntax

```
Sub object_OnUpload( [Index As Integer], ByVal ObjectLabel As Variant, ByVal ObjectSize As Variant )
```

Remarks

The **OnUpload** event is generated when a stored object has been successfully uploaded using either the **PutData** or **PutFile** methods. When this event occurs, the transfer has completed successfully and the downloaded object becomes the current object for the session. Prior to this event, the **OnProgress** event will occur periodically which provides information about the progress of the data transfer.

The ***ObjectLabel*** argument contains the label of object that has been downloaded, and the ***ObjectSize*** parameter contains the size of the downloaded object in bytes. Other values, such as the object digest (hash) and content type, can be determined by getting the values of the relevant properties.

WebView Control

The SocketTools WebView ActiveX control provides an embedded Chromium-based web browser that can be integrated into Visual Basic, Visual C++, Delphi, and other development environments that support ActiveX components. The control is implemented with the Microsoft Edge WebView2 runtime, exposing a simple, property-based interface and familiar COM events for handling navigation, scripting, and user interaction.

Reference

- [Properties](#)
- [Methods](#)
- [Events](#)
- [Error Codes](#)

Control Information

File Name	CSHTMX12.OCX
Version	12.0.3024.1286
ProgID	SocketTools.WebView.12
ClassID	B9925327-BDFA-467B-9E1A-FC24A78C1866
Threading Model	Apartment
Help File	CST12CTL.CHM
Dependencies	None

Overview

The SocketTools WebView control is designed to be easy to use with minimal setup, while still exposing the most common features developers need. You can load and display web pages, navigate programmatically, execute JavaScript, exchange messages with embedded scripts, and save the current content to disk. It automatically manages its underlying WebView2 environment and simplifies many common tasks. Events are available to handle common browser actions, such as navigation, focus changes, accelerator key handling, history changes, script execution results, and custom messages.

The WebView control is a visual control designed to be placed on a form. It integrates seamlessly with Visual Basic 6 and other classic ActiveX compatible containers, providing many of the common stock properties used to customize the display and behavior of the control. The control makes it possible to embed a modern, standards-compliant web browser into legacy applications with only a few lines of code, without requiring direct use of the complex WebView2 COM interfaces.

Applications are not limited to navigating to external websites. You can dynamically generate HTML content within your program and load it directly into the browser, making it possible to render reports, status pages, or other application data without creating temporary files. The browser also supports displaying local content using **file://** URLs, including HTML, images, PDF documents, and other formats that WebView2 can natively render. This makes it easy to blend remote and local resources within the same user interface.

When connecting to web servers, the control uses the underlying WebView2 runtime and supports

modern versions of HTTP, including HTTP/1.1, HTTP/2, and HTTP/3 where available. Connections are secured with Transport Layer Security (TLS), with support for TLS 1.2 and TLS 1.3 by default, and certificate validation is performed automatically by the runtime. This ensures that applications embedding the browser inherit the same security standards as Microsoft Edge, including enforcement of current best practices for encryption and certificate handling.

Requirements

The end-user system must have the current version of the Edge WebView2 Runtime installed. On Windows 11 and Windows 10 version 2004 (build 19041) and later, the runtime is considered part of the operating system and is updated automatically. On earlier platforms such as Windows 7, Windows 8, and Windows 10 builds prior to 19041, you may need to redistribute or install the WebView2 runtime separately. The control provides properties which can tell you if the runtime is installed and what version is available.

The SocketTools ActiveX Edition components are self-registering controls that are compatible with any programming language that supports the Component Object Model (COM) and the ActiveX control specification. If you are using Visual Basic 6.0, Service Pack 6 (SP6) is required. We recommend installing all available updates for your development tools. Although the Visual Basic 6.0 runtime is supported on Windows 11, the IDE itself is no longer officially supported by Microsoft. Legacy IDEs and compilers may also require elevated (administrator) privileges to run properly.

The ActiveX controls are supported on Windows 7, Windows Server 2008 R2, and later versions of both desktop and server editions of Windows. For Windows 7, Service Pack 1 (SP1) is the minimum requirement. For Windows 8 systems, the 8.1 update must be installed. On ARM-based platforms, the minimum supported version is Windows 10 build 1709.

SocketTools includes components for both 32-bit (x86) and 64-bit (x64) Windows platforms. All modern versions of Windows are 64-bit, but we continue to include 32-bit components for compatibility with legacy development tools such as Visual Basic 6.0. We also provide native ARM64 ActiveX controls for systems running Windows on ARM. Note that 32-bit applications on ARM run using x86 emulation, and Microsoft no longer supports native ARM32 applications.

If you are using VBScript, Visual Basic for Applications (VBA), or another scripting environment on an ARM-based system, be aware that 64-bit hosts will require ARM64 components, while 32-bit hosts will use x86 components under emulation. This includes applications created with Visual Basic 6.0. To reduce deployment complexity and avoid confusion, SocketTools does not include ARM32 ActiveX controls in its standard redistribution packages but they are available on request for legacy or specialized scenarios.

Distribution

When you distribute an application that uses this control, you can either install the file in the same folder as your application executable or as a shared component in the appropriate system folder. If you install the control in the system folder, it is important that you distribute the correct version for the target platform and it must be registered. If you install the control in the same folder as your executable, it is recommended that you use registration-free activation or COM redirection to ensure that the correct version of the control is loaded by the application.

In addition to the SocketTools control, the WebView2 Runtime must be present on the target system. On current versions of Windows 10 and Windows 11 the runtime is treated as part of the operating system and is updated automatically. On earlier platforms, you may need to redistribute or install the runtime using Microsoft's evergreen installer. We recommend always using the evergreen runtime rather than the fixed version, as it ensures security updates and feature improvements are delivered through Windows Update without requiring changes to your application.

The WebView2 Runtime is available as a separate download from Microsoft. For current links and redistribution guidelines, please refer to the SocketTools knowledge base or Microsoft's official documentation.

WebView Properties

Property	Description
AllowMessages	Enables message passing between the host and the current page.
AllowNavigation	Determines whether the control is allowed to navigate to new URLs.
AllowScripting	Enables JavaScript execution in the page. Disabling this can negatively impact most modern websites.
AllowZoom	Allows user zoom in and out using the keyboard interface, but does not impact programmatic zoom.
Appearance	Sets the visual appearance of the control's frame and does not affect page rendering.
AutoFill	Allows the browser to store and suggest form data.
BackColor	Background color used behind the page and during initial rendering.
BorderStyle	Specifies the window border style for the control and does not change page layout.
BrowserVersion	Returns a string which identifies the WebView2 runtime version used by this instance.
CanGoBack	Determines if there is a previous page in the navigation history.
CanGoForward	Determines if there is a next page in the navigation history.
Certificate	Returns information about the TLS server certificate for the last secure navigation.
ContentType	Returns the content type from the last response, preserved until the next navigation.
ContextMenu	Shows or hides the built-in right-click context menu inside the browser view.
DataFolder	Gets and sets the path to the user data folder used by this instance.
DevTools	Enables access to the browser developer tools (F12).
DocumentText	Gets and sets the contents of the current page.
DocumentTitle	Returns the page title from the current document.
Enabled	Determines whether the control is enabled and the user can interact with the browser.
Encryption	Returns details about the current secure connection when available.
FilteredText	Returns the current document text without HTML formatting.
Focused	Indicates whether the embedded browser currently has the input focus.
HttpStatus	Returns the HTTP status code from the last completed navigation.
InPrivate	Enables or disables private browsing for the current session.
IsInitialized	Determines if the environment and core control have been successfully created.
IsMuted	Determines if audio playback has been muted on the current page.
IsNavigating	Determines if a navigation is in progress prior to completion or cancellation.
Language	Gets and sets the language used to display context menus and dialogs in the browser.
LastError	returns a pointer to a numeric error code which specifies the most recent error condition.
LastErrorString	returns a pointer to a descriptive message for the most recent error condition.
LocalFile	Returns the full path to a local file displayed in the browser if applicable.
Normalize	Determines if URLs are normalized and validated before navigation.
Redirected	Indicates whether the last navigation followed one or more HTTP redirects.
RuntimeAvailable	Determines whether the Microsoft Edge WebView2 runtime is available on the system.
SavePasswords	Allows the browser to offer to save and auto-fill website passwords.
Secure	Determines if the current page was retrieved securely with no security warnings.

SecurityLevel	Returns the overall security level for the current page.
StatusBar	Determines if the browser shows status text in the bottom-left corner.
Timeout	Gets and sets a navigation timeout period in seconds. A value of zero uses the browser's default behavior.
Url	Gets or sets the current browser address. Setting this property initiates navigation to the specified URL.
UserAgent	Gets or sets the user-agent string used for requests made by this instance.
UserInitiated	Indicates whether the last navigation resulted from a user gesture rather than a script.
Version	Gets the current version of the control.
ZoomLevel	Gets or sets the current zoom factor, applying page scaling without changing layout.

AllowMessages Property

Enables message passing between the host and the current page.

Syntax

object.AllowMessages [= *value*]

Remarks

The **AllowMessages** property enables communication between the web page and the host application through the **window.chrome.webview.postMessage** API. This allows JavaScript running in the page to send messages back to your application, enabling advanced integration scenarios. If disabled, such messages are blocked and the corresponding events will never occur in your host code. This is commonly enabled when embedding custom HTML user interfaces that need to exchange data with the native application.

Data Type

Boolean

See Also

[AllowNavigation Property](#), [AllowScripting Property](#), [AllowZoom Property](#), [Execute Method](#), [PostWebMessage Method](#), [MessageReceived Event](#)

AllowNavigation Property

Determines whether the control is allowed to navigate to new URLs.

Syntax

object.AllowNavigation [= *value*]

Remarks

The **AllowNavigation** property determines if the user can navigate beyond the initial page loaded by the control.

If this property is False, the control restricts navigation after the initial page has loaded and attempts to navigate beyond this initial page will automatically be canceled. This is useful for scenarios like embedded help viewers, dashboards, or authentication windows where you want to confine the user to a specific site or document.

Data Type

Boolean

See Also

[AllowMessages Property](#), [AllowScripting Property](#), [AllowZoom Property](#), [Navigate Method](#), [NavigationCompleted Event](#), [NavigationStarting Event](#)

AllowScripting Property

Determines if JavaScript execution is permitted in the browser.

Syntax

object.AllowScripting [= *value*]

Remarks

This property enables or disables scripting in the browser and is enabled by default.

Nearly all modern websites depend on JavaScript, so setting this property to **False** will significantly limit what pages can display or function correctly. However, for controlled content where scripting is unnecessary or potentially unsafe, disabling this can enforce a higher level of security and prevent active content from running.

Some other options, such as receiving messages from the web application requires scripting to be enabled. If your application is only displaying local, static HTML content then you can set this property to False.

Data Type

Boolean

See Also

[AllowMessages Property](#), [AllowNavigation Property](#), [AllowZoom Property](#), [Execute Method](#), [PostWebMessage Method](#), [MessageReceived Event](#)

AllowZoom Property

Enables user zoom control using the keyboard interface.

Syntax

object.AllowZoom [= *value*]

Remarks

The **AllowZoom** property enables zoom support through keyboard and mouse input (Ctrl+Plus, Ctrl+Minus, Ctrl+Mouse Wheel). With this enabled, end users can adjust the document's scaling factor directly. When disabled, zooming is locked at 100%, ensuring that the page is always displayed at its natural size. This can be useful in applications where layout fidelity is important and user scaling could cause unexpected clipping or misalignment.

The application can change the zoom level for the current page using the **ZoomLevel** property regardless of this property value.

Data Type

Boolean

See Also

[ZoomLevel Property](#), [ZoomIn Method](#), [ZoomOut Method](#)

Appearance Property

Sets the visual appearance of the control's frame.

Syntax

object.**Appearance** [= *value*]

Remarks

The **Appearance** property sets whether the control edge is drawn with a flat style or has a sunken 3D style. It does not affect how content is rendered within the browser itself.

It may be set to one of the following values:

Value	Description
vbAppearanceFlat	The edge is drawn using a flat style.
vbAppearance3D	the border is drawn using a sunken edge style.

Data Type

Integer (Int32)

See Also

[BackColor Property](#), [BorderStyle Property](#), [Enabled Property](#)

AutoFill Property

Determines whether the browser can store and suggest form data.

Syntax

object.**AutoFill** [= *value*]

Remarks

The **AutoFill** property enables automatic saving of credentials in the runtime's password store. When this property is set, the control prompts to save usernames and passwords entered in forms, making them available for later autofill. While convenient for end users, applications embedding the control may choose to disable this to avoid storing sensitive information on the client system, particularly in enterprise or shared environments.

Data Type

Boolean

See Also

[AllowNavigation Property](#), [AllowScripting Property](#), [AllowZoom Property](#), [ContextMenu Property](#), [DevTools Property](#), [SavePasswords Property](#)

BackColor Property

Sets the background color used behind the page and during initial rendering.

Syntax

`object.BackColor [= value ]`

Remarks

The **BackColor** property returns the current background color for the control. Setting the property changes the color to the specified value. This value does not affect page transparency and it is important to note that this setting does not override the background defined by the currently loaded page. If the page specifies its own background color or image, that content will take precedence and may obscure the configured color. For example, setting the background to white will not force web pages to appear white unless the page itself has transparent regions.

Colors are RGB (Red Green Blue) values which range from 0 to 16,777,215 (&HFFFFFF). The high byte of a number in this range equals 0; the lower 3 bytes, from least to most significant byte, determine the amount of red, green, and blue, respectively. The red, green, and blue components are each represented by a number between 0 and 255 (&HFF). If the high byte isn't 0, the control uses the system colors, as defined in the user's Control Panel settings.

The following table lists the standard system color values and the Control panel settings that they correspond to:

Color Value	Definition	Control Panel Setting
80000000h	Scrollbar background	
80000001h	Desktop	Desktop
80000002h	Active window caption	Active Title Bar
80000003h	Inactive window caption	Inactive Title Bar
80000004h	Menu background	Menu
80000005h	Window background	Window
80000006h	Window frame	
80000007h	Menu text	Menu
80000008h	Window text	Window
80000009h	Window caption text	Active Title Bar
8000000Ah	Active window border	Active Window Border
8000000Bh	Inactive window border	Inactive Window Border
8000000Ch	Background color	Application Background
8000000Dh	Items selected in a control	Selected Items
8000000Eh	Text of items selected in a control	Selected Items
8000000Fh	Face shading on push buttons	
80000010h	Edge shading on push buttons	
80000011h	Disabled text	

80000012h	Text on push buttons	Caption Buttons
80000013h	Text color for an inactive caption	Inactive Title Bar
80000014h	Highlight color for buttons	
80000015h	Dark color for 3D display elements	
80000016h	Light color for 3D display elements	
80000017h	Text color for ToolTip controls	ToolTip
80000018h	Background color for ToolTip controls	ToolTip

Data Type

Integer (Int32)

See Also

[Appearance Property](#), [BorderStyle Property](#), [Enabled Property](#)

BorderStyle Property

Determines whether a border is drawn around the edge of the control.

Syntax

object.BorderStyle [= *value*]

Remarks

The **BorderStyle** property can be used to change how a border is drawn around the edge of the control. This property does not affect how content is rendered within the browser.

This property may be set to one of the following values:

Value	Description
vbBSNone	No border will be drawn around the control.
vbFixedSingle	A single pixel border will be drawn around the control.

Data Type

Integer (Int32)

See Also

[Appearance Property](#), [BackColor Property](#), [Enabled Property](#)

BrowserVersion Property

Returns a string which identifies the WebView2 runtime version used by this instance.

Syntax

object.**BrowserVersion**

Remarks

The **BrowserVersion** property returns the version information for the installed Microsoft Edge WebView2 Runtime. This is the runtime that hosts the embedded browser control, and it is separate from the version of the Edge browser that may be installed on the system. This can be useful for diagnostics, logging, or when an application requires a specific minimum runtime version to support certain features. If the WebView2 Runtime is not installed or cannot be located, the function will fail and return an empty string.

Data Type

String

See Also

[IsInitialized Property](#) [RuntimeAvailable Property](#) [Version Property](#), [Initialize Method](#)

CanGoBack Property

Determines if there is a previous page in the navigation history.

Syntax

object.CanGoBack

Remarks

The **CanGoBack** property returns True if there is a previous page in the navigation history. This can be used to check if the **GoBack** method could change the current page.

Data Type

Boolean

See Also

[CanGoForward Property](#), [GoBack Method](#), [GoForward Method](#), [Navigate Method](#), [HistoryChanged Event](#)

CanGoForward Property

Determines if there is a next page in the navigation history.

Syntax

object.CanGoForward

Remarks

The **CanGoForward** property returns True if there is a next page in the navigation history. This can be used to check if the **GoForward** method could change the current page.

Data Type

Boolean

See Also

[CanGoBack Property](#), [GoBack Method](#), [GoForward Method](#), [Navigate Method](#), [HistoryChanged Event](#)

Certificate Property

Returns information about the TLS server certificate for the last secure navigation.

Syntax

object.Certificate

Remarks

The **Certificate** property returns a string which contains information about the security certificate for the current site. The certificate information is returned as a comma separated collection of name/value pairs. It includes the certificate issuer, subject, issue date and expiration date. If the site is not secure, this property will return an empty string.

The information returned reflects the most recent navigation state. During navigation, these values may be provisional. For example, a page may initially appear secure but later be downgraded to a warning state if mixed content is detected. Applications should not consider this value definitive until a **NavigationCompleted** event occurs.

For information about the security protocol and cipher suite used for the secure connection, use the **Encryption** property.

Data Type

String

See Also

[Encryption Property](#), [IsNavigating Property](#), [SecurityLevel Property](#), [NavigationCompleted Event](#), [SecurityChanged Event](#)

ContentType Property

Returns the content type from the last server response.

Syntax

object.ContentType

Remarks

The **ContentType** property returns the MIME type reported by the server in the **Content-Type** response header for the most recent navigation. This value reflects the server's indication of what kind of content is being delivered, such as "**text/html**", "**application/pdf**", or "**image/png**". The returned string is preserved until the next navigation begins, even if the document is cleared or headers are reset.

It is important to note that not all servers will provide a **Content-Type** header. Some intentionally omit this information in combination with a **X-Content-Type-Options: nosniff** header as a security measure to prevent the client from "sniffing" or inferring the type. In such cases, **ContentType** will return an empty string. Applications should be prepared for this scenario and not assume a value will always be available.

Data Type

String

See Also

[UserAgent Property](#), [GetFirstHeader Method](#), [GetHeader Method](#), [GetNextHeader Method](#),

ContextMenu Property

Enables the default right-click context menu provided by the browser.

Syntax

object.ContextMenu [= *value*]

Remarks

The **ContextMenu** property enables the default right-click context menu provided by the browser. Setting this property to True exposes commands such as Back, Forward, Reload, and View Source. In an embedded control, this may not always be appropriate since it can expose functionality you do not want available to users. A value of False suppresses the default context menu entirely.

Data Type

Boolean

See Also

[AllowNavigation Property](#), [AllowScripting Property](#), [AllowZoom Property](#), [AutoFill Property](#), [SavePasswords Property](#)

DataFolder Property

Gets and sets the path to the user data folder used by this instance.

Syntax

object.DataFolder [= *value*]

Remarks

The **User Data Folder** (UDF) is the WebView2 profile directory that Chromium uses to persist browsing state for this instance. It contains the browser cache, cookies, localStorage data, service worker state, visited link history, site permissions, and other profile data. Each *distinct* folder path corresponds to a distinct browser profile. Multiple WebView2 instances that point to the same folder will share the same profile (and therefore share cookies, storage, and authentication state). Using different folder paths isolates profiles.

The user data folder is chosen when the WebView instance is created and cannot be changed afterwards. You should set this property value in design mode or within an event handler for the **Initialize** event. This property cannot be changed after that point. If your application needs to switch profiles (for example, to use a different folder), you must destroy the current control instance and create a new one with the desired folder.

If your application does not specify a folder or uses an empty string as the folder path, the control creates a unique per-session folder under the current user's local profile. This is an *ephemeral profile* that is not intended to be reused across browser instances. By default, this temporary folder is removed when the control is unloaded; if the process terminates unexpectedly, the folder may remain and can be safely deleted later.

In contrast, specifying an explicit, persistent folder (for example, a subdirectory under **%LocalAppData%\WebView\YourApp**) gives you a shared profile that persists across sessions and can be reused by multiple WebView2 instances to enable single sign-on, shared cookies, and faster subsequent navigations due to caching. Use this approach when you want consistent, long-lived browser state.

The reported folder path is always an absolute, normalized local path. Environment variables in the path you supply at creation time are expanded; forward slashes are normalized to backslashes and relative names are resolved beneath the current user's local application data folder. The control rejects invalid or unsafe locations (e.g.: device names, system directories, UNC or extended path prefixes, or root drive targets) and will create intermediate directories as needed for valid paths.

Important: The user data folder is managed internally by the the WebView2 runtime, and your application should never attempt to modify, move, or delete any of the files it contains while a browser instance is active. The contents are in use by the rendering engine and interfering with them can result in data corruption or unexpected behavior. If you need to remove or relocate a profile, ensure that all browser instances using that folder have been completely closed. If you want to delete certain data, such as cookies or the browser history, use the functions provided specifically for that purpose.

You can check the value of this property at any time after the instance has been created to discover which profile directory is in use.

Data Type

String

See Also

[InPrivate Property](#), [Initialize Event](#)

DevTools Property

Enables the integrated developer tools interface.

Syntax

object.DevTools [= *value*]

Remarks

When the **DevTools** property is set to True, users can press standard shortcuts (such as F12) or use the context menu to open the developer tools window and inspect the page. For production applications, you may want to disable this to prevent end users from inspecting or modifying content. During development or debugging, enabling it provides the same diagnostic features found in Microsoft Edge.

Data Type

Boolean

See Also

[AllowNavigation Property](#), [AllowScripting Property](#), [AllowZoom Property](#), [AutoFill Property](#), [ContextMenu Property](#), [SavePasswords Property](#)

DocumentText Property

Sets or returns the contents of the current page.

Syntax

object.DocumentText [= *value*]

Remarks

The **DocumentText** property retrieves the HTML markup for the current document loaded in the browser. This includes the complete contents of the **<html>** element, such as the **<head>** and **<body>** sections, rather than just the visible text.

The text returned will reflect the current state of the document at the time the function is called. If the page has been dynamically modified by scripts after it was initially loaded, those changes will be included. This property should only be checked after navigation has completed. If called while a page is still loading, the results may be incomplete or empty. When the content is provided by a local file or string, the returned HTML will be the original content that was passed to the control. The returned text is raw HTML and may contain scripts, style definitions, and markup that are not directly suitable for display in a plain-text context.

If a blank page is currently being displayed, such as when navigating to **about:blank** or by setting the current document text to an empty string, this property can still return a value. Internally, the browser creates a blank page using the markup "**<html><head></head><body></body></html>**" and that is what this property will return.

Setting the value of this property replaces the currently displayed content with the specified HTML or plain text. If the text does not contain any markup, it will be wrapped in HTML as preformatted text and displayed using the default monospaced font. If it is an empty string, the browser will display a blank page. If the string is very large (over 256 KiB), the control will first write the text to a local temporary file and then instruct the browser to navigate to that file. This is done to work around limitations in the Edge WebView2 control when handling long inline strings. The temporary file will be automatically deleted when it is no longer needed.

Important: It is possible to embed markup that references images, scripts, or other resources located on the Internet. While this is supported, you should be aware of potential risks when combining local content with external resources. This can create mixed-content scenarios and introduce cross-origin or security issues. Applications that render untrusted content should avoid linking to remote resources and ensure that the HTML provided is properly validated.

Data Type

String

See Also

[DocumentTitle Property](#), [FilteredText Property](#), [Url Property](#), [Navigate Method](#), [NavigationCompleted Event](#)

DocumentTitle Property

Returns the title for the current page.

Syntax

object.DocumentTitle

Remarks

The **DocumentTitle** property returns the current title of the document loaded in the browser. This corresponds to the contents of the **<title>** element in the document's **<head>** section, if one is defined.

The title is not fixed at the time the page is first loaded. A script running in the document can modify the **<title>** element dynamically, and some web applications use this technique to reflect state changes (for example, to indicate new messages or status updates). Because of this, the value returned by this function may change over the lifetime of the page. If the document does not explicitly define a title, the function may return an empty string. Applications that display document titles should be prepared to handle this case.

If the current document does not have a title, this property will return an empty string. This is not uncommon if the **DocumentText** property is used to change the current document and the text does not contain HTML markup or does not include a **<title>** tag.

Data Type

String

See Also

[DocumentText Property](#), [FilteredText Property](#), [Navigate Method](#), [NavigationCompleted Event](#)

Enabled Property

Determines whether the control is enabled.

Syntax

object.Enabled [= *value*]

Remarks

The **Enabled** property returns True if the control has been enabled and will accept user input. If False, the control is disabled. When disabled, the browser will render the current document but will not accept user input.

Data Type

Boolean

See Also

[Appearance Property](#), [BackColor Property](#), [BorderStyle Property](#)

Encryption Property

Sets or returns information about the encryption used with a secure connection.

Syntax

object.Encryption

Remarks

The **Encryption** property returns a string which specifies the security protocol and cipher suite selected for a secure connection. For example, a typical value for a secure connection would be "**TLS 1.3 (AES_256_GCM)**" and can be used for logging and diagnostic purposes. If the connection is not secure, this property will return an empty string.

The information returned reflects the most recent navigation state. During navigation, these values may be provisional. For example, a page may initially appear secure but later be downgraded to a warning state if mixed content is detected. Applications should not consider this value definitive until a **NavigationCompleted** event occurs.

For information about the TLS certificate provided by the server, use the **Certificate** property.

Data Type

String

See Also

[Certificate Property](#), [IsNavigating Property](#), [SecurityLevel Property](#), [NavigationCompleted Event](#), [SecurityChanged Event](#)

FilteredText Property

Returns the current document text without HTML formatting.

Syntax

object.FilteredText

Remarks

The **FilteredText** property filters the HTML markup filtered from the document text and returns output suitable for display in text-only environments. HTML tags are removed and entities are converted to their canonical Unicode equivalent. When filtering markup from the text, the function will:

- Remove all leading and trailing whitespace from the text, including newlines.
- Remove script, style, and other non-visible or unsafe elements.
- Convert common tag structures, such as lists and headers, into readable plain text.
- Extract and filter hyperlinks and image alt text, ignoring internal links to other sections.
- Remove any embedded credentials in hyperlinks.
- Decode common HTML entities such as **&trade** and **&copy**, as well as numeric entities like **&#x20**.

The function will remove extraneous whitespace within the text, but will attempt to maintain the structure of ordered and unordered lists. It does not parse the style information or Javascript that may be included in the HTML content. If a paragraph uses a style that would normally prevent it from being rendered in a browser (e.g.: the visibility attribute set to "hidden"), it is ignored and the text will be included in the output. If there are sections which contain preformatted text, such as text inside **<pre>...</pre>** or **<code>...</code>** tags, individual line and paragraph breaks will be preserved.

This function will not remove Unicode characters from the input text. If the HTML markup includes any entities which are represented as Unicode, such as **&frac12**; which represents "½", they will be returned in the output string buffer as Unicode characters. If you are using this control in Visual Basic, this could result in characters which cannot be displayed by the standard controls such as **Label1** or **TextBox**. These controls attempt to convert Unicode to ANSI using the system locale, which can result in garbled or missing characters. To correctly display full Unicode text, you must use controls that support Unicode natively, such as those in the Microsoft Forms 2.0 Object Library (FM20.DLL) with appropriate font settings, or render the text using Windows API functions.

Data Type

String

See Also

[DocumentTitle Property](#), [FilteredText Property](#), [Url Property](#), [Navigate Method](#), [NavigationCompleted Event](#)

Focused Property

Indicates whether the embedded browser currently has the input focus.

Syntax

object.**Focused**

Remarks

The **Focused** property returns True if the browser control has input focus, otherwise it returns False.

Data Type

Boolean

See Also

[Enabled Property](#)

HttpStatus Property

Returns the HTTP status code from the last completed navigation.

Syntax

object.HttpStatus

Remarks

This property returns the HTTP status code from the server response associated with the last completed navigation. These codes are defined by the HTTP standard and indicate the outcome of the request:

- **100-199**: Informational responses indicating the request is in progress.
- **200-299**: Successful responses, with 200 (OK) being the most common.
- **300-399**: Redirects, such as 301 (Moved Permanently) or 302 (Found).
- **400-499**: Client errors, such as 403 (Forbidden) or 404 (Not Found).
- **500-599**: Server errors, such as 500 (Internal Server Error) or 503 (Service Unavailable).

It is important to note that this value is only meaningful once navigation has completed. During a series of redirects, the status code may change multiple times; the value returned will be from the final response that completed navigation. A return value of **0** indicates the HTTP status code is unavailable. It may also return zero when the browser has navigated to a local file or when HTML content has been supplied directly using the **DocumentText** property.

Data Type

Integer (Int32)

See Also

[DocumentText Property](#), [GetHeader Method](#), [Navigate Method](#), [NavigationCompleted Event](#)

InPrivate Property

Enables or disables private browsing for the current session.

Syntax

`object.InPrivate [= value ]`

Remarks

The **InPrivate** property returns whether the browser session is using private (incognito) browsing. If this property is True, the user profile is not persisted beyond the current session. Browsing and search history will not be preserved, all cookies are temporary, data entered in form fields will not be saved and passwords will not be stored. If the **DataFolder** property has been set to specify a folder path for the session profile, setting this property to True will cause the control to create a unique, temporary folder in that location. Any general location information used by the browser is cleared when the application is closed.

This property can only be set in design mode or from within the **Initialize** event. After an instance of the browser is created, attempting to change this property will result in an error.

Data Type

Boolean

See Also

[InPrivate Property](#), [Initialize Event](#)

IsInitialized Property

Determine if the control has been initialized.

Syntax

object.IsInitialized

Remarks

The **IsInitialized** property is used to determine if the current instance of the control has been initialized properly. Normally this is done automatically when the control is loaded, however there are circumstances where the control may not be able to initialize itself. If this property returns **False**, the application must call the **Initialize** method to initialize the control before performing any other operation.

The most common reason that the control may not initialize correctly is that no valid license key can be found or the license key that was provided is invalid. It may also indicate a problem with the system configuration or user access rights, such as not being able to load the required networking libraries or not being able to access the system registry.

Data Type

Boolean

See Also

[BrowserVersion Property](#), [RuntimeAvailable Property](#), [Initialize Method](#)

IsMuted Property

Determines if audio playback has been muted on the current page.

Syntax

object.IsMuted [= *value*]

Remarks

If the **IsMuted** property is set to True, the control is effectively muted and no sound is produced, regardless of the page content. Applications that need to enforce silent operation, such as monitoring dashboards, may want to use this to disable sound effects from the browser. This property may be toggled while the page is loaded. By default, this property is False which allows sounds to be played.

Data Type

Boolean

See Also

[ContextMenu Property](#), [Enabled Property](#), [StatusBar Property](#)

IsNavigating Property

Determines if a navigation is in progress prior to completion or cancellation.

Syntax

object.IsNavigating

Remarks

The **IsNavigating** property returns True if the browser is in the process of navigating to a new location, such as retrieving a document from a web server over the Internet. If the property returns False, navigation has completed. This can be used to check if certain properties, such as **Secure** or **Url** are definitive because the browser has completed navigation.

Data Type

Boolean

See Also

[Certificate Property](#), [Encryption Property](#), [Redirected Property](#), [SecurityLevel Property](#), [Url Property](#), [Navigate Method](#), [NavigationCompleted Event](#), [NavigationStarting Event](#)

Language Property

Gets and sets the language used to display context menus and dialogs in the browser.

Syntax

object.Language [= *value*]

Remarks

The **Language** property specifies an alternate language to use when the browser displays a context menu or dialogs. This value can be a standard language tag in BCP-47 format (such as "**en-US**") or it can be a string which specifies a hexadecimal Windows locale identifier (such as "**0x0409**"). It is recommended you use the language tag whenever possible, as Microsoft is deprecating the use of locale identifiers (LCIDs) and their associated APIs. If this property is an empty string, the browser will use the current default language for the local user.

This property can only be set in design mode or from within the **Initialize** event. After an instance of the browser is created, attempting to change this property will result in an error.

Data Type

String

See Also

[Initialize Event](#)

LastError Property

Gets and sets the last error that occurred on the control.

Syntax

object.LastError [= *value*]

Remarks

The **LastError** property can be read to determine the last error that occurred for this control. If a value is assigned to this property, it must either be zero to clear the error or a valid error code for the control.

Data Type

Integer (Int32)

See Also

[LastErrorString Property](#)

LastErrorString Property

Return a description of the last error to occur

Syntax

object.LastErrorString

Remarks

The **LastErrorString** returns a description of the last error that occurred. This can be used to display a meaningful error message to a user, rather than just the numeric value returned by the **LastError** property.

Data Type

String

See Also

[LastError Property](#)

LocalFile Property

Returns the full path to a local file displayed in the browser if applicable.

Syntax

object.LocalFile [= *value*]

Remarks

If the browser is displaying content from a local file, this property returns the full path to that file. Setting this property will cause the browser to load the local file and display the contents, similar to specifying a **file://** URL to the **Navigate** method.

If you assign a value to this property, you can enclose environment variables in percent (%) symbols and they will automatically be expanded. For example, you could provide a file path like **"%UserProfile%\Documents"** and it would be expanded to the current user's **Documents** folder.

Data Type

String

See Also

[Url Property](#), [Navigate Method](#)

Normalize Property

Determines if URLs are normalized and validated before navigation.

Syntax

object.Normalize [= *value*]

Remarks

The **Normalize** property determines how URLs are handled when assigned to the **Url** property or passed to the **Navigate** method. If this property is True, URLs will be normalized so that paths are percent-encoded as needed, duplicate slashes removed, and path traversal segments are collapsed. Query parameters will also be encoded while preserving normal query delimiters. Unicode host names will be encoded as their ASCII equivalent. If this property is False, the URL will be provided to the browser control as-is without normalization and encoding.

Data Type

Boolean

See Also

[Url Property](#), [Navigate Method](#), [NavigationCompleted Event](#), [NavigationStarting Event](#)

Redirected Property

Indicates whether the last navigation followed one or more HTTP redirects.

Syntax

object.Redirected [= *value*]

Remarks

The **Redirected** property returns True if the current page was redirected from the original URL. The value of this property is only valid after navigation has completed.

Data Type

Boolean

See Also

[SecurityLevel Property](#), [Url Property](#), [Navigate Method](#), [NavigationCompleted Event](#),
[NavigationStarting Event](#)

RuntimeAvailable Property

Determines whether the Microsoft Edge WebView2 runtime is available on the system.

Syntax

object.RuntimeAvailable

Remarks

The **RuntimeAvailable** property checks whether the Microsoft Edge WebView2 runtime is installed and meets the minimum required version for the control. If the runtime is available, the property returns **True**; otherwise, it returns **False**. Developers can check this property when the control is created dynamically, or from within the **Initialize** event, to ensure that the local system has the runtime installed.

On modern versions of Windows, the WebView2 runtime is included as part of the operating system and is serviced through Windows Update. However, on older or unsupported versions of Windows the runtime may not be present by default and must be installed separately. In these cases, your application needs to detect the missing runtime and prompt the user to install it.

The latest WebView2 runtime version officially supported on Windows 7 and Windows 8/8.1 is version 109.0.1518.140, released January 2023. After version 109, no further updates, new features, or fixes have been provided for those operating systems. Although this control supports Windows 7 and Windows 8, these platforms are not recommended because they no longer receive security updates for the browser.

Data Type

Boolean

See Also

[Initialize Method](#), [Initialize Event](#)

SavePasswords Property

Allows the browser to offer to save and auto-fill website passwords.

Syntax

object.SavePasswords [= *value*]

Remarks

When the **SavePasswords** property is set to True, the control prompts to save usernames and passwords entered in forms, making them available for later autofill. While convenient for end users, applications embedding the control may choose to disable this to avoid storing sensitive information on the client system, particularly in enterprise or shared environments. Setting this property to False prevents passwords from being saved.

If the **InPrivate** property is True or the **DataFolder** property has not been set to a folder where a user profile will be stored, this property has no persistent effect. Although the browser will prompt to save the password, that information will be automatically deleted when the application closes. Passwords are only saved when a user profile folder has been explicitly specified.

Data Type

Boolean

See Also

[AutoFill Property](#), [DataFolder Property](#), [InPrivate Property](#)

Secure Property

Determines if the current page was retrieved securely with no security warnings.

Syntax

object.Secure

Remarks

The **Secure** property returns **True** if the current page was retrieved using a secure connection. If the connection was not encrypted, or there was a problem with the server certificate, this property will return **False**. The value of this property reflects the most recent navigation state. During navigation, this value may change. For example, a page may initially appear secure but later be downgraded to a warning state if mixed content is detected. Applications should not consider this value definitive until a **NavigationCompleted** event occurs.

The **SecurityLevel** property provides more detailed information about the security of the page. If the **Secure** property returns **False**, it means the connection wasn't secure, but it doesn't provide any information as to what the underlying reason was. The **SecurityLevel** property can tell you if a secure protocol wasn't used, the site had an invalid certificate, the page contained mixed content, or it used weak encryption.

The **Certificate** and **Encryption** properties can provide more information about a secure connection.

Data Type

Boolean

See Also

[Certificate Property](#), [Encryption Property](#), [IsNavigating Property](#), [SecurityLevel Property](#), [NavigationCompleted Event](#), [SecurityChanged Event](#)

SecurityLevel Property

Returns the overall security level for the current page.

Syntax

`object.SecurityLevel`

Remarks

The **SecurityLevel** property returns the security level for the current page. It can be one of the following values:

Constant	Value	Description
webSecurityLevelUnknown	0	The security state could not be determined.
webSecurityLevelInsecure	1	The page was retrieved using plain HTTP or the site has an invalid certificate.
webSecurityLevelWarning	2	The page contains mixed content or only weak encryption is available.
webSecurityLevelNeutral	3	Local content or the browser is in a transitional/loading state.
webSecurityLevelSecure	4	The page was retrieved using HTTPS and the site has a valid certificate.

For a simple security check, the **Secure** property can determine if a page was retrieved using a secure, encrypted connection. If the property returns True, it means a secure connection was used and there were no problems with the server's certificate (e.g., the domain names match and the certificate hasn't expired). It is effectively the same as checking for a security level greater than **webSecurityLevelNeutral**.

For more detailed information about a secure connection, check the value of the **Certificate** and **Encryption** properties.

Data Type

Integer (Int32)

See Also

[Certificate Property](#), [Encryption Property](#), [IsNavigating Property](#), [NavigationCompleted Event](#), [SecurityChanged Event](#)

StatusBar Property

Determines if the browser shows status text in the bottom-left corner.

Syntax

object.StatusBar [= *value*]

Remarks

The **StatusBar** property can be used to enable or disable the status bar which appears at the bottom left corner of the browser control when the user hovers over a link. It provides basic feedback about navigation targets but has no interactive features. In a minimal UI, you may prefer to disable this so the embedded control presents only the rendered page. Regardless of this property, you can always check the current browser location using the **Url** property.

Data Type

DataType

See Also

[ContextMenu Property](#), [DevTools Property](#), [Url Property](#)

Text Property

Sets and returns the contents of the current page

Syntax

object.Text [= *value*]

Remarks

The **Text** property is an alias for the **DocumentText** property. Applications should use the **DocumentText** property to return or change the contents of the current page.

Data Type

String

See Also

[DocumentText Property](#), [DocumentTitle Property](#), [FilteredText Property](#), [Url Property](#), [Navigate Method](#), [NavigationCompleted Event](#)

Timeout Property

Gets and sets the amount of time to wait for the navigation to complete.

Syntax

object.Timeout [= *value*]

Remarks

Setting the **Timeout** property specifies the number of seconds to wait for the navigation to complete.

If the timeout period is set to zero, the control does not enforce its own timer and instead relies on the default timeouts implemented by the WebView2 engine. These built-in timeouts automatically handle conditions such as slow DNS resolution, stalled connections, or unreachable servers, and generally behave in the same way as the Microsoft Edge browser.

If a non-zero timeout period is specified, the control will cancel the navigation if the internal timer exceeds that value and the page has not finished loading. When this occurs, the navigation is stopped and a timeout error is reported through the standard navigation event notifications. This allows applications to fail fast in cases where a site is not responding, rather than waiting for the browser's adaptive timeouts to expire.

Note that specifying a very large timeout value will not force the browser to wait indefinitely. The WebView2 engine may still apply its own internal maximums and terminate the navigation earlier if it decides the request cannot succeed. Applications should select timeout values that balance responsiveness and reliability.

Data Type

Integer (Int32)

See Also

[Url Property](#), [Navigate Method](#), [NavigationCompleted Event](#), [NavigationStarting Event](#)

Url Property

Gets or sets the current browser address.

Syntax

object.Url [= *value*]

Remarks

The **Url** property returns the current Uniform Resource Locator string which is used by the control to access a resource on the server. URLs have a specific format which provides information about the server, port and resource:

[http|https]://hostname [:port] / resource [? parameters]

The first part of the URL is the protocol and will typically be **http**, or **https** if a secure connection is being used. Following the protocol, there is the name of the server to connect to, optionally followed by a port number. If no port number is given, then the default port for the protocol will be used. This is followed by the resource, which is usually a path to a file or script on the server. Parameters to the resource may also be specified, which are typically used as arguments to a program that is executed on the server.

Here are some common examples of URLs used to access resources on an HTTP server:

http://www.example.com/products/index.html

In this example, the server is `www.example.com` and the resource is `/products/index.html`.

The default port of 80 will be used to access the resource.

http://www.example.com:8080/index.html

In this example, the server is `www.example.com` and the resource is `/products/index.html`.

However, the client should connect to an alternative port number, in this case 8080.

https://www.example.com/order/confirm.php

In this example, the server is `www.example.com` and the resource is the script `/order/confirm.php`. Because the protocol is **https**, a secure connection on port 443 will be established.

If this property is assigned a value other than an empty string, the control will navigate to that address. You can also assign a local **file://** URL to this property and the control will display the contents of the file. If the user clicks on a link in the browser, this property will be updated to reflect the URL of the page that is currently being displayed. Note that this property value can change during navigation due to redirection.

Data Type

String

See Also

[LocalFile Property](#), [Redirected Property](#), [Secure Property](#), [SecurityLevel Property](#), [Navigate Method](#), [NavigationCompleted Event](#), [NavigationStarting Event](#)

UserAgent Property

Sets or returns the user-agent string used for requests made by this instance.

Syntax

`object.UserAgent [= value ]`

Remarks

The **UserAgent** property retrieves the current user-agent string used by this browser instance. This value is the exact string sent in the user-agent header of outgoing HTTP requests and is determined by the underlying Microsoft Edge WebView2 runtime unless explicitly changed. The returned value can be used for informational purposes, such as logging the client identity or displaying diagnostic information to the user. It is also useful if your application needs to preserve the default user-agent string before setting a custom one.

Setting this property changes the string that will be sent in the user-agent header for all subsequent HTTP requests made by this browser instance. This property should always be used to modify the user-agent header value; you should not set the header directly using the **SetHeader** method.

Applications may want to override the default user-agent in several scenarios:

- Requesting a mobile or tablet version of a site by providing a user-agent string that identifies as a mobile browser.
- Emulating a different browser for testing purposes.
- Including custom product tokens identifying the host application to the server.

The general format of a user-agent string follows the conventions described in RFC 9110:

User-Agent: product / version (comment) [product / version ...]

For example, a typical user-agent string might look like:

Mozilla/5.0 (Windows NT 10.0; Win64; x64) AppleWebKit/537.36 (KHTML, like Gecko) Chrome/140.0.0.0 Safari/537.36 Edg/140.0.0.0

This value is global to the control instance. Once changed, it will remain in effect until explicitly reset or until the browser control is destroyed. When setting a custom user-agent value, developers should ensure it is a syntactically valid string. Some websites may reject requests or provide degraded functionality if the value is malformed or omits key tokens.

If you want to change the user-agent string to identify your application, it is recommended that you append your application name and version to the default value.

Data Type

String

See Also

[GetHeader Method](#), [Navigate Method](#), [SetHeader Method](#)

UserInitiated Property

Returns whether the last navigation resulted from a user gesture rather than a script.

Syntax

object.**UserInitiated**

Remarks

The **UserInitiated** property returns True if the current navigation was due to a user clicking on a link or the applicaiton has explicitly navigated to a new location. If the property returns False, the navigation was due to a script running in the browser.

Data Type

Boolean

See Also

[Url Property](#), [Navigate Method](#), [NavigationCompleted Event](#), [NavigationStarting Event](#)

Version Property

Return the current version of the control.

Syntax

object.Version

Remarks

The **Version** property returns the current version of the object. This can be used by an application for validation purposes. The version returned is composed of four numbers, separated by periods. The first number is the major version number, the second number is the minor version number, the third is the build number and the fourth is the revision number.

Note that this property value is different from the version for the embedded Edge WebView2 browser control. The **BrowserVersion** property can be used to determine which version of the browser control is installed on the local system.

Data Type

String

See Also

[BrowserVersion Property](#), [IsInitialized Property](#), [RuntimeAvailable Property](#), [Initialize Method](#)

ZoomLevel Property

Sets or returns the current zoom factor, applying page scaling without changing layout.

Syntax

object.ZoomLevel [= *value*]

Remarks

The **ZoomLevel** property changes the zoom level of the current browser window to the specified percentage. A zoom level of **100** represents the default size with no scaling applied. Larger values magnify the content, while smaller values reduce it. The zoom percentage is constrained by the limits defined for the control. The minimum supported zoom level is **25** (25%) and the maximum is **400** (400%). If a value outside of this range is specified, it will be clamped to the nearest valid zoom level.

Changing the zoom level affects how the page content is displayed but does not alter the underlying document. This is equivalent to adjusting the zoom in a standard web browser. The new zoom level applies to the current browser instance and will remain in effect until it is changed again, or the control is destroyed.

The value of the **AllowZoom** property does not affect your ability to change the zoom level using this property.

Data Type

Integer (Int32)

See Also

[AllowZoom Property](#), [ZoomIn Method](#), [ZoomOut Method](#)

WebView Methods

Method	Description
AsyncExecute	Executes the specified script or command asynchronously in the context of the current document.
Cancel	Cancels the current navigation or script operation if one is in progress.
ClearCache	Clears the browser's in-memory and on-disk cache for the current profile.
ClearCookies	Removes all cookies or only session cookies stored by the current profile.
ClearHeaders	Removes any custom HTTP request headers that were previously set for this instance.
ClearHistory	Clears the browser navigation history, resetting the ability to go back or forward.
Execute	Executes the specified JavaScript synchronously in the current document and returns the result immediately.
GetFirstHeader	Begins enumeration of response headers returned from the last completed navigation and retrieves the first header name and value.
GetHeader	Retrieves the value of a specific response header by name from the last completed navigation.
GetNextHeader	Continues header enumeration, returning the next header name and value.
GoBack	Navigates to the previous page in the session history if one is available.
GoForward	Navigates to the next page in the session history if one is available.
Initialize	Initializes the control environment and attaches it to the host window.
Navigate	Loads the specified URL or local file into the browser control.
PostWebMessage	Sends a JSON-formatted message from the host application to scripts running inside the browser.
PrintDocument	Displays a print dialog and allows the user to print the currently loaded document.
Refresh	Reloads the current page, revalidating cached resources with the server if applicable.
Reload	Forces a complete reload of the current page.
Reset	Resets the browser instance by clearing its state and releasing cached document data.
SaveDocument	Saves the currently displayed document in a specified format such as HTML, PDF, MHTML, or image.
SetHeader	Sets the value of a specific request header to be included with the next navigation.
Uninitialize	Uninitializes the browser environment, detaching it from the host window and releasing resources.
ZoomIn	Increases the zoom level of the current document to the next higher preset value.
ZoomOut	Decreases the zoom level of the current document to the next lower preset value .

AsyncExecute Method

Executes the specified script or command asynchronously in the context of the current document.

Syntax

object.AsyncExecute(JavaScript)

Parameters

JavaScript

A string which specifies the JavaScript that should be executed in the context of the current page being viewed.

Return Value

Returns True if the method succeeds or False if the method fails.

Remarks

The **AsyncExecute** method evaluates a JavaScript expression within the context of the currently loaded page and returns the result asynchronously. Unlike **Execute**, this method does not block while waiting for the script to complete. Instead, the result is delivered through the **ScriptCompleted** event.

The script must be valid JavaScript and should not assume synchronous execution. Results are returned in the event handler which will provide you with the response in JSON-encoded form; for example, string values will be quoted. Because script execution is dispatched to the underlying WebView2 control, this function will fail if navigation is still in progress. Applications should always wait for the **NavigationCompleted** event before invoking script execution.

See Also

[Execute Method](#), [NavigationCompleted Event](#), [ScriptCompleted Event](#)

Cancel Method

Cancels the current navigation.

Syntax

object.Cancel

Parameters

None.

Return Value

None.

Remarks

The **Cancel** method cancels the current navigation. This is typically used inside an event handler, causing the navigation to stop. If the control is not in the process of navigating to a new page at the time that this method is called, it will have no effect. A canceled navigation will fire the **NavigationCompleted** event.

See Also

[Navigate Method](#), [Reset Method](#), [NavigationCompleted Event](#), [NavigationStarting Event](#)

ClearCache Method

Description of the method.

Syntax

object.ClearCache

Parameters

None.

Return Value

Returns True if the method succeeds or False if the method fails.

Remarks

This method will clear the browser cache for the current session. This can be useful if you wish to force the browser to reload content. If you have created the browser instance using a temporary data folder, or you have set the **InPrivate** property to True, the browser session will always start with a new user profile and will not contain any cached content.

See Also

[ClearCookies Method](#), [ClearHeaders Method](#), [ClearHistory Method](#), [DataFolder Property](#), [InPrivate Property](#)

ClearCookies Method

Removes all cookies or only session cookies stored by the current WebView profile.

Syntax

object.ClearCookies([*AllCookies*])

Parameters

AllCookies

A boolean parameter which specifies which cookies should be removed. If True, all cookies for the current profile will be removed. If False, only the current session cookies will be removed.

Return Value

Returns True if the method succeeds or False if the method fails.

Remarks

This method deletes cookies that have been created by the current WebView profile. If the **AllCookies** parameter is True, all stored cookies for every site are removed; if False, only the cookies associated with the current session are cleared. The effect is comparable to clearing cookies in a regular browser: login sessions, preferences, and other state information stored in cookies will no longer be available. This only affects the WebView's private user data folder and does not modify cookies stored by the user's standalone Edge browser.

If you have used the WebView browser to authenticate with one or more websites, calling this method will typically log you out of those sites and require you to re-authenticate. If you have created the browser instance using a temporary data folder, or you set the **InPrivate** property to True, no cookies will be preserved after the session ends.

See Also

[ClearCache Method](#), [ClearHeaders Method](#), [ClearHistory Method](#), [DataFolder Property](#), [InPrivate Property](#)

ClearHeaders Method

Removes any custom HTTP request headers that were previously set for this instance.

Syntax

object.ClearHeaders

Parameters

None.

Return Value

Returns True if the method succeeds or False if the method fails.

Remarks

This method deletes the custom request headers set with the **SetHeader** method and deletes the response headers returned by the previous navigation.

See Also

[ClearCache Method](#), [ClearCookies Method](#), [ClearHistory Method](#), [DataFolder Property](#), [InPrivate Property](#)

ClearHistory Method

Clears the browser navigation history, resetting the ability to go back or forward.

Syntax

object.ClearHistory

Parameters

None.

Return Value

Returns True if the method succeeds or False if the method fails.

Remarks

This method clears both the profile's stored browsing history and the navigation history for the current WebView instance. Internally, it uses the WebView2 profile APIs to remove stored history and related download entries, and then resets the back/forward navigation stack. The effect is similar to selecting clearing the browser history in a browser, where visited pages are removed from the user's history, and the in-memory list of sites you can go back or forward to is discarded.

See Also

[ClearCache Method](#), [ClearCookies Method](#), [ClearHeaders Method](#), [DataFolder Property](#), [InPrivate Property](#)

Execute Method

Executes the specified JavaScript synchronously in the current document and returns the result immediately.

Syntax

object.Execute(*JavaScript*, *Response*)

Parameters

JavaScript

A string which specifies the JavaScript that should be executed in the context of the current page being viewed.

Response

A string which will contain the response returned by the script, either as a JSON object or a JSON string value.

Return Value

Returns True if the method succeeds or False if the method fails.

Remarks

The **Execute** method evaluates a JavaScript expression within the context of the currently loaded page and returns the result synchronously. Unlike **AsyncExecute**, this method blocks while waiting for the script to complete. If the web page is non-responsive, this method will timeout after approximately two seconds. Applications should wait for the **NavigationCompleted** event before invoking script execution.

See Also

[AsyncExecute Method](#), [NavigationCompleted Event](#), [ScriptCompleted Event](#)

MethodName Method

Description of the method.

Syntax

`object.MethodName( Parameter1, Parameter2, [Parameter3], [Parameter4] )`

Parameters

Parameter1

A datatype argument which provides some information to the method.

Parameter2

A datatype argument which provides some information to the method.

Parameter3

An optional datatype argument which provides some information to the method.

Parameter4

An optional datatype argument which provides some information to the method.

Value	Description
controlOptionNone	A description of this constant which may be passed to the method
controlOptionOne	A description of this constant which may be passed to the method
controlOptionTwo	A description of this constant which may be passed to the method
controlOptionThree	A description of this constant which may be passed to the method

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **MethodName** method performs some action in the control.

Example

The following example demonstrates how to use the MethodName method:

Example code goes here

See Also

Properties, Methods, Events

GetFirstHeader Method

Begins enumeration of response headers returned from the last completed navigation and retrieves the first header name and value.

Syntax

object.GetFirstHeader(*HeaderName*, *HeaderValue*)

Parameters

HeaderName

A string buffer which will contain the name of the first header returned by the server.

HeaderValue

A string buffer which will contain the value of the first header returned by the server.

Return Value

Returns True if the method succeeds or False if the method fails.

Remarks

The response headers exposed by this method correspond to the most recent completed navigation for the specified browser instance. Callers typically use this method to start an enumeration and then call **GetNextHeader** repeatedly until it returns False to indicate there are no more headers to enumerate.

Header names are case-insensitive by definition. This method will usually return header names as lower-case values, but applications should never depend on the casing and should compare names case-insensitively. The header names and values are returned exactly as enumerated internally by the WebView2 control.

Some response headers can appear multiple times in a message. For list-valued headers (those defined by the HTTP specifications to be comma-joinable), the implementation may return a single entry with a comma-separated value (e.g., **Accept-Language**, **Cache-Control**, etc.). Other headers must not be combined; for example, each **Set-Cookie** header is returned as a separate name/value pair and will be seen multiple times during enumeration, each with a single cookie value. Code that depends on specific headers should be prepared for either a single combined value or multiple discrete occurrences of the same header name, depending on the header's semantics.

Enumeration reflects a snapshot of the headers for that response. Beginning a new navigation or calling **ClearHeaders** invalidates the current enumeration. Only one header enumeration can be active per browser instance at a time. This method cannot be called while the browser is in the process of navigating to a new location. It will also fail if the current document is a local file or if the document text was set dynamically using the **DocumentText** property. There are no response headers available in a local context.

See Also

[ClearHeaders Method](#), [GetHeader Method](#), [GetNextHeader Method](#)

GetHeader Method

Description of the method.

Syntax

object.GetHeader(*HeaderName*, *HeaderValue*)

Parameters

HeaderName

A string which specifies the header name.

HeaderValue

A string buffer which will contain the value of header associated with the header name when the method returns.

Return Value

Returns True if the method succeeds or False if the method fails.

Remarks

The **GetHeader** method retrieves the value of a specific HTTP response header returned by the server. Header names are matched in a case-insensitive manner, with leading and trailing whitespace automatically trimmed before comparison. If multiple values are present for the specified header name, the behavior depends on the type of header:

- For headers that must not be combined (such as **Set-Cookie** and **Proxy-Authenticate**), only the first value encountered is returned.
- For all other headers, multiple values are joined together and returned as a single comma-separated string, as defined by the HTTP specification.

For headers such as **Set-Cookie**, which may legitimately occur multiple times with distinct values, **GetHeader** will only return the first occurrence. If your application needs to process each value individually, you should use **GetFirstHeader** and **GetNextHeader** to enumerate all response headers rather than relying on this method.

Response headers are only available after navigation has completed. Calling this method while a navigation is still in progress, or when displaying local file or data content, will fail.

See Also

[ClearHeaders Method](#), [GetFirstHeader Method](#), [GetNextHeader Method](#)

GetNextHeader Method

Continues header enumeration, returning the next header name and value.

Syntax

object.GetNextHeader(*HeaderName*, *HeaderValue*)

Parameters

HeaderName

A string buffer which will contain the name of the next header returned by the server.

HeaderValue

A string buffer which will contain the value of the next header returned by the server.

Return Value

Returns True if the method succeeds or False if the method fails.

Remarks

This method continues the enumeration that was started when the **GetFirstHeader** method was called. Repeatedly call **GetNextHeader** until it returns False indicating there are no more header values to return.

This method cannot be called while the browser is in the process of navigating to a new location. It will also fail if the current document is a local file or if the document text was set dynamically using the **DocumentText** property. There are no response headers available in a local context.

See Also

[ClearHeaders Method](#), [GetFirstHeader Method](#), [GetHeader Method](#)

GoBack Method

Navigates to the previous page in the session history if one is available.

Syntax

object.GoBack

Parameters

None.

Return Value

Returns True if the method succeeds or False if the method fails.

Remarks

The **GoBack** method navigates the browser to the previous page in its session history, if one is available. This is equivalent to selecting the Back button in a standard web browser. If there is no previous entry in the history list, the method will succeed but no navigation will occur. The availability of backward navigation can be determined by handling the **HistoryChanged** event and checking the value of the **CanGoBack** property.

Calling **ClearHistory** will remove the session history for the browser instance. After the history has been cleared, calling **GoBack** will have no effect until new pages have been visited.

See Also

[CanGoBack Property](#), [CanGoForward Property](#), [GoForward Method](#), [Navigate Method](#), [HistoryChanged Event](#)

GoForward Method

Navigates to the next page in the session history if one is available.

Syntax

object.GoForward

Parameters

None.

Return Value

Returns True if the method succeeds or False if the method fails.

Remarks

The **GoForward** method navigates the browser to the next page in its session history, if one is available. This is equivalent to selecting the Forward button in a standard web browser.

If there is no forward entry in the history list, the method will succeed but no navigation will occur. The availability of forward navigation can be determined by handling the **HistoryChanged** event and checking the **CanGoForward** property.

Calling **ClearHistory** will remove the session history for the browser instance. After the history has been cleared, calling **GoForward** will have no effect until new pages have been visited.

See Also

[CanGoBack Property](#), [CanGoForward Property](#), [GoBack Method](#), [Navigate Method](#), [HistoryChanged Event](#)

Initialize Method

Initialize the control and validate the runtime license key.

Syntax

object.Initialize([*LicenseKey*])

Parameters

LicenseKey

An optional string value which specifies a runtime license key used to initialize the control. If the license key is omitted or passed as an empty string, a development license must be installed on the local system.

Return Value

A value of zero is returned if the control was initialized successfully. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

This method dynamically loads other system libraries and allocates thread local storage. In most cases, it is not necessary to call this method directly because it is automatically invoked when an instance of the control is created by the container. However, if the control is created dynamically using **CreateObject** or a similar method, this must be the first method that is called before you attempt to modify any property values or invoke other methods. Failure to initialize the control may result in subsequent errors and/or cause an exception to be raised.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the control will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the control was created.

If the control is being used within another DLL, it is important that you do not attempt to create an instance of the control or call the **Initialize** method from within the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is written in C++ and it is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for any static and global C++ objects and has the same restrictions.

See Also

[IsInitialized Property](#), [Uninitialize Method](#)

Navigate Method

Description of the method.

Syntax

object.Navigate(Url)

Parameters

Url

A string which specifies the URL or local file to navigate to. Any leading and trailing whitespace will be removed and the URL will be normalized to ensure that it specifies a valid location. If the URL only specifies a domain name (such as "**example.com**") the browser will default to using a secure connection.

Return Value

Returns True if the method succeeds or False if the method fails.

Remarks

The **Navigate** method accepts both standard web URLs such as **https://www.example.com/** and local file paths which are automatically normalized and converted into **file://** URLs. This allows an application to load either remote web content or content from the local filesystem.

When a local file path is specified, the method validates the path to ensure that it refers to a valid, absolute file system location and is not under restricted system folders (such as the Windows or Program Files directories). Relative paths are resolved against the current working directory, but it is recommended that applications provide absolute paths to avoid ambiguity in multithreaded or service-hosted environments.

File names and paths are normalized before navigation. Illegal or reserved device names (such as **CON**, **AUX**, or **NUL**) and paths containing invalid characters will be rejected. UNC paths and extended-length paths using the **\\?** prefix are not supported. If the path points to a valid file, it will be loaded into the WebView using the appropriate **file://** URL form.

Note that navigation to local files is supported, but applications should exercise caution when mixing remote and local content, as this may have cross-origin security implications. If your application needs to load dynamic HTML content, consider setting the **DocumentText** property instead.

This method only supports navigation to standard web and local resources. Valid URL schemes are limited to **http://**, **https://**, **file://**, and **about:blank**. Other protocols or custom application schemes are not supported and will cause the method to fail. This includes the **edge://settings/profile** page or any other internal configuration settings for the Edge browser. If your application needs to handle such protocols, you should implement a custom handler to intercept those links and handle them externally.

See Also

[DocumentText Property](#), [Url Property](#), [NavigationCompleted Event](#), [NavigationStarting Event](#)

PostWebMessage Method

Sends a JSON-formatted message from the host application to scripts running inside the browser.

Syntax

object.PostWebMessage(*Message*)

Parameters

Message

A string which contains the message to be sent to the current page.

Return Value

Returns True if the method succeeds or False if the method fails.

Remarks

The **PostWebMessage** method sends a message from the host application to the currently loaded page using the WebView2 messaging channel. The call is asynchronous: if it is invoked from a thread other than the thread that created the browser instance, the method marshals the request to the UI thread and returns immediately, with delivery performed later on that thread. Internally, this posts a private window message to the host window; when handled, it forwards the text using the **ICoreWebView2::PostWebMessageAsString** method.

For a page to receive messages from the host, web messaging must be enabled. When the **AllowMessages** property is True, the wrapper enables web messages in the control settings (exposing **window.chrome.webview** to the script) and wires the corresponding message events. If this option is not enabled, the page will not see the messaging object and cannot receive messages.

On the JavaScript side, the page subscribes to messages using the standard listener pattern. Messages posted with this method are delivered as strings to the page's handler:

```
window.chrome.webview.addEventListener('message', (event) => {  
    // event.data is the string posted by WebViewPostWebMessage  
    const text = event.data;  
    // If you know the string is JSON, you can parse it explicitly  
    // const obj = JSON.parse(text);  
});
```

Because delivery is asynchronous, there is no built-in acknowledgement and ordering is not guaranteed across navigations. If the page navigates or reloads after you call **PostWebMessage**, a listener registered on the previous document will not receive later messages.

Messages are Unicode strings and you should avoid sending very large payloads. For large data transfers, consider using application-level protocols rather than embedding large content in a single message. This method is primarily intended to enable your host application to notify the web page the user has taken some action which should be reflected in the browser. The web page can send messages back to your application using **window.chrome.webview.postMessage(value)** and you can receive those messages using the **MessageReceived** event.

See Also

[AllowMessages Property](#), [MessageReceived Event](#)

PrintDocument Method

Displays a print dialog and allows the user to print the currently loaded document.

Syntax

object.PrintDocument

Parameters

None.

Return Value

Returns True if the method succeeds or False if the method fails.

Remarks

The **PrintDocument** method displays the print dialog for the currently loaded document. The dialog is shown asynchronously and the method will return once the print user interface has been invoked. This method does not perform the printing operation itself; it only initiates the print workflow and allows the user to select a printer, adjust preferences, and confirm printing.

This method can only be called after navigation has completed and the current document is fully loaded. If navigation is still in progress when the method is called, it will fail with an error indicating that the operation is in progress. This method only supports interactive printing through a user interface. If you need to programmatically export the document without user interaction, use the **SaveDocument** method instead.

See Also

[DocumentText Property](#), [SaveDocument Method](#)

Refresh Method

Reloads the current page, revalidating cached resources with the server if applicable.

Syntax

object.Refresh

Parameters

None.

Return Value

Returns True if the method succeeds or False if the method fails.

Remarks

The **Refresh** method reloads the current document and forces both the host window and the embedded WebView2 child window to repaint themselves. This differs from **Reload**, which simply reloads the page (similar to pressing **F5**) but does not explicitly invalidate and redraw the hosting window.

Internally, this method clears the browser cache and then forces a redraw by updating the control bounds and notifying the browser that the parent window has changed. If the host window itself is visible, it is also invalidated and updated to ensure that the client area is repainted.

Because this method performs multiple operations that can be relatively expensive, applications should generally prefer **Reload** unless a complete repaint of both the control and the host window is required. For example, it can be used if rendering artifacts are visible after a resize or when switching between different DPI contexts.

See Also

[Reload Method](#), [Reset Method](#)

Reload Method

Forces a complete reload of the current page.

Syntax

`object.Reload( ClearCache )`

Parameters

ClearCache

An optional boolean which indicates if the document cache for the session should be cleared. A value of True specifies the cache should be cleared; False specifies the cache should not be cleared. If this parameter is not specified, the cache will not be cleared.

Return Value

Returns True if the method succeeds or False if the method fails.

Remarks

The **Reload** method refreshes the currently loaded page, similar to pressing **F5** in a web browser. If the *ClearCache* parameter is True, the document cache is also cleared before reloading, ensuring that all resources are fetched again from the server instead of being served from the local cache.

This method is generally preferred over **Refresh** when an application only needs to reload the content without forcing the host window and browser control to repaint. It provides a lightweight way to refresh the page and optionally reset cached resources, without the overhead of a full redraw of the hosting window.

An application would typically use this method in response to a user action or when it needs to ensure the latest version of a document is displayed after cached data may have become stale.

See Also

[Refresh Method](#), [Reset Method](#)

Reset Method

Resets the browser instance by clearing its state and releasing cached document data.

Syntax

object.Reset

Parameters

None.

Return Value

None.

Remarks

The **Reset** method clears the state of the current browser session and restores it to its default configuration. This includes discarding cached content, navigation history, and any data associated with the last document. The control is then navigated to an empty **about:blank** page and the zoom level is reset to its default value.

Internally, this method releases cached strings such as the most recent message, script result, and document text, clears the current HTTP status and security information, removes cached data, and clears the session history. A navigation to **about:blank** is performed, and the host window is invalidated to ensure that the client area is repainted. The call blocks until the navigation has completed or the operation times out.

Because this method performs a complete reset of the WebView2 control, it should be used in situations where the browser needs to be returned to a known, clean state (for example, when reinitializing a session or preparing the control for a new task). Applications that only need to refresh the current document should use **Reload** or **Redraw** instead, as they are lighter-weight operations.

This method cannot be called while a navigation is already in progress. Attempting to do so will fail with an error code indicating that the operation is in progress. As with other navigation-related functions, it must be called on the thread that owns the browser window, or the request will be marshaled back to the UI thread.

See Also

[Cancel Method](#), [Initialize Method](#), [Uninitialize Method](#)

SaveDocument Method

Saves the currently displayed document in a specified format such as HTML, PDF, MHTML, or image.

Syntax

object.SaveDocument(*FileName*, [*FileType*])

Parameters

FileName

A string which specifies the name of the local file. If the path includes environment variables enclosed in percent (%) symbols, the variables will be expanded. This parameter must specify a valid file path. The file name cannot specify a device, folder name or system file. If the file is marked as read-only, the method will fail.

FileType

An optional parameter which specifies the file format. If this parameter is omitted, the format will be based on the file name extension.

Value	Value	Description
webSaveAsDefault	0	Save using a format inferred from the file extension. If the file extension is not recognized, the contents will be saved as plain text. For example, if you specify a file name with the .html extension, it will be saved in HTML format. If the file name has a .pdf extension, it will be saved as a PDF.
webSaveAsText	1	Saves the current document as plain text. The HTML tags are removed and entities are converted to their UTF-8 equivalent. Extraneous whitespace within the text will be removed, but the overall structure of ordered and unordered lists will be preserved. Choose this format if you wish to save only the text content of a document.
webSaveAsHtml	2	Saves the current document as a UTF-8 encoded HTML file. This includes the complete source for the page, but does not include any of the additional assets such as images. Choose this format if you wish to save the document as an editable HTML file.
webSaveAsJson	3	Saves the current document as a JSON formatted string. The string will be quoted and reserved characters will be escaped. Choose this format if you wish to preserve the HTML document as a JSON string for logging or embedding in a JSON object.
webSaveAsMhtml	4	Saves the current document as a single-file web archive (MHTML) that inlines the HTML content and all of the resources it references. This format calls the DevTools Page.captureSnapshot method in the browser and writes the returned data to disk. MHTML is useful for offline archiving since it combines images, styles and scripts together in a single file.

webSaveAsPdf	5	Saves the current document as a PDF file which produces a paginated document suitable for printing and distribution. This is functionally similar to using the browser to print to a PDF, but does not display a dialog to the user.
webSaveAsJpeg	101	Save the current document view as a JPEG image. JPEG is a widely used image format optimized for photographs and complex images with smooth gradients. It uses lossy compression to significantly reduce file size while maintaining acceptable visual quality.
webSaveAsPng	102	Save the current document view as a PNG image. PNG is a lossless image format designed for crisp detail and high fidelity, especially in graphics with sharp edges, text, or flat colors. Although PNG files are typically larger than JPEGs, they preserve exact image data without quality loss.
webSaveAsWebP	103	Save the current document view as a WebP image. WebP is a modern image format developed by Google that supports both lossy and lossless compression, as well as transparency and animation. It delivers smaller file sizes compared to JPEG and PNG while maintaining comparable or better visual quality.

Return Value

Returns True if the method succeeds or False if the method fails.

Remarks

The **SaveDocument** method saves the current page to a local file in the format specified by the **FileType** parameter. The operation is synchronous, processing messages while the browser completes the action, and only returns once the document has been created or the operation has failed. A temporary file is created during the save process and then moved into place, replacing any existing file. This ensures that an existing file will not be changed unless the browser indicates the save operation was successful. Saving is not permitted while a navigation is in progress, and attempts to do so will fail with an error.

The file name specified must be valid, and environment variables in the path are expanded before use. When no file type is specified, the format is inferred from the file extension. For example, **.html** or **.htm** will save the document as HTML, **.pdf** will create a PDF file and **.png** will save the page as a PNG image. If no recognized extension is present, the page will be saved as plain text by default.

When saving the current document as plain text, the HTML markup will be removed and it will be saved as a UTF-8 encoded text file. When saving as HTML, the method saves the complete HTML source for the page. The JSON format also saves the HTML markup, but encodes it as a quoted JSON string with reserved characters escaped. Note that all text-related formats are saved using UTF-8 multi-byte encoding without a byte order mark (BOM). The text will not be automatically converted to the current user's locale. Most modern text editors automatically recognize UTF-8 encoding, but some legacy applications may assume the text is localized to the current code page.

The MHTML option creates a single-file archive which contains the page content and all of its resources such as images, style sheets, and scripts. This format is often used for offline archiving or sharing since everything is contained in one file. Saving as PDF renders the page into a paginated print-style format suitable for distribution. These formats all operate on the complete document,

including content that extends beyond the visible area.

By contrast, saving as an image (JPEG, PNG, or WebP) captures only the visible viewport of the page at the time the method is called. Content that requires scrolling will not be included in the saved image. PNG is lossless and preserves transparency, while JPEG and WebP use compression to produce smaller files. WEBP generally offers better quality at a reduced size compared to JPEG, but support for the format may vary between applications. If you want a pixel-perfect representation of the current page as it appears on the screen, particularly if it contains a lot of text, it is recommended that you use the PNG format.

Because this method blocks the current thread until the save completes, it may take a noticeable amount of time to return if the current document is very large. If the method is called from a worker thread, the request is marshaled to the UI thread that manages the browser control. For applications with a graphical interface, it is recommended that you display the standard hourglass (or other busy indicator) while the save is in progress to provide a visual cue to the user.

If you want a copy of the HTML or plain text contents of the current page without saving it to a file, use the **DocumentText** or **FilteredText** properties.

See Also

[DocumentText Property](#), [FilteredText Property](#), [PrintDocument Method](#)

SetHeader Method

Set the value of a request header field.

Syntax

object.SetHeader HeaderField, HeaderValue

Parameters

HeaderField

A string that specifies the name of the request header field.

HeaderValue

A string that specifies the value associated with the given header field. If this argument is set to an empty string, the field is deleted from the request header.

Return Value

This method returns a boolean value. If the method succeeds, it will return **True**. If the header field cannot be created or modified, it will return **False**.

Remarks

The **SetHeader** method adds or updates a custom request header that will be included with subsequent navigations. Request header names are not case-sensitive, and any leading or trailing whitespace is ignored. If the specified header value is **NULL** or an empty string, the header will be removed from the current list of custom headers. These changes only affect future requests; they do not modify headers already sent for the current navigation.

Certain standard headers are controlled by the underlying **WebView2** control and may be ignored if set programmatically. Examples include **Host**, **Referer**, **Origin**, **User-Agent**, and most authentication headers. Attempting to override these may have no effect. For headers that can be set, the specified values will be merged with the default request headers used by **WebView2** when making requests. If you wish to change the **User-Agent** header value, set the **UserAgent** property.

When defining custom request headers, it is recommended to use names prefixed with **X-** (for example, **X-Application-ID** or **X-Request-Token**). This convention helps distinguish application-specific headers from those defined by the HTTP standard, and reduces the likelihood of conflicts with headers that are managed internally by **WebView2** or intermediaries such as proxies and gateways. While most modern systems will accept arbitrary header names, following this convention improves compatibility and avoids unexpected behavior.

If you need to clear all custom request headers that have been set, call the **ClearHeaders** method.

See Also

[ClearHeaders Method](#), [GetFirstHeader Method](#), [GetHeader Method](#), [GetNextHeader Method](#),

Uninitialize Method

Uninitialize the control and release any system resources that were allocated.

Syntax

object.Uninitialize

Parameters

None.

Return Value

None.

Remarks

The **Uninitialize** method terminates any connection established by the control and resets the internal state of the control. This method is not typically used because any resources that have been allocated by an instance of the control will automatically be released when it is destroyed.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the control will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the control was created. An application should only call the **Uninitialize** method if it has explicitly called the **Initialize** method.

See Also

[Initialize Method](#)

ZoomIn Method

Increases the zoom level for the current document.

Syntax

object.ZoomIn

Parameters

None.

Return Value

Returns True if the method succeeds or False if the method fails.

Remarks

The **ZoomIn** method increases the zoom level for the current document.

Changing the zoom level affects how the page content is displayed but does not alter the underlying document. This is equivalent to adjusting the zoom in a standard web browser. The new zoom level applies to the current browser instance and will remain in effect until it is changed again, or the control is destroyed.

The value of the **AllowZoom** property does not affect your ability to change the zoom level using this method. The **ZoomLevel** property can be used to set the view to a specific percentage value.

See Also

[AllowZoom Property](#), [ZoomLevel Property](#), [ZoomOut Method](#)

ZoomOut Method

Decreases the zoom level for the current document.

Syntax

object.ZoomIn

Parameters

None.

Return Value

Returns True if the method succeeds or False if the method fails.

Remarks

The **ZoomOut** method decreases the zoom level for the current document.

Changing the zoom level affects how the page content is displayed but does not alter the underlying document. This is equivalent to adjusting the zoom in a standard web browser. The new zoom level applies to the current browser instance and will remain in effect until it is changed again, or the control is destroyed.

The value of the **AllowZoom** property does not affect your ability to change the zoom level using this method. The **ZoomLevel** property can be used to set the view to a specific percentage value.

See Also

[AllowZoom Property](#), [ZoomLevel Property](#), [ZoomIn Method](#)

WebView Events

Event	Description
AcceleratorKeyPress	This event occurs when an accelerator key is pressed while the browser has focus.
DownloadCompleted	This event occurs when a file download has completed.
DownloadStarting	This event occurs when a file download is starting, allowing the application to cancel the download if needed.
HistoryChanged	This event occurs when the navigation history state changes, such as when navigating to a new page.
Initialize	This event occurs after the control has been created by the form, prior to the browser environment being initialized.
MessageReceived	This event occurs when a script running inside the browser sends a message to the host.
NavigationCompleted	This event occurs when a navigation finishes loading and indicates whether it was successful or not.
NavigationStarting	This event occurs before a new navigation begins, allowing the application to cancel the navigation if needed.
Resize	This event occurs when the control is resized, typically in response to the host window being resized.
ScriptCompleted	This event occurs when an asynchronous script execution completes.
SecurityChanged	This event occurs when the security state of the current page changes.

AcceleratorKeyPress Event

The **AcceleratorKeyPress** event occurs when an accelerator key is pressed while the browser has focus.

Syntax

Sub *object_AcceleratorKeyPress* ([*Index As Integer*,] **ByVal** *KeyCode As Integer*, *Handled As Boolean*)

Remarks

This event is raised when the user presses an accelerator key combination such as the arrow keys, Page Up and Page Down, Insert, Delete, or other keys that the embedded browser normally handles. The **KeyCode** value is the virtual key code. The event gives your application a chance to intercept these keystrokes before they are processed by the browser. This is especially useful when you want to provide custom navigation, prevent certain keys from being used, or integrate the control with application-level keyboard shortcuts. To prevent the default behavior being taken by the browser, set the **Handled** parameter to True from within this event.

See Also

[ContextMenu Property](#), [Enabled Property](#)

DownloadCompleted Event

The **DownloadCompleted** event occurs when a file download has completed.

Syntax

```
Sub object_DownloadCompleted ( [Index As Integer,] ByVal FileName As String, ByVal FileSize As Double, ByVal Status As Long )
```

Remarks

This event occurs when a file download has completed. The **FileName** argument specifies the full path to the file that was downloaded and the **FileSize** agument specifies the size of the file in bytes.

The **Status** argument indicates the status of the download and may be one of the following values:

Constant	Value	Description
webDownloadStarted	1	The file download has started and is in-progress.
webDownloadCompleted	2	The file download has completed successfully.
webDownloadCanceled	3	The file download has been canceled.
webDownloadFailed	4	The file download failed due to a network error or other problem.

See Also

[DownloadStarting Event](#)

DownloadStarting Event

The **DownloadStarting** event occurs when a file download is starting, allowing the application to cancel the download if needed.

Syntax

Sub *object_DownloadStarting* ([*Index As Integer*,] **ByVal** *FileUrl As String*, *FileName As String*, *Cancel As Boolean*)

Remarks

This event occurs when a file download is initiated either by a user clicking on a link or navigating to a URL which specifies content that cannot be rendered in the browser and the **FileUrl** argument specifies the URL for the file being downloaded, the **FileName** argument is the path to the local file that will be created. The local file name is passed by reference to the event and can be changed in the event to specify a different file path and/or name if needed.

To prevent the file from being downloaded, set the **Cancel** argument to True inside the event handler. If the download is canceled, the browser will not show the normal progress dialog in the upper-right corner of the control window.

See Also

[DownloadCompleted Event](#)

HistoryChanged Event

The **HistoryChanged** event occurs when the navigation history state changes, such as when navigating to a new page.

Syntax

Sub *object_HistoryChanged*([*Index As Integer*])

Remarks

The **HistoryChanged** event occurs whenever the browsing history changes and the value of the **CanGoBack** and **CanGoForward** properties will be updated. Navigating to a new page, using the **GoBack** or **GoForward** methods, or programmatically calling navigation functions can trigger this event. Your application can respond by enabling or disabling UI elements such as toolbar buttons depending on whether it is possible to go back or forward.

See Also

[CanGoBack Property](#), [CanGoForward Property](#), [GoBack Method](#), [GoForward Method](#), [Navigate Method](#)

Initialize Event

The **Initialize** event occurs after the control has been created by the form, prior to the browser environment being initialized.

Syntax

Sub *object_Initialize* ([*Index As Integer*])

Remarks

This event occurs immediately after the form has created an instance of the control, but prior to the WebView2 browser being attached to the control window. This allows your application to set certain properties, such as the **DataFolder** and **InPrivate** properties, which cannot be changed after a browser environment has been created. In most cases, it's simpler to set these property values in design mode using the property browser; however, if you need to initialize these properties programatically, it must be done within this event.

See Also

[DataFolder Property](#), [InPrivate Property](#), [Initialize Method](#)

MessageReceived Event

The **MessageReceived** event occurs when a script running inside the browser sends a message to the host.

Syntax

Sub *object_MessageReceived* ([*Index As Integer*,] **ByVal** *Message As String*)

Remarks

The **MessageReceived** event occurs when a message is posted from JavaScript code in the web page using **window.chrome.webview.postMessage**. The message is delivered as a string, which can be accessed using the *Message* argument. The message may be structured JSON data, or it may be a simple JSON formatted string. This event provides a two-way communication channel between the page content and the host application, allowing developers to implement hybrid scenarios where the web page can notify the native host of user actions, requests, or state changes.

If the **AllowMessages** property is set to **False**, this event will not be raised.

See Also

[AllowMessages Property](#), [PostWebMessage Method](#)

NavigationCompleted Event

The **NavigationCompleted** event occurs when a navigation finishes loading and indicates whether it was successful or not.

Syntax

Sub *object_NavigationCompleted* ([*Index As Integer*,] **ByVal** *Location As String*, **ByVal** *ErrorCode As Long*)

Remarks

The **NavigationCompleted** event occurs when a navigation request has finished loading. It is triggered regardless of whether the navigation succeeded or failed, with the *Location* argument being the URL and the *ErrorCode* argument indicating any failure. Applications typically handle this event to update their UI once the content has loaded, or to implement custom error handling when navigation fails. Because the event always fires, even on errors, it is a reliable notification point for the end of a navigation sequence.

If the navigation has failed, **ErrorCode** will be non-zero and can be one of the following values:

Constant	Value	Description
webErrorCertificateName	1	Certificate common name mismatch.
webErrorCertificateExpired	2	Certificate is expired.
webErrorInvalidCredentials	3	Invalid or untrusted client certificate.
webErrorCertificateRevoked	4	Certificate has been revoked.
webErrorInvalidCertificate	5	Certificate is invalid for another reason.
webErrorServerUnreachable	6	Cannot reach the server/host.
webErrorTimeout	7	Operation timed out.
webErrorInvalidServerResponse	8	Server returned an invalid or unexpected response.
webErrorConnectionAborted	9	Connection aborted by the server or network.
webErrorConnectionReset	10	Connection was reset.
webErrorDisconnected	11	Disconnected during the operation.
webErrorCannotConnect	12	Failed to establish a connection.
webErrorHostNameNotResolved	13	DNS resolution failed for the host.
webErrorOperationCanceled	14	Operation was canceled by the user or host.
webErrorRedirectFailed	15	Redirection failed.
webErrorUnexpectedError	16	An unexpected error occurred.
webErrorCredentialsRequired	17	Authentication credentials are required.
webErrorProxyAuthRequired	18	Proxy authentication is required.

See Also

[Navigate Method](#), [NavigationStarting Event](#)

DownloadStarting Event

The **DownloadStarting** event occurs before a new navigation begins, allowing the application to cancel the navigation if needed.

Syntax

Sub *object_DownloadStarting* ([*Index As Integer*,] **ByVal** *Location As String*, *Cancel As Boolean*)

Remarks

The **DownloadStarting** event is fired when a new navigation request begins. The event is raised before any network request is made, ensuring that no data is sent until the handler has had a chance to approve or deny the navigation. The ***Location*** argument specifies the URL for the new location and setting the ***Cancel*** argument to True will cancel the navigation before it can begin.

See Also

[Navigate Method](#), [NavigationCompleted Event](#)

Resize Event

The **Resize** event occurs when the control is resized, typically in response to the host window being resized.

Syntax

Sub *object_Resize* ([*Index As Integer*])

Remarks

The Resize event occurs whenever the browser window is resized. The control's **Width** and **Height** property values will contain the new dimensions.

See Also

[Focused Property](#)

ScriptCompleted Event

The **ScriptCompleted** event occurs when an asynchronous script execution completes.

Syntax

Sub *object_ScriptCompleted* ([*Index As Integer*,] **ByVal** *Response As String*, **ByVal** *StatusCode As Long*)

Remarks

The **ScriptCompleted** event is raised when a script execution initiated by the application completes. The **Response** argument specifies the string returned by the script, and the **StatusCode** value indicates success (1) or failure (0). If the script contained errors or could not be executed, the status code will be zero. Applications typically use this event to retrieve values from the page, execute custom logic in response to script results, or detect when asynchronous script operations have finished. Because script execution is asynchronous, this event is the definitive way to know when a script call has finished.

See Also

[AsyncExecute Method](#), [PostWebMessage Method](#)

SecurityChanged Event

The **SecurityChanged** event occurs when the security state of the current page changes.

Syntax

Sub *object_SecurityChanged* ([*Index As Integer*,] *ByVal Level As Long*)

Remarks

The **SecurityChanged** event is raised when the security level of the current connection changes, with the **Level** argument indicating the security level. For example, the level may change from neutral to secure once a certificate has been validated, or from secure to warning if mixed content is detected. Additional information about the state of the connection can be obtained by checking the value of the **Certificate** and **Encryption** properties which are updated when this event occurs.

Applications often use this event to update visual indicators such as a padlock icon or to apply additional security-related policies. It is important to note that this event may be raised multiple times during a single navigation, and earlier values should be discarded in favor of the most recent state.

The **Level** argument may be one of the following values:

Constant	Value	Description
webSecurityLevelUnknown	0	The security state could not be determined.
webSecurityLevelInsecure	1	The page was retrieved using plain HTTP or the site has an invalid certificate.
webSecurityLevelWarning	2	The page contains mixed content or only weak encryption is available.
webSecurityLevelNeutral	3	Local content or the browser is in a transitional/loading state.
webSecurityLevelSecure	4	The page was retrieved using HTTPS and the site has a valid certificate.

Whois Protocol Control

Request registration information for an Internet domain name.

Reference

- [Properties](#)
- [Methods](#)
- [Events](#)
- [Error Codes](#)

Control Information

Object Name	WhoisClientCtl.WhoisClient
File Name	CSWHOX12.OCX
Version	12.0.3024.1286
ProgID	SocketTools.WhoisClient.12
ClassID	85F0824A-ED41-4ECA-AB52-F7A4A57023F1
Threading Model	Apartment
Help File	CST12CTL.CHM
Dependencies	None
Standards	RFC 954

Overview

The Whois protocol control provides an interface for requesting registration information for an Internet domain name. When a domain name is registered, the organization that registers the domain must provide certain contact information along with technical information such as the primary name servers for that domain. The control provides an interface for requesting that information and returning it to the program so that it can be displayed or processed. This control would be most commonly used to query the Whois server at **whois.internic.net** to obtain information about a specific Internet domain name or an administrative contact at that domain.

Requirements

The SocketTools ActiveX Edition components are self-registering controls that are compatible with any programming language that supports the Component Object Model (COM) and the ActiveX control specification. If you are using Visual Basic 6.0, Service Pack 6 (SP6) is required. We recommend installing all available updates for your development tools. Although the Visual Basic 6.0 runtime is supported on Windows 11, the IDE itself is no longer officially supported by Microsoft. Legacy IDEs and compilers may also require elevated (administrator) privileges to run properly.

The ActiveX controls are supported on Windows 7, Windows Server 2008 R2, and later versions of both desktop and server editions of Windows. For Windows 7, Service Pack 1 (SP1) is the minimum requirement. For Windows 8 systems, the 8.1 update must be installed. On ARM-based platforms, the minimum supported version is Windows 10 build 1709.

SocketTools includes components for both 32-bit (x86) and 64-bit (x64) Windows platforms. All modern versions of Windows are 64-bit, but we continue to include 32-bit components for

compatibility with legacy development tools such as Visual Basic 6.0. We also provide native ARM64 ActiveX controls for systems running Windows on ARM. Note that 32-bit applications on ARM run using x86 emulation, and Microsoft no longer supports native ARM32 applications.

If you are using VBScript, Visual Basic for Applications (VBA), or another scripting environment on an ARM-based system, be aware that 64-bit hosts will require ARM64 components, while 32-bit hosts will use x86 components under emulation. This includes applications created with Visual Basic 6.0. To reduce deployment complexity and avoid confusion, SocketTools does not include ARM32 ActiveX controls in its standard redistribution packages but they are available on request for legacy or specialized scenarios.

Distribution

When you distribute an application that uses this control, you can either install the file in the same folder as your application executable or as a shared component in the appropriate system folder. If you install the control in the system folder, it is important that you distribute the correct version for the target platform and it must be registered. If you install the control in the same folder as your executable, it is recommended that you use registration-free activation or COM redirection to ensure that the correct version of the control is loaded by the application.

Whois Protocol Control Properties

Property	Description
AutoResolve	Determines if host names and IP addresses are automatically resolved
Blocking	Gets and sets the blocking state of the control
HostAddress	Gets and sets the IP address of the server
HostName	Gets and sets the name of the server
IsBlocked	Return if the control is blocked performing an operation
IsConnected	Determine if the control is connected to a server
IsInitialized	Determine if the control has been initialized
IsReadable	Return if data can be read from the server without blocking
Keyword	Specify the keyword to search for
LastError	Gets and sets the last error that occurred on the control
LastErrorString	Return a description of the last error to occur
RemotePort	Gets and sets the port number for a remote connection
SearchType	Specify the type of query to be performed by the server
ThrowError	Enables or disables error handling by the application
Timeout	Gets and sets the amount of time until a blocking operation fails
Trace	Enable or disable socket function level tracing
TraceFile	Specify the socket function trace output file
TraceFlags	Gets and sets the socket function tracing flags
Version	Return the current version of the control

AutoResolve Property

Determines if host names and IP addresses are automatically resolved.

Syntax

object.AutoResolve [= { True | False }]

Remarks

Setting the **AutoResolve** property determines if the control automatically resolves host names and addresses specified by the **HostName** and **HostAddress** properties. If set to True, setting the **HostName** property will cause the control to automatically determine the corresponding IP address and set the **HostAddress** property accordingly. Likewise, setting the **HostAddress** property will cause the control to determine the host name and set the **HostName** property. Setting the property to False prevents the control from resolving host names until a connection attempt is made.

Note that setting the **HostName** or **HostAddress** property may cause the current thread to block, sometimes for several seconds, until the name or address is resolved. To prevent this behavior, set **AutoResolve** to False.

Data Type

Boolean

See Also

[HostAddress Property](#), [HostName Property](#)

Blocking Property

Gets and sets the blocking state of the control.

Syntax

object.**Blocking** [= { True | False }]

Remarks

Setting the **Blocking** property determines if control actions complete synchronously or asynchronously. If set to True, then each control action, such as sending or receiving data, will return when the operation has completed or timed-out. If set to False, control actions will return immediately. If the operation would result in the control blocking, such as attempting to read data when none has been written, an error is generated. Events such as **OnConnect**, **OnDisconnect**, **OnRead** and **OnWrite** are only fired if the connection is non-blocking.

Data Type

Boolean

See Also

[IsBlocked Property](#), [IsReadable Property](#)

HostAddress Property

Gets and sets the IP address of the server.

Syntax

object.HostAddress [= *ipaddress*]

Remarks

The **HostAddress** property can be used to set the IP address for a server that you wish to communicate with. If the address is valid and matches an entry in the host table, the **HostName** property will be changed to match the address.

Data Type

String

See Also

[AutoResolve Property](#), [HostName Property](#)

HostName Property

Gets and sets the name of the server.

Syntax

object.HostName [= *hostname*]

Remarks

The **HostName** property should be set to the name of the server that you wish to communicate with. If the name is found in the host table, the **HostAddress** property is updated to reflect the IP address of the host.

Note that it is legal to assign an IP address to this property, but it is not legal to assign a host name to the **HostAddress** property.

Data Type

String

See Also

[AutoResolve Property](#), [HostAddress Property](#)

IsBlocked Property

Return if the control is blocked performing an operation.

Syntax

object.IsBlocked

Remarks

The **IsBlocked** property returns True if the specified control is blocked performing an operation. Because the Windows Sockets API only permits one blocking operation per thread of execution, this property should be checked before starting any blocking operation.

Note that this property will return True if there is *any* blocking operation being performed by the application, regardless if the specified control is responsible for the blocking operation or not.

Data Type

Boolean

See Also

[Blocking Property](#), [LastError Property](#)

IsConnected Property

Determine if the control is connected to a server.

Syntax

object.**IsConnected**

Remarks

The **IsConnected** read-only property is set to a value of true if the control is connected with a server, otherwise the property has a value of false.

Data Type

Boolean

IsInitialized Property

Determine if the control has been initialized.

Syntax

object.IsInitialized

Remarks

The **IsInitialized** property is used to determine if the current instance of the control has been initialized properly. Normally this is done automatically when the control is loaded, however there are circumstances where the control may not be able to initialize itself. If this property returns **False**, the application must call the **Initialize** method to initialize the control before performing any other operation.

The most common reason that the control may not initialize correctly is that no valid development or runtime license key can be found or the license key that was provided is invalid. It may also indicate a problem with the system configuration or user access rights, such as not being able to load the required networking libraries or not being able to access the system registry.

Data Type

Boolean

See Also

[Initialize Method](#)

IsReadable Property

Return if data can be read from the server without blocking.

Syntax

object.IsReadable

Remarks

The **IsReadable** property returns True if data can be read from the server without blocking. For non-blocking connections, this property can be checked before the application attempts to read the data, preventing an error.

Data Type

Boolean

See Also

[IsConnected Property](#), [Read Method](#), [OnRead Event](#)

Keyword Property

Specify the keyword to search for.

Syntax

object.Keyword [= *value*]

Remarks

The **Keyword** property specifies the value used when querying the server. The keyword may refer to a handle, a user name or a mailbox name. Setting this property provides the default keyword for the **Search** method.

Keywords may contain special characters that instruct the server how to match the value. These values are outlined in RFC 954, the standards document that describes the WHOIS/NICNAME protocol. These forms are typically recognized:

Example	Description
value	Search for value as either a user name or a handle
value...	Search for value that matches anything up to that point
!value	Search for a handle that matches the given value
last, first	Search for the specified name
user@	Search for mailboxes with the given user name
@host	Search for mailboxes on the specified host
user@host	Search for mailboxes for the user on the specified host

If the keyword uses any of these special forms, the **SearchType** property must be set to **whoisSearchAny**, which tells the control not to modify the keyword value when submitting the query to the server. Note that all keyword forms may not be supported by a given server, and additional types of searches may be supported.

Data Type

String

See Also

[SearchType Property](#), [Connect Method](#), [Search Method](#)

LastError Property

Gets and sets the last error that occurred on the control.

Syntax

object.LastError [= *value*]

Remarks

The **LastError** property can be read to determine the last error that occurred for this control. If a value is assigned to this property, it must either be zero to clear the error or a valid error code for the control.

Data Type

Integer (Int32)

See Also

[LastErrorString Property](#), [OnError Event](#)

LastErrorString Property

Return a description of the last error to occur.

Syntax

object.LastErrorString

Remarks

The **LastErrorString** property returns a description of the last error that occurred. This can be used to display a meaningful error message to a user, rather than just the numeric value returned by the **LastError** property.

Data Type

String

See Also

[LastError Property](#), [OnError Event](#)

RemotePort Property

Gets and sets the port number for a remote connection.

Syntax

object.RemotePort [= *portnumber*]

Remarks

The **RemotePort** property is used to set the port number that the control will use to establish a connection with the server.

Data Type

Integer (Int32)

See Also

[HostAddress Property](#), [HostName Property](#)

SearchType Property

Specify the type of query to be performed by the server.

Syntax

`object.SearchType [= value ]`

Remarks

The **SearchType** property specifies the default type of query to be performed by the server using the **Search** method. The following table lists the types of searches that may be performed:

Value	Constant	Description
whoisSearchAny	Search for any value that matches the given keyword value	
whoisSearchHandle	Search for a handle that matches the given keyword value	
whoisSearchName	Search for a user name that matches the given keyword value	
whoisSearchMailbox	Search for a user mailbox that matches the given keyword value	

If you wish to perform a more complex query using the syntax outlined in RFC 954, specify a search type of **whoisSearchAny** and then provide the search string value that you want to submit.

Data Type

Integer (Int32)

See Also

[Keyword Property](#), [Connect Method](#), [Search Method](#)

ThrowError Property

Enables or disables error handling by the application.

Syntax

object.ThrowError = { True | False }

Remarks

Error handling for methods can be performed using either return codes or exceptions, depending on the value of this property.

If the **ThrowError** property is set to False, methods will return a status value indicating success or failure. Applications should check the return value of each method and use the **LastError** and **LastErrorString** properties to determine the cause of any error.

If the **ThrowError** property is set to True, errors occurring within the control will be raised to the host application as ActiveX exceptions. In addition, the **OnError** event will fire. This allows applications to use language-specific exception handling mechanisms, such as Visual Basic error handling, instead of checking individual return values after each method call.

Even when the **ThrowError** property is set to True, the **LastError** and **LastErrorString** properties will still be updated with information about the most recent error.

If an error occurs while accessing a property value, an exception will be raised regardless of the value of the **ThrowError** property. However, the **OnError** event will not be fired for property access errors.

Data Type

Boolean

Example

The following example handles errors by checking the return code of a method:

```
WhoisClient1.ThrowError = False
nError = WhoisClient1.Connect(strHostName)

If nError > 0 Then
    MsgBox WhoisClient1.LastErrorString, vbExclamation
    Exit Sub
End If
```

The following example handles errors by throwing them to the container:

```
On Error Resume Next: Err.Clear

WhoisClient1.ThrowError = True
WhoisClient1.Connect strHostName

If Err.Number <> 0
    MsgBox Err.Description, vbExclamation
    Exit Sub
End If
On Error GoTo 0
```

See Also

[LastError Property](#), [LastErrorString Property](#), [OnError Event](#)

Timeout Property

Gets and sets the amount of time until a blocking operation fails.

Syntax

object.**Timeout** [= *seconds*]

Remarks

Setting the **Timeout** property specifies the number of seconds until a blocking operation fails and the control returns an error.

Note that the **Timeout** property also determines the amount of time the control will spend attempting to connect to a server. If a connection is not established within the given time period, the connection attempt will fail.

Data Type

Integer (Int32)

Trace Property

Enable or disable network function level logging.

Syntax

`object.Trace` [= { True | False }]

Remarks

The **Trace** property is used to enable or disable the logging of network function calls. When enabled, each function call is logged to a file, including the function parameters, return value and error code if applicable. This facility can be enabled and disabled at run time, and the trace log file can be specified by setting the **TraceFile** property. All function calls that are being logged are appended to the trace file, if it exists. If no log file exists when tracing is enabled, the file is created.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

Data Type

Boolean

See Also

[TraceFile Property](#), [TraceFlags Property](#)

TraceFile Property

Gets and sets the name of the file to use when logging network function calls.

Syntax

`object.TraceFile [= filename ]`

Remarks

The **TraceFile** property is used to specify the name of the file that is created when logging is enabled. If this property is set to an empty string (the default value), then a file named **SocketTools.log** is created in the current user's Documents folder. It is recommended that you always specify a complete path to the log file. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

If the file exists, the output is appended to the file, otherwise the file is created. Since logging is enabled per-process, the log file is shared by all instances of the controls being used. If you create multiple instances of the control, you only need to enable logging for a single instance. Because log files can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "0x". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxx:xxxx:xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, the control is attempting to connect to a system with the IPv4 address 192.0.0.1 on port 1234.

If the log file cannot be created, or the user does not have permission to modify an existing file, the error is silently ignored and no output will be generated.

Data Type

String

See Also

TraceFlags Property

Gets and sets the network function logging flags.

Syntax

`object.TraceFlags [= flags ]`

Remarks

The **TraceFlags** property is used to specify the type of information written to the trace file when socket function tracing is enabled. The following values may be used:

Value	Description
dnsTraceInfo	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
dnsTraceError	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
dnsTraceWarning	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
dnsTraceHexDump	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
dnsTraceTruncate	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.

Since logging is enabled per-process, the trace flags are shared by all instances of the control being used. If multiple controls have tracing enabled, the **TraceFlags** property should be set to the same value for each control. Changing the trace flags for any one instance of the control will affect the logging performed for all other instances used by the application.

Warnings are generated when a non-fatal error is returned by a Windows Sockets function. For example, if data is being written through the control and an error indicating that the operation would block is returned, only a warning is logged since the application simply needs to attempt to write the data at a later time.

Data Type

Integer (Int32)

Version Property

Return the current version of the control.

Syntax

object.Version

Remarks

The **Version** property returns the current version of the object. This can be used by an application for validation purposes. The version returned is composed of four numbers, separated by periods. The first number is the major version number, the second number is the minor version number, the third is the build number and the fourth is the revision number.

Data Type

String

Whois Protocol Control Methods

Method	Description
Cancel	Cancels the current blocking network operation
Connect	Establish a connection with a server
Disconnect	Terminate the connection with a server
Initialize	Initialize the control and validate the runtime license key
Read	Return data read from the server
Reset	Reset the internal state of the control
Search	Search for the specified record
Uninitialize	Uninitialize the control and release any system resources that were allocated

Cancel Method

Cancels the current blocking network operation.

Syntax

object.Cancel

Parameters

None.

Return Value

None.

Remarks

The **Cancel** method cancels any blocking network operation in the current thread. This is typically used inside an event handler, causing the blocking method to return to the caller with an error indicating that the current operation was canceled. This method sets an internal flag that is periodically checked during a blocking operation, such as waiting for more data to arrive. If the current thread is not blocked at the time that this method is called, it will have no effect.

See Also

[Disconnect Method](#), [Reset Method](#), [OnCancel Event](#)

Connect Method

Establish a connection with a server.

Syntax

object.Connect([RemoteHost], [RemotePort], [Timeout], [Options])

Parameters

RemoteHost

A string which specifies the host name or IP address of the server. If this argument is not specified, it defaults to the value of the **HostAddress** property if it is defined. Otherwise, it defaults to the value of the **HostName** property.

RemotePort

A number which specifies the port to connect to on the server. If this argument is not specified, it defaults to the value of the **RemotePort** property. A value of zero indicates that the default port number for this service should be used to establish the connection.

Timeout

The number of seconds that the client will wait for a response before failing the operation. If this argument is not specified, the value of the **Timeout** property will be used as the default.

Options

A reserved parameter. This argument should either be omitted, or always be zero.

Return Value

A value of zero is returned if the connection was successful. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

See Also

[HostAddress Property](#), [HostName Property](#), [RemotePort Property](#), [Disconnect Method](#), [OnConnect Event](#)

Disconnect Method

Terminate the connection with a server.

Syntax

object.Disconnect

Parameters

None.

Return Value

A value of zero is returned if the connection was terminated successfully. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

This method terminates the network connection with the server.

See Also

[IsConnected Property](#), [Connect Method](#), [OnDisconnect Event](#)

Initialize Method

Initialize the control and validate the runtime license key.

Syntax

```
object.Initialize( [LicenseKey] )
```

Parameters

LicenseKey

An optional string value which specifies a runtime license key used to initialize the control. If the license key is omitted or passed as an empty string, a development license must be installed on the local system.

Return Value

A value of zero is returned if the control was initialized successfully. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

This method dynamically loads other system libraries and allocates thread local storage. In most cases, it is not necessary to call this method directly because it is automatically invoked when an instance of the control is created by the container. However, if the control is created dynamically using **CreateObject** or a similar method, this must be the first method that is called before you attempt to modify any property values or invoke other methods. Failure to initialize the control may result in subsequent errors and/or cause an exception to be raised.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the control will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the control was created.

If the control is being used within another DLL, it is important that you do not attempt to create an instance of the control or call the **Initialize** method from within the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is written in C++ and it is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for any static and global C++ objects and has the same restrictions.

Example

```
Set whoisClient = CreateObject("SocketTools.WhoisClient.12")

nError = whoisClient.Initialize(strLicenseKey)
If nError > 0 Then
    MsgBox "Unable to initialize SocketTools component"
End
End If
```

[IsInitialized Property](#), [Uninitialize Method](#)

Read Method

Return data read from the server.

Syntax

object.Read(*Buffer*, [*Length*])

Parameters

Buffer

A buffer that the data will be stored in. If the variable is a **String** then the data will be returned as a string of characters. If the data returned by the server contains UTF-8 encoded text, it will automatically be converted to standard UTF-16 Unicode text. If you wish to read the data without conversion, provide a **Byte** array as the buffer. This parameter must be passed by reference.

Length

A numeric value which specifies the number of bytes to read. Its maximum value is $2^{31}-1 = 2147483647$. This argument is required to be present for string data. If a value is specified for this argument for other permissible types of data, and it is less than number of bytes that is determined by the control, then **Length** will override the internally computed value. If the argument is omitted, then the maximum number of bytes to read is determined by the size of the buffer.

Return Value

The number of bytes actually read from the server is returned by this method. If an error occurs, a value of -1 is returned.

Remarks

The **Read** method returns data that has been read from the server, up to the number of bytes specified. If no data is available to be read, an error will be generated if the control is non-blocking mode. If the control is in blocking mode, the program will wait until data is returned by the server or the connection is closed.

See Also

[IsConnected Property](#), [IsReadable Property](#), [OnRead Event](#)

Reset Method

Reset the internal state of the control.

Syntax

object.Reset

Parameters

None.

Return Value

None.

Remarks

The **Reset** method resets the internal state of the control. Property values are initialized to their internal defaults, open network connections will be closed and any handles allocated by the control will be released.

See Also

[Cancel Method](#), [Initialize Method](#), [Uninitialize Method](#)

Search Method

Search for a record using the specified keyword.

Syntax

object.Search([*Keyword*], [*SearchType*])

Parameters

Keyword

An optional string which specifies the keyword to search for. Typically this is the name of a domain, user handle or an email address. If this argument is omitted, the value of the **Keyword** property is used as the default value.

SearchType

An optional integer value which specifies the type of search to perform. If this argument is omitted, the value of the **SearchType** property is used as the default value. One of the following search types may be specified:

Value	Description
whoisSearchAny	Search for any value that matches the given keyword value
whoisSearchHandle	Search for a handle that matches the given keyword value
whoisSearchName	Search for a user name that matches the given keyword value
whoisSearchMailbox	Search for a user mailbox that matches the given keyword value

Return Value

A value of zero is returned if the method succeeds. Otherwise, a non-zero error code is returned which indicates the cause of the failure.

Remarks

The **Search** method submits the specified keyword and type of search to the server. The data returned by the server can be read using the **Read** method. Note that the text returned by a UNIX based server may only contain linefeeds at the end of each line of text, rather than the standard carriage return/linefeed used on Windows systems.

Example

The following example demonstrates how to use the **Search** method:

```
Dim strBuffer As String, strResults As String
Dim nRead As Long, nError As Long

' Connect to the InterNIC server and submit a search for the
' Internet Engineering Task Force (IETF) domain
nError = WhoisClient1.Connect("whois.internic.net")
If nError = 0 Then
    nError = WhoisClient1.Search("ietf.org", whoisSearchAny)
End If

' If an error occurs, display a message box and exit
If nError > 0 Then
    MsgBox WhoisClient1.LastErrorString, vbExclamation
```

```
Exit Sub
End If

' Read the data returned by the server and store it in
' a string buffer named strResults
Do
    nRead = WhoisClient1.Read(strBuffer, 2048)
    If nRead < 1 Then Exit Do
    strResults = strResults + strBuffer
Loop

' If there was an error reading the data, then report
' it to the user
If nRead = -1 Then
    MsgBox WhoisClient1.LastErrorString, vbExclamation
End If

' Disconnect from the server
WhoisClient1.Disconnect
```

See Also

[Keyword Property](#), [SearchType Property](#), [Connect Method](#), [Read Method](#)

Uninitialize Method

Uninitialize the control and release any system resources that were allocated.

Syntax

object.Uninitialize

Parameters

None.

Return Value

None.

Remarks

The **Uninitialize** method terminates any connection established by the control and resets the internal state of the control. This method is not typically used because any resources that have been allocated by an instance of the control will automatically be released when it is destroyed.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the control will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the control was created. An application should only call the **Uninitialize** method if it has explicitly called the **Initialize** method.

Whois Protocol Control Events

Event	Description
OnCancel	This event occurs when a blocking operation is canceled
OnConnect	This event occurs when a connection is established
OnDisconnect	This event occurs when a connection is terminated
OnError	This event occurs when a control error occurs
OnRead	This event occurs when data is available to be read
OnTimeout	This event occurs when a blocking operation times out

OnCancel Event

The **OnCancel** event is generated when a blocking operation is canceled.

Syntax

Sub *object_OnCancel* ([*Index As Integer*])

Remarks

This event occurs when a blocking operation on the socket, such as sending or receiving data, is canceled with the **Cancel** method. To assist in determining which operation was canceled, consult the **State** property.

See Also

[Cancel Method](#), [OnError Event](#), [OnTimeout Event](#)

OnConnect Event

The **OnConnect** event is generated when a connection is established.

Syntax

Sub *object_OnConnect* ([*Index As Integer*])

Remarks

The **OnConnect** event is generated when a connection is made with a server as a result of a **Connect** method call. This event is only triggered when the **Blocking** property is set to False.

See Also

[Blocking Property](#), [Connect Method](#), [OnDisconnect Event](#)

OnDisconnect Event

The **OnDisconnect** event is generated when a connection is terminated.

Syntax

Sub *object_OnDisconnect* ([*Index As Integer*])

Remarks

The **OnDisconnect** event is generated when the connection is terminated by the server. This event is only triggered when the **Blocking** property is set to False.

When the **OnDisconnect** event fires, it is possible that there may still be buffered data available to read from the server. Before disconnecting from the server, the application should attempt to read any remaining data until the **Read** method returns a value of zero, or returns an error indicating that the operation would block.

See Also

[Blocking Property](#), [IsConnected Property](#), [IsReadable Property](#), [Connect Method](#), [Disconnect Method](#), [Read Method](#), [OnConnect Event](#)

OnError Event

The **OnError** event is generated when a control error occurs.

Syntax

Sub *object_OnError* ([*Index As Integer*,] **ByVal** *ErrorCode As Variant*, **ByVal** *Description As Variant*)

Remarks

This event occurs when an error occurs during a control action. Errors not generated by the control itself, such as errors related to the programming language or general component errors, do not trigger this event.

The ***ErrorCode*** argument specifies the last error that has occurred. If the error is network related, the error code values returned by the control correspond to those returned by the standard Windows Sockets library.

The ***Description*** argument is a string that describes the error.

See Also

[LastError Property](#), [LastErrorString Property](#), [ThrowError Property](#)

OnRead Event

The **OnRead** event is generated when data is available to be read.

Syntax

Sub *object_OnRead* ([*Index As Integer*])

Remarks

The **OnRead** event is generated for non-blocking sockets when data is available to be read from the server. Use the **Read** method to read the data. This event is only triggered when the **Blocking** property is set to False.

See Also

[IsReadable Property](#), [Read Method](#), [Search Method](#)

OnTimeout Event

The **OnTimeout** event is fired when a blocking operation times out.

Syntax

Sub *object_OnTimeout* ([*Index As Integer*])

Remarks

The **OnTimeout** event is generated when a blocking socket operation, such as sending or receiving data, times out. To determine which operation was in progress when the timeout occurred, consult the **State** property. This event is only triggered when the **Blocking** property is set to True.

See Also

[Timeout Property](#), [OnCancel Event](#)
